and $k > 0$ is so large that $\beta \ll u \ll \alpha$, for all $u \in C^{1,0}(\overline{Q}_T)$ with $\|u\|_{C^{1,0}(\overline{Q}_T)} < M$. It is now easy to verify that α and β are, respectively, strict regular lower and upper solutions of (2.36).

For each $r > 1$, consider the modified problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = f_r(x,t,u,\nabla_x u) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega, \end{array} \tag{2.80}$$

where $f_r : Q_T \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is defined, for a.e. $(x,t) \in Q_T$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$, by

$$f_r(x,t,s,\xi) = \begin{cases} f(x,t,s,\xi) & \text{if } |s| < r, \\ \bigl(|s| - r\bigr)\bigl(\lambda_1 - \frac{1}{r}\bigr)s & \\ \quad + \bigl(r + 1 - |s|\bigr) f(x,t,s,\xi) & \text{if } r \leqslant |s| \leqslant r+1, \\ \bigl(\lambda_1 - \frac{1}{r}\bigr)s & \text{if } |s| > r+1. \end{cases}$$

Of course, f_r satisfies condition (C). Let us set

$$\mathcal{V} = \bigl\{ u \in C_B^{1,0}\bigl(\overline{Q}_T\bigr) \mid u \not\geqslant \alpha \text{ and } u \not\leqslant \beta \bigr\}.$$

CLAIM 3. *There exists $K > 0$ such that every solution $u \in \overline{\mathcal{V}}$ of* (2.80) *with $r > K$ satisfies $\|u\|_{C^{1,0}(\overline{Q}_T)} < K$.*

Assume by contradiction that, for every n, there exist $r_n > n$ and $u_n \in \overline{\mathcal{V}}$, solution of (2.80) for $r = r_n$, such that $\|u_n\|_{C^{1,0}(\overline{Q}_T)} \geqslant n$. As in Claim 1 of Proposition 2.36, we can write, for each $r > 1$,

$$f_r(x,t,s,\xi) = q_r(x,t,s,\xi)s + h_r(x,t,s,\xi)$$

for a.e. $(x,t) \in Q_T$ and every $(s,\xi) \in \mathbb{R} \times \mathbb{R}^N$, where q_r and h_r are L^p-Carathéodory functions satisfying

$$\lambda_1 - \frac{1}{r} \leqslant q_r(x,t,s,\xi) \leqslant \mu \quad \text{and} \quad \bigl|h_r(x,t,s,\xi)\bigr| \leqslant c(x,t),$$

for some $c \in L^p(Q_T)$ independent of r. Setting $v_n = u_n / \|u_n\|_{C^{1,0}(\overline{Q}_T)}$, we have that, possibly passing to a subsequence, $(v_n)_n$ converges weakly in $W_p^{2,1}(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to a solution v of

$$\begin{array}{ll} \partial_t v + A(x,t,\partial_x)v = q(x,t)v & \text{in } Q_T, \\ v = 0 & \text{on } \Sigma_T, \\ v(\cdot,0) = v(\cdot,T) & \text{in } \Omega, \end{array}$$

where $\|v\|_{C^{1,0}(\overline{Q}_T)} = 1$ and $q \in L^\infty(Q_T)$ satisfies $\lambda_1 \leqslant q(x,t) \leqslant \mu$ a.e. in Q_T. Proposition 2.52 implies that $q = \lambda_1$ a.e. in Q_T and $v = a\varphi_1$ for some $a \neq 0$. Hence, by Proposition 2.1, we conclude that, if $a > 0$, there exists $d > 0$ such that, for all n large enough,

$$u_n \geqslant d\|u_n\|_{C^{1,0}(\overline{Q}_T)} a\varphi_1 \gg \alpha$$

and, if $a < 0$, there exists $d > 0$ such that, for all n large enough,

$$u_n \leqslant d\|u_n\|_{C^{1,0}(\overline{Q}_T)} a\varphi_1 \ll \beta,$$

thus contradicting anyhow the assumption $u_n \in \overline{\mathcal{V}}$. This proves the claim.

Let us set $R = 1 + \max\{K, M, \|\alpha\|_{L^\infty(Q_T)}, \|\beta\|_{L^\infty(Q_T)}\}$. We first notice that α and β are strict lower and upper solutions of (2.80), with $r = R$. Indeed, otherwise there exists a solution $u \in \overline{\mathcal{V}}$ of (2.80), with $r = R$, which, by Claim 3, satisfies $\|u\|_{C^{1,0}(\overline{Q}_T)} < K$. Hence u is a solution of (2.36) too, contradicting the fact that α and β are strict lower and upper solutions of (2.36).

CLAIM 4. *Problem* (2.80), *with* $r = R$, *admits a lower solution* α_1 *and an upper solution* β_1 *such that* $\alpha_1 \leqslant \beta_1$ *and* $\alpha, \beta \in [\alpha_1, \beta_1]$.

We show how to build the upper solution, as the lower solution can be constructed similarly. Let z be the solution of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \left(\lambda_1 - \frac{1}{R}\right)u + (a_0 - \lambda_1)(R+2) & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array}$$

Choose, by Proposition 2.1, a constant $a > 0$ so large that $a\varphi_1 - z \geqslant 0$. We then easily verify that

$$\beta_1 = a\varphi_1 - z + R + 2$$

is an upper solution of (2.80), with $r = R$. This proves the claim.

We finally notice that the minimal and the maximal solution v and w of (2.36), we obtained in Claim 1, are minimal and maximal solutions in $\overline{\mathcal{V}} \cap [\alpha_1, \beta_1]$ of (2.80), with $r = R$. Theorem 2.42 implies that they are, respectively, $\mathcal{L}$-unstable from below and $\mathcal{L}$-unstable from above as solutions of (2.80), with $r = R$, and hence, by our choice of R, of (2.36). □

Stability and multiplicity of periodic solutions

We discuss in this section some relations between the stability properties and the multiplicity of solutions of (2.36). Propositions 2.45 and 2.47, which are direct consequences of Theorem 2.21 and Theorem 2.38, yield some results expressed in terms of $\mathcal{O}$-stability. Afterwards Propositions 2.46 and 2.48 provide an interpretation of these statements in terms of $\mathcal{L}$-stability.

PROPOSITION 2.45. *Assume* (D), (A), (C) *and* (N). *Let* u_1, u_2 *be solutions of* (2.36) *such that* $u_1 < u_2$, u_1 *is not properly* $\mathcal{O}$*-stable from above and* u_2 *is not properly* $\mathcal{O}$*-stable from below. Then there exists a solution* u_3 *of* (2.36) *with* $u_1 < u_3 < u_2$.

If moreover u_1 *is not* $\mathcal{O}$*-stable from above, then it is properly* $\mathcal{O}$*-unstable from above and there exists a solution* u_3 *of* (2.36), *with* $u_1 < u_3 < u_2$, *which is properly* $\mathcal{O}$*-stable from below. Similarly, if moreover* u_2 *is not* $\mathcal{O}$*-stable from below then it is properly* $\mathcal{O}$*-unstable from below and there exists a solution* u_3 *of* (2.36) *with* $u_1 < u_3 < u_2$ *which is properly* $\mathcal{O}$*-stable from above.*

Finally, if moreover both u_1 *is not* $\mathcal{O}$*-stable from above and* u_2 *is not* $\mathcal{O}$*-stable from below, then there exists a solution* u_3 *of* (2.36), *with* $u_1 < u_3 < u_2$, *which is* $\mathcal{O}$*-stable.*

PROOF. If u_1 is not properly $\mathcal{O}$-stable from above and u_2 is not properly $\mathcal{O}$-stable from below, then Theorem 2.21 implies that there exists a solution u_3 of (2.36), with $u_1 < u_3 < u_2$.

If u_1 is not $\mathcal{O}$-stable from above, then there exists $\varepsilon > 0$ such that every solution u of (2.36), with $u_1 < u < u_2$, satisfies $\|u - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \varepsilon$. By Lemma 2.16, there is a solution v of (2.36) such that $u_1 < v < u_2$, $\|v - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \varepsilon$ and there is no solution u of (2.36) with $u_1 < u < v$. Theorem 2.21 then implies that u_1 is properly $\mathcal{O}$-unstable from above and v is properly $\mathcal{O}$-stable from below.

Similarly, if u_2 is not $\mathcal{O}$-stable from below, then there exists a solution w of (2.36), with $u_1 < w < u_2$, such that there is no solution u of (2.36) with $w < u < u_2$. Theorem 2.21 implies that u_2 is properly $\mathcal{O}$-unstable from below and w is properly $\mathcal{O}$-stable from above.

Finally, if u_1 is not $\mathcal{O}$-stable from above and u_2 is not $\mathcal{O}$-stable from below, then there exist solutions v and w of (2.36), with $u_1 < v \leqslant w < u_2$, such that there is no solution u of (2.36) with either $u_1 < u < v$ or $w < u < u_2$. Further, v is properly $\mathcal{O}$-stable from below and w is properly $\mathcal{O}$-stable from above. Theorem 2.38 then implies that there exists a solution u_3 of (2.36), with $v \leqslant u_3 \leqslant w$, which is $\mathcal{O}$-stable. □

PROPOSITION 2.46. *Assume* (D), (A), (C) *and* (N). *Further, suppose that the second comparison principle holds. Let u_1, u_2 be solutions of* (2.36) *such that $u_1 < u_2$, u_1 is $\mathcal{L}$-unstable from above and u_2 is $\mathcal{L}$-unstable from below. Then there exists a solution u_3 of* (2.36) *with $u_1 \ll u_3 \ll u_2$ which is $\mathcal{L}$-stable.*

PROOF. Proposition 2.31 implies that u_1 is not $\mathcal{O}$-stable from above and u_2 is not $\mathcal{O}$-stable from below. Hence Proposition 2.45 yields the existence of a solution u_3 of (2.36) with $u_1 < u_3 < u_2$ which is $\mathcal{O}$-stable and therefore, by Proposition 2.31 again, it is $\mathcal{L}$-stable. □

REMARK 2.28. With reference to Proposition 2.46, we have that $u_1 \ll u_2$, u_1 is isolated from above in $C^{1,0}(\overline{Q}_T)$ and u_2 is isolated from below in $C^{1,0}(\overline{Q}_T)$, by Proposition 2.31. Hence, by Lemma 2.16, there exist solutions v and w of (2.36), with $u_1 \ll v \leqslant w \ll u_2$, such that there is no solution u satisfying either $u_1 < u < v$ or $w < u < u_2$. By Proposition 2.45 and Corollary 2.34, v is $\mathcal{L}$-asymptotically stable from below and w is $\mathcal{L}$-asymptotically stable from above.

The following results are dual versions of Proposition 2.45 and Proposition 2.46.

PROPOSITION 2.47. *Assume* (D), (A), (C) *and* (N). *Let u_1, u_2 be solutions of* (2.36) *such that $u_1 < u_2$, u_1 is not properly $\mathcal{O}$-unstable from above and u_2 is not properly $\mathcal{O}$-unstable from below. Then there exists a solution u_3 of* (2.36) *with $u_1 < u_3 < u_2$.*

If moreover u_1 is not $\mathcal{O}$-unstable from above, then it is properly $\mathcal{O}$-stable from above and there exists a solution u_3 of (2.36), *with $u_1 < u_3 < u_2$, which is properly $\mathcal{O}$-unstable from below. Similarly, if moreover u_2 is not $\mathcal{O}$-unstable from below, then it is properly $\mathcal{O}$-stable from below and there exists a solution u_3 of* (2.36), *with $u_1 < u_3 < u_2$, which is properly $\mathcal{O}$-unstable from above.*

PROOF. If u_1 is not properly $\mathcal{O}$-unstable from above and u_2 is not properly $\mathcal{O}$-unstable from below, then Theorem 2.21 implies that there exists a solution u_3 of (2.36) with $u_1 < u_3 < u_2$.

If u_1 is not $\mathcal{O}$-unstable from above, then there exists $\varepsilon > 0$ such that every solution u of (2.36) with $u_1 < u < u_2$ satisfies $\|u - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \varepsilon$. By Lemma 2.16, there exists a solution v of (2.36) such that $u_1 < v < u_2$, $\|v - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \varepsilon$ and there is no solution u of (2.36) with $u_1 < u < v$. Moreover, Theorem 2.21 implies that u_1 is properly $\mathcal{O}$-stable from above and v is properly $\mathcal{O}$-unstable from below.

Similarly, if u_2 is not $\mathcal{O}$-unstable from below, then there exists a solution w of (2.36) with $u_1 < w < u_2$ and there is no solution u of (2.36) such that $w < u < u_2$. Theorem 2.21 implies then that u_2 is properly $\mathcal{O}$-stable from below and w is properly $\mathcal{O}$-unstable from above. □

PROPOSITION 2.48. *Assume* (D), (A), (C) *and* (N). *Let* u_1, u_2 *be solutions of* (2.36) *such that* $u_1 < u_2$, u_1 *is* $\mathcal{L}$*-stable from above and* u_2 *is* $\mathcal{L}$*-stable from below. Then there exists a solution* u_3 *of* (2.36) *with* $u_1 < u_3 < u_2$.

If moreover u_1 *is isolated from above in* $C^{1,0}(\overline{Q}_T)$, *then there exists a solution* u_3 *of* (2.36), *with* $u_1 < u_3 < u_2$, *which is* $\mathcal{L}$*-unstable from below. Similarly, if moreover* u_2 *is isolated from below in* $C^{1,0}(\overline{Q}_T)$, *then there exists a solution* u_3 *of* (2.36), *with* $u_1 < u_3 < u_2$, *which is* $\mathcal{L}$*-unstable from above.*

PROOF. If we assume that there is no solution u_3 of (2.36), with $u_1 < u_3 < u_2$, then by Theorem 2.21 either u_1 is properly $\mathcal{O}$-unstable from above or u_2 is properly $\mathcal{O}$-unstable from below. In the former case there is a sequence $(\alpha_n)_n$ of proper regular lower solutions of (2.36) such that, for every n, $u_1 < \alpha_n < u_2$, $\alpha_n = 0$ on Σ_T and $\|\alpha_n - u_1\|_e \to 0$, as $n \to +\infty$. Fix $t_0 \in]0, T[$. Then, for every $\delta > 0$, there exists n such that, setting $u_0 = \alpha_n(\cdot, t_0)$, we have $u_0 \in W_p^{2-2/p}(\Omega)$, $u_0 = 0$ on $\partial\Omega$, $u_0 \geqslant u_1(\cdot, t_0)$ and $\|u_0 - u_1(\cdot, t_0)\|_e < \delta$. By Proposition 2.13, problem (2.13) has a nonextendible solution u, satisfying $u > u_1$ in $\overline{\Omega} \times [t_0, +\infty[$ and $\lim_{t\to+\infty} \|u(\cdot, t) - u_2(\cdot, t)\|_e = 0$. Therefore, we get $\limsup_{t\to+\infty} \|u(\cdot, t) - u_1(\cdot, t)\|_e \geqslant \frac{1}{2}\|u_1 - u_2\|_e$, thus contradicting the $\mathcal{L}$-stability from above of u_1. Similarly, we verify that u_2 cannot be properly $\mathcal{O}$-unstable from below. Accordingly, there exists a solution u_3 of (2.36), with $u_1 < u_3 < u_2$.

Suppose further that u_1 is isolated from above in $C^{1,0}(\overline{Q}_T)$, i.e. there is $\delta > 0$ such that every solution u of (2.36), with $u > u_1$, satisfies $\|u - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \delta$, then by Lemma 2.16, there exists a solution u_3 of (2.36), satisfying $u_3 \in [u_1, u_2]$ and $\|u_3 - u_1\|_{C^{1,0}(\overline{Q}_T)} \geqslant \delta$, such that there is no solution u, with $u_1 < u < u_3$. Arguing as in the previous step, we see that u_3 is properly $\mathcal{O}$-unstable from below. Hence, arguing as in Proposition 2.40, we conclude that u_3 is $\mathcal{L}$-unstable from below. Similarly, if we suppose further that u_2 is isolated from below, we derive the existence of a solution u_3 of (2.36) which is $\mathcal{L}$-unstable from above. □

REMARK 2.29. We stress again that the conclusions of Proposition 2.48 are obtained without requiring the validity of any comparison principle. On the other hand, if we assume in Proposition 2.48 that the second comparison principle holds, then u_1 is $\mathcal{L}$-asymptotically stable from above, provided it is isolated from above, and u_2 is $\mathcal{L}$-asymptotically stable from below, provided it is isolated from below. The $\mathcal{L}$-asymptotic stability from above of u_1 easily follows from Corollary 2.34. Indeed, any solution u_3 of (2.36), satisfying $u_1 \ll u_3 \leqslant u_2$ and such that there is no solution u with $u_1 < u < u_3$, is properly $\mathcal{O}$-unstable from below and hence there exist proper regular upper solutions β with $u_1 \ll \beta \ll u_3$. The analogous conclusion about u_2 is obtained in a similar way.

2.7. *Appendix: The principal eigenvalue*

This appendix is devoted to the definition and the discussion of some properties of the principal eigenvalue of the periodic problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \lambda u & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega. \end{array} \tag{2.81}$$

Our first result is an extension of a similar statement proved in [82] (see also [27,18]) under stronger regularity conditions.

PROPOSITION 2.49. *Assume* (D) *and* (A). *Let $p > N + 2$ be fixed. Then there exist a number $\lambda_1 > 0$ and a function $\varphi_1 \in W^{2,1}_{p,B}(Q_T)$ such that*

$$L\varphi_1 = \lambda_1\varphi_1,$$

where L is defined by (2.47) *and* (2.48). *Moreover, the following conclusions hold*:

(i) $\varphi_1 \gg 0$;
(ii) *if $L\psi = \lambda_1\psi$ for some $\psi \in W^{2,1}_{p,B}(Q_T)$, then $\psi = k\varphi_1$ for some $k \in \mathbb{R}$*;
(iii) *if $L\psi = \lambda\psi$ for some $\psi \in W^{2,1}_{p,B}(Q_T)$, with $\psi > 0$, then $\lambda = \lambda_1$*;
(iv) *for every $\lambda < \lambda_1$ and $h \in L^p(Q_T)$, the problem $Lu - \lambda u = h$ has a unique solution.*

PROOF. Let us introduce the operator $S : C^{1,0}_B(\overline{Q}_T) \to C^{1,0}_B(\overline{Q}_T)$ which sends any $h \in C^{1,0}_B(\overline{Q}_T)$ onto the unique solution $u \in C^{1,0}_B(\overline{Q}_T)$ of (2.46), with $\sigma = 0$. S is compact and strongly positive with respect to the order induced in $C^{1,0}_B(\overline{Q}_T)$ by the cone $K = \{u \in C^{1,0}_B(\overline{Q}_T) \mid u \geqslant 0\}$. Observe that $\overset{\circ}{K} = \{u \in C^{1,0}_B(\overline{Q}_T) \mid u \gg 0\}$. The strong form of Krein–Rutman Theorem (see, e.g., [153, Theorem 7C]) yields the existence of $\varphi_1 \in W^{2,1}_{p,B}(Q_T)$ satisfying $L\varphi_1 = \lambda_1\varphi_1$, with λ_1 the reciprocal of the spectral radius $r(S)$ of S, as well as conditions (i)–(iii). Finally, condition (iv) is a consequence of Proposition 2.14, if $\lambda \leqslant 0$. For $\lambda \in \,]0, \lambda_1[$, let us consider the extension $\tilde{S}$ of S to $L^p(Q_T)$, i.e. the operator $\tilde{S} : L^p(Q_T) \to L^p(Q_T)$ which sends any $h \in L^p(Q_T)$ onto the unique solution $u \in L^p(Q_T)$ of (2.46), with $\sigma = 0$. $\tilde{S}$ is compact and positive with respect to the order induced in $L^p(Q_T)$ by the cone $\tilde{K} = \{u \in L^p(Q_T) \mid u \geqslant 0\}$. By the weak form of Krein–Rutman Theorem (see, e.g., [153, Proposition 7.26]), the spectral radius $r(\tilde{S})$ of $\tilde{S}$ is an eigenvalue of $\tilde{S}$, with eigenfunction $\tilde{\varphi}_1 \in L^p(Q_T)$ satisfying $\tilde{\varphi}_1(x,t) > 0$ a.e. in Q_T. Since, by condition (iii), $r(\tilde{S}) = r(S)$, the result follows from the Fredholm Alternative (see, e.g., [144, Theorem 1.L]) applied to the operator $\tilde{S}$. □

PROPOSITION 2.50. *Assume* (D) *and* (A). *Let* $q_1, q_2 \in L^\infty(Q_T)$ *be such that* $q_1(x,t) \leqslant q_2(x,t)$ *a.e. in* Q_T *and let* u_1, u_2 *be nontrivial solutions of* $Lu_1 = q_1 u_1$ *and* $Lu_2 = q_2 u_2$, *respectively. If* $u_2 \geqslant 0$, *then* $q_1 = q_2$ *and* $u_1 = cu_2$, *for some* $c \in \mathbb{R}$.

PROOF. Since $Lu_2 - q_2 u_2 \geqslant 0$ and $u_2 > 0$, we deduce from Remark 2.7 that $u_2 \gg 0$. If we set $c = \min\{d \in \mathbb{R} \mid du_2 \geqslant u_1\}$ and $v = cu_2 - u_1$, as $v \geqslant 0$, we get $Lv - q_1 v \geqslant 0$ and hence either $v \gg 0$ or $v = 0$. The minimality of c actually yields $v = cu_2 - u_1 = 0$. This finally implies $0 = Lv - q_1 v = (q_2 - q_1)cu_2$ and therefore $q_1 = q_2$. □

PROPOSITION 2.51. *Assume* (D) *and* (A). *Let* $q \in L^\infty(Q_T)$ *satisfy* $q(x,t) \leqslant \lambda_1$ *a.e. in* Q_T *and* $q(x,t) < \lambda_1$ *on a subset of positive measure. Then the problem* (2.79) *has a unique solution, for any given* $h \in L^p(Q_T)$ *with* $p > N+2$.

PROOF. Setting $q_1 = q$ and $q_2 = \lambda_1$, Proposition 2.50 implies that the homogeneous equation $Lu = qu$ has only the trivial solution. The Fredholm Alternative applied to the operator $T = q\tilde{S} : L^p(Q_T) \to L^p(Q_T)$, where $\tilde{S}$ has been defined in the proof of Proposition 2.49, yields the conclusion. □

PROPOSITION 2.52. *Assume* (D) *and* (A). *Then there exists* $\mu > \lambda_1$ *such that, if* $q \in L^\infty(Q_T)$ *satisfies* $\lambda_1 \leqslant q(x,t) \leqslant \mu$ *a.e. in* Q_T *and* $\lambda_1 < q(x,t)$ *on a subset of positive measure, problem* (2.79) *has a unique solution, for any given* $h \in L^p(Q_T)$ *with* $p > N+2$.

PROOF. Let us show that there exists $\mu > \lambda_1$ such that, if $q \in L^\infty(Q_T)$ satisfies $\lambda_1 \leqslant q(x,t) \leqslant \mu$ a.e. in Q_T and $\lambda_1 < q(x,t)$ on a set of positive measure, the problem

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = q(x,t)u & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega, \end{array}$$

has only the trivial solution. Indeed, assume by contradiction that, for every n, there exist $q_n \in L^\infty(Q_T)$, satisfying $\lambda_1 \leqslant q_n(x,t) \leqslant \lambda_1 + 1/n$ a.e. in Q_T and $\lambda_1 < q_n(x,t)$ on a set of positive measure, and a solution u_n of

$$\begin{array}{ll} \partial_t u_n + A(x,t,\partial_x)u_n = q_n(x,t)u_n & \text{in } Q_T, \\ u_n = 0 & \text{on } \Sigma_T, \\ u_n(\cdot,0) = u_n(\cdot,T) & \text{in } \Omega, \end{array}$$

with $\|u_n\|_{C^{1,0}(\overline{Q}_T)} = 1$. Proposition 2.50 implies that each u_n changes sign in Q_T. Possibly passing to a subsequence, $(u_n)_n$ converges weakly in $W_p^{2,1}(Q_T)$ and strongly in $C^{1,0}(\overline{Q}_T)$ to a nontrivial solution u of

$$\begin{array}{ll} \partial_t u + A(x,t,\partial_x)u = \lambda_1 u & \text{in } Q_T, \\ u = 0 & \text{on } \Sigma_T, \\ u(\cdot,0) = u(\cdot,T) & \text{in } \Omega, \end{array}$$

which, therefore, satisfies either $u \gg 0$, or $u \ll 0$. Hence Proposition 2.1 yields, for n large enough, either $u_n \gg 0$, or $u_n \ll 0$, which is a contradiction. The Fredholm Alternative applied to the operator $T = q\tilde{S} : L^p(Q_T) \to L^p(Q_T)$, where $\tilde{S}$ has been defined in the proof of Proposition 2.49, yields the conclusion. □

In this chapter we present the bifurcation theory of limit cycles of planar systems with relatively simple dynamics. The theory studies the changes of orbital behavior in the phase space, especially the number of limit cycles as we vary the parameters of the system. This theory has been considered by many mathematicians starting with Poincaré who first introduced the notion of limit cycles. A fundamental step towards modern bifurcation theory in differential equations occurred with the definition of structural stability and the classification of structurally stable systems in the plane in 1937 developed by Andronov, Leontovich and Pontryagin. More precisely, Andronov and Pontryagin introduced the notion of a rough system and presented the necessary and sufficient conditions of roughness for systems on the plane. Almost at the same time, Andronov and Leontovich carried out a systematic classification of all principal bifurcations of limit cycles on the plane for the simplest nonrough systems. A further development of the theory had taken yet another direction, namely by selecting bifurcation sets of codimension one for primary bifurcations, and of arbitrary codimension in the general case for degenerate bifurcations. In the two-dimensional case, as was proved in Andronov et al. [2], rough systems compose an open and dense set in the space of all systems on a plane. The nonrough systems fill the boundaries between different regions of structural stability in this space.

In the following sections we concentrate on an in-depth study of limit cycles with general methods of both local and global bifurcations in high codimensional case. Many results are closely related to the second part of Hilbert's 16th problem which concerns with the number and location of limit cycles of a planar polynomial vector field of degree n posed in 1901 by Hilbert [73].

1. Limit cycle and its perturbations

1.1. *Basic notations*

Consider a planar system defined on a region $G \subset \mathbb{R}^2$ of the form

$$\dot{x} = f(x), \tag{1.1}$$

where $f : G \to \mathbb{R}^2$ is a C^r function, $r \geqslant 1$. Then for any point $x_0 \in G$ (1.1) has a unique solution $\varphi(t, x_0)$ satisfying $\varphi(0, x_0) = x_0$. Let $\varphi^t(x_0) = \varphi(t, x_0)$. The family of the transformations $\varphi^t : G \to \mathbb{R}^2$ satisfy the following properties:

(i) $\varphi^0 = \mathrm{Id}$;
(ii) $\varphi^{t+s} = \varphi^t \circ \varphi^s$.

The function φ is called the flow generated by (1.1) or by the vector field f. Let $I(x_0)$ denote the maximal interval of definition of $\varphi(t, x_0)$ in t. If $x_0 \in G$ is such that $\varphi(t, x_0)$ is constant for all $t \in I(x_0)$, then $f(x_0) = 0$. In this case, x_0 is called *a singular point* of (1.1). A point that is not singular is called *a regular point*.

For any regular point $x_0 \in G$, the solution $\varphi(t, x_0)$ defines two planar curves as follows:

$$\gamma^+(x_0) = \{\varphi(t, x_0) \colon t \in I(x_0), t \geqslant 0\}, \quad \gamma^-(x_0) = \{\varphi(t, x_0) \colon t \in I(x_0), t \leqslant 0\},$$

which are called respectively the *positive* and the *negative orbit* of (1.1) through x_0. The union $\gamma(x_0) = \gamma^+(x_0) \cup \gamma^-(x_0)$ is called the *orbit* of (1.1) through x_0. The theorem about the existence and uniqueness of solutions ensures that there is one and only one orbit through any point in G. A *periodic orbit* of (1.1) is an orbit which is a closed curve. The minimal positive number satisfying $\varphi(T, x_0) = x_0$ is said to be the *period* of the periodic orbit $\gamma(x_0)$. Obviously, $\gamma(x_0)$ is a periodic orbit of period T if and only if the corresponding representation $\varphi(t, x_0)$ is a periodic solution of the same period.

DEFINITION 1.1. A periodic orbit of (1.1) is called a *limit cycle* if it is the only periodic orbit in a neighborhood of it. In other words, a limit cycle is an isolated periodic orbit in the set of all periodic orbits.

Now let (1.1) have a limit cycle L: $x = u(t), 0 \leqslant t \leqslant T$. Since (1.1) is autonomous, for any given point $p \in L$ we may suppose $p = u(0)$, and hence, $u(t) = \varphi(t, p)$. Further, for definiteness, let L be oriented clockwise. Introduce a unit vector

$$Z_0 = \frac{1}{|f(p)|}\big(-f_2(p), f_1(p)\big)^{\mathrm{T}}.$$

Then there exists a cross section l of (1.1) which passes through p and is parallel to Z_0. Clearly, a point $x_0 \in l$ near p can be written as $x_0 = p + aZ_0, a = (x_0 - p)^{\mathrm{T}} Z_0 \in \mathbb{R}$.

LEMMA 1.1. *There exist a constant* $\varepsilon > 0$ *and* C^r *functions* P *and* $\tau : (-\varepsilon, \varepsilon) \to \mathbb{R}$ *with* $P(0) = 0$ *and* $\tau(0) = T$ *such that*

$$\varphi\big(\tau(a), p + aZ_0\big) = p + P(a)Z_0 \in l, \quad |a| < \varepsilon. \tag{1.2}$$

PROOF. Define $Q(t, a) = [f(p)]^{\mathrm{T}}(\varphi(t, p + aZ_0) - p)$. We have

$$Q(T, 0) = 0, \qquad Q_t(T, 0) = \big|f(p)\big|^2 > 0.$$

Note that Q is C^r for (t, a) near $(T, 0)$. The implicit function theorem implies that a C^r function $\tau(a) = T + \mathrm{O}(a)$ exists satisfying

$$Q\big(\tau(a), a\big) = 0 \quad \text{or} \quad \big[f(p)\big]^{\mathrm{T}}\big(\varphi\big(\tau(a), p + aZ_0\big) - p\big) = 0.$$

It follows that the vector $\varphi(\tau(a), p + aZ_0) - p$ is parallel to Z_0. Hence, it can be rewritten as $\varphi(\tau(a), p + aZ_0) - p = P(a)Z_0$, where $P(a) = Z_0^{\mathrm{T}}(\varphi(\tau(a), p + aZ_0) - p)$. It is obvious that $P \in C^r$ for $|a|$ small with $P(0) = 0$. This ends the proof. □

The above proof tells us that the function τ is the time of the first return to l. By Definition 1.1, the periodic orbit L is a limit cycle if and only if $P(a) \neq a$ for $|a| > 0$ sufficiently small.

DEFINITION 1.2. The function $P : (-\varepsilon, \varepsilon) \to \mathbb{R}$ defined by (1.2) is called a *Poincaré map* or return map of (1.1) at $p \in l$.

For convenience, we sometimes use the notation $P : l \to l$.

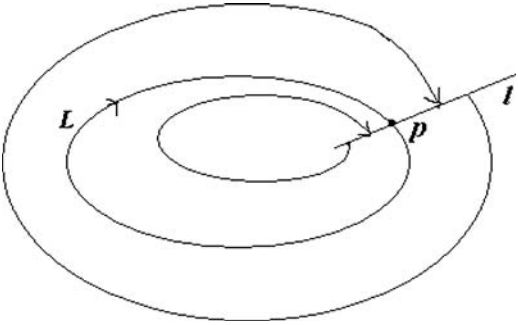

Fig. 1. Behavior of a stable limit cycle.

DEFINITION 1.3. The limit cycle L is said to be *outer stable* (*outer unstable*) if for $a > 0$ sufficiently small,

$$a\bigl(P(a) - a\bigr) < 0\ (> 0).$$

The limit cycle L is said to be *inner stable* (*inner unstable*) if the inequality above holds for $-a > 0$ sufficiently small. A limit cycle is called *stable* if it is both inner and outer stable. A limit cycle is called *unstable* if it is not stable.

For example, if L is stable, then the orbits near it behave like the phase portrait as shown in Fig. 1.

Let $P^k(a)$ denote the kth iterate of a under P. It is evident that $\{P^k(a)\}$ is monotonic in k and $P^k(a) > 0$ (< 0) for $a > 0$ (< 0). Thus, it is easy to see that L is outer stable if and only if $P^k(a) \to 0$ as $k \to \infty$ for all $a > 0$ sufficiently small. Similar conclusions hold for outer unstable, inner stable and inner unstable cases.

REMARK 1.1. If the limit cycle L is oriented anti-clockwise we can define its stability in a similar manner by using the Poincaré map P defined by (1.2). For instance, it is said to be inner stable (inner unstable) if $a(P(a) - a) < 0$ (> 0) for $a > 0$ sufficiently small.

DEFINITION 1.4. The limit cycle L is said to be *hyperbolic or of multiplicity one* if $P'(0) \neq 1$. It is said to have *multiplicity* k, $2 \leqslant k \leqslant r$, if $P'(0) = 1, P^{(j)}(0) = 0$, $j = 2, \dots, k-1$, $P^{(k)}(0) \neq 0$.

By Definition 1.3, one can see that L is stable (unstable) if $|P'(0)| < 1$ (> 1).

1.2. *Multiplicity, stability and their property*

Next, we give formulas for $P'(0)$ and $P''(0)$. For the purpose, let

$$v(\theta) = \frac{u'(\theta)}{|u'(\theta)|} = \bigl(v_1(\theta), v_2(\theta)\bigr)^{\mathrm{T}}, \qquad Z(\theta) = \bigl(-v_2(\theta), v_1(\theta)\bigr)^{\mathrm{T}},$$

and introduce a transformation of coordinates of the form

$$x = u(\theta) + Z(\theta)b, \quad 0 \leqslant \theta \leqslant T,\ |b| < \varepsilon. \tag{1.3}$$

LEMMA 1.2. *The transformation* (1.3) *carries* (1.1) *into the system*

$$\frac{\mathrm{d}\theta}{\mathrm{d}t} = 1 + g_1(\theta, b), \qquad \frac{\mathrm{d}b}{\mathrm{d}t} = A(\theta)b + g_2(\theta, b), \tag{1.4}$$

where

$$\begin{aligned}
&A(\theta) = Z^{\mathrm{T}}(\theta) f_x\big(u(\theta)\big)Z(\theta) = \operatorname{tr} f_x\big(u(\theta)\big) - \frac{\mathrm{d}}{\mathrm{d}\theta}\ln\big|f\big(u(\theta)\big)\big|,\\
&g_1(\theta, b) = h(\theta, b)\big[f\big(u(\theta) + Z(\theta)b\big) - f\big(u(\theta)\big)\big] - h(\theta, b)Z'(\theta)b,\\
&g_2(\theta, b) = Z^{\mathrm{T}}(\theta)\big[f\big(u(\theta) + Z(\theta)b\big) - f\big(u(\theta)\big) - f_x\big(u(\theta)\big)Z(\theta)b\big],\\
&h(\theta, b) = \big(\big|f\big(u(\theta)\big)\big| + v^{\mathrm{T}}(\theta)Z'(\theta)b\big)^{-1}v^{\mathrm{T}}(\theta),
\end{aligned}$$

and tr $f_x(u(\theta))$ *denotes the trace of the matrix* $f_x(u(\theta))$, *which is called the divergence of the vector field* f *evaluated at* $u(\theta)$.

PROOF. By (1.3) and (1.1) we have

$$\big(u' + Z'b\big)\frac{\mathrm{d}\theta}{\mathrm{d}t} + Z\frac{\mathrm{d}b}{\mathrm{d}t} = f(u + Zb). \tag{1.5}$$

In order to obtain (1.4) we need to solve $\frac{\mathrm{d}\theta}{\mathrm{d}t}$ and $\frac{\mathrm{d}b}{\mathrm{d}t}$ from (1.5). First, multiplying (1.5) by v^{T} from the left-hand side and using

$$v^{\mathrm{T}}Z = 0, \qquad v^{\mathrm{T}}f(u) = v^{\mathrm{T}}u' = \big|u'\big| = \big|f(u)\big|,$$

we can obtain

$$\frac{\mathrm{d}\theta}{\mathrm{d}t} = \big[\big|f(u)\big| + v^{\mathrm{T}}Z'b\big]^{-1}v^{\mathrm{T}}f(u + Zb) = h(\theta, b)f(u + Zb).$$

Note that

$$h(\theta, b)f(u) = h(\theta, b)\big[f(u) + Z'b\big] - h(\theta, b)Z'b = 1 - h(\theta, b)Z'b.$$

It follows that

$$h(\theta, b)f(u + Zb) = h(\theta, b)\big[f(u + Zb) - f(u)\big] - h(\theta, b)Z'b + 1.$$

Then the first equation in (1.4) follows.

Now multiplying (1.5) by Z^{T} from the left and using

$$Z^{\mathrm{T}}Z=1, \qquad Z^{\mathrm{T}}f(u)=0, \qquad Z^{\mathrm{T}}Z'=\frac{1}{2}\left(|v|^2\right)'=0,$$

we obtain

$$\frac{\mathrm{d}b}{\mathrm{d}t}=Z^{\mathrm{T}}\left[f(u+Zb)-f(u)-f_x(u)Zb\right]+Z^{\mathrm{T}}f_x(u)Zb.$$

It is direct to prove that

$$Z^{\mathrm{T}}f_x(u)Z=\operatorname{tr}f_x(u)-\frac{\mathrm{d}}{\mathrm{d}\theta}\ln\left|f(u)\right|.$$

Then the second equation of (1.4) follows. This finishes the proof. $\square$

Set

$$B(\theta)=\left[f_x(u+Zb)\right]_b'\Big|_{b=0}, \quad C(\theta)=v^{\mathrm{T}}\left[f_x(u)Z-Z'(\theta)\right], \tag{1.6}$$

and

$$R(\theta,b)=\frac{A(\theta)b+g_2(\theta,b)}{1+g_1(\theta,b)}.$$

Then by Lemma 1.2, we can write

$$\begin{aligned}R(\theta,b)&=A(\theta)b+\frac{1}{2}\left[Z^{\mathrm{T}}BZ-\frac{2AC}{|f(u)|}\right]b^2+\mathrm{O}\left(b^3\right)\\&=A(\theta)b+\frac{1}{2}A_1(\theta)b^2+\mathrm{O}\left(b^3\right).\end{aligned} \tag{1.7}$$

For $|b|$ small we have from (1.4)

$$\frac{\mathrm{d}b}{\mathrm{d}\theta}=R(\theta,b) \tag{1.8}$$

which is a T-periodic equation. From Lemma 1.2 we know that the function R is C^{r-1} in (θ,b) and C^r in b. Let $b(\theta,a)$ denote the solution of (1.8) with $b(0,a)=a$. We have:

LEMMA 1.3. *$P(a)=b(T,a)$.*

PROOF. Consider the equation

$$\frac{\mathrm{d}\theta}{\mathrm{d}t}=1+g_1\left(\theta,b(\theta,a)\right).$$

It has a unique solution $\theta = \theta(t, a)$ satisfying $\theta(0, a) = 0$. From (1.7) it implies $b(\theta, 0) = 0$. This yields $\theta(T, 0) = T$, $\frac{\partial\theta}{\partial t}(T, 0) = 1$. Hence, by the implicit function theorem a unique function $\tilde{\tau}(a) = T + \mathrm{O}(a)$ exists such that $\theta(\tilde{\tau}, a) = T$.

For $x_0 = u(0) + Z(0)a$, we have by (1.3)

$$\varphi(t, x_0) = u\big(\theta(t, a)\big) + Z\big(\theta(t, a)\big)b\big(\theta(t, a), a\big).$$

In particular,

$$\varphi(\tilde{\tau}, x_0) = u(T) + Z(T)b(T, a) = u(0) + Z(0)b(T, a).$$

Thus, it follows from Lemma 1.1 that $\tau = \tilde{\tau}$ and $P(a) = b(T, a)$.

The proof is completed. □

For $|a|$ small we can write

$$b(\theta, a) = b_1(\theta)a + b_2(\theta)a^2 + \mathrm{O}\big(a^3\big),$$

where $b_1(0) = 1, b_2(0) = 0$. By (1.7) and (1.8) one can obtain $b_1' = Ab_1, b_2' = Ab_2 + \frac{1}{2}A_1b_1^2$, which give

$$b_1(\theta) = \exp\int_0^\theta A(s)\,\mathrm{d}s, \qquad b_2(\theta) = b_1(\theta)\int_0^\theta \frac{1}{2}A_1(s)b_1(s)\,\mathrm{d}s.$$

Then by Lemma 1.3 we have

$$P'(0) = b_1(T) = \exp\int_0^T A(s)\,\mathrm{d}s = \exp\int_0^T \operatorname{tr} f_x\big(u(t)\big)\,\mathrm{d}t,$$

$$P''(0) = 2b_2(T) = b_1(T)\int_0^T A_1(s)b_1(s)\,\mathrm{d}s.$$

Thus, noting (1.7) we obtain the following theorem.

THEOREM 1.1. *Suppose P is a Poincaré map of* (1.1) *at $p \in L$. Then*

$$\text{(i)}\quad P'(0) = \exp\oint_L \operatorname{div} f\,\mathrm{d}t, \quad \operatorname{div} f = \operatorname{tr} f_x,$$

$$\text{(ii)}\quad P''(0) = P'(0)\int_0^T \mathrm{e}^{\int_0^t A(s)\,\mathrm{d}s}\left[Z^T(t)B(t)Z(t) - \frac{2A(t)C(t)}{|f(u(t))|}\right]\mathrm{d}t.$$

Hence, L is stable (*unstable*) *if $I(L) = \oint_L \operatorname{div} f\,\mathrm{d}t < 0$ (> 0).*

We remark that Theorem 1.1 remains true in the case of counter clockwise orientation of L.

EXAMPLE 1.1. Consider the quadratic system

$$
\begin{aligned}
\dot{x} &= -y(1+cx) - \bigl(x^2+y^2-1\bigr),\\
\dot{y} &= x(1+cx), \quad 0<c<1.
\end{aligned}
$$

This system has the circle L: $x^2+y^2=1$ as its limit cycle. We claim that the cycle is unstable.

In fact, we have

$$
\begin{aligned}
I(L) &= \oint_L (-2x-cy)\,\mathrm{d}t = \oint_L \left(\frac{c\,\mathrm{d}x}{1+cx} - \frac{2\,\mathrm{d}y}{1+cx}\right)\\
&= \iint_{x^2+y^2\leqslant 1} \frac{\mathrm{d}x\,\mathrm{d}y}{(1+cx)^2} > 0.
\end{aligned}
$$

EXAMPLE 1.2. The system

$$
\begin{aligned}
\dot{x} &= -y - x\bigl(x^2+y^2-1\bigr)^2,\\
\dot{y} &= x - y\bigl(x^2+y^2-1\bigr)^2
\end{aligned}
$$

has a unique limit cycle given by L: $(x,y)=(\cos t,\sin t), 0\leqslant t\leqslant 2\pi$. For the system, it is easy to see that $v(\theta)=(-\sin\theta,\cos\theta)^{\mathrm{T}}$, $Z(\theta)=(-\cos\theta,-\sin\theta)^{\mathrm{T}}$. By Lemma 1.2 and (1.6) we then have

$$
A(\theta)=0, \quad B(\theta)=\begin{pmatrix} 8\cos^2\theta & 8\sin\theta\cos\theta\\ 8\sin\theta\cos\theta & 8\sin^2\theta \end{pmatrix}.
$$

Thus from Theorem 1.1 it follows $P'(0)=1$, $P''(0)=16\pi$. This shows that L is a limit cycle of multiplicity 2.

From (1.6) and formulas for $P'(0)$ and $P''(0)$ in Theorem 1.1 the derivatives $P'(0)$ and $P''(0)$ are independent of the choice of the cross section l. This fact suggests that the stability and the multiplicity of a limit cycle should have the same property. Below we will prove this in detail even if the cross section l is taken as a C^r smooth curve.

To do this, let L be a limit cycle of (1.1) as before and let l_1 be a C^r curve which has an intersection point $p_1\in L$ with L and is not tangent to L at p_1. Then it can be represented as

$$
l_1\colon\ x=p_1+q(a), \quad q(0)=0,\ \det\bigl(f(p_1),q'(0)\bigr)>0,
$$

where $q:(-\varepsilon,\varepsilon)\to\mathbb{R}$ is C^r for a constant $\varepsilon>0$. The condition $\det(f(p_1),q'(0))>0$ means that the point $p_1+q(a)$ is outside L if and only if $a>0$.

In the same way as Lemma 1.1 we can prove that there exist two C^r functions

$$
P_1,\tau_1:(-\varepsilon,\varepsilon)\to\mathbb{R}, \quad P_1(0)=0, \quad \tau_1(0)=T
$$

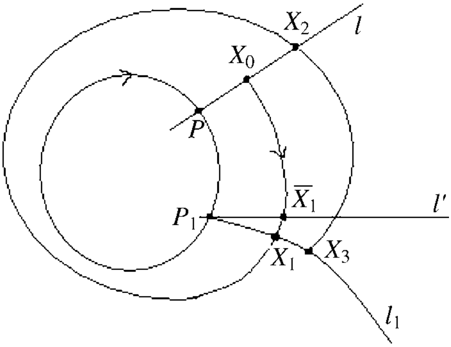

Fig. 2. Two Poincaré maps.

such that

$$\varphi\big(\tau_1(a), p_1 + q(a)\big) = p_1 + q\big(P_1(a)\big) \in l_1. \tag{1.9}$$

This yields another Poincaré map $P_1 : (-\varepsilon, \varepsilon) \to \mathbb{R}$.

LEMMA 1.4. *Let P and P_1 be two Poincaré maps defined by* (1.2) *and* (1.9), *respectively. Then there exists a C^r function $h_1 : (-\varepsilon, \varepsilon) \to \mathbb{R}$ with $h_1(0) = 0$, $h_1'(0) > 0$ such that $h_1 \circ P = P_1 \circ h_1$.*

PROOF. Since $p = u(0)$ we can suppose $p_1 = u(t_1)$ for some $t_1 \in [0, T)$. Similar to Lemma 1.1 again, there exist two C^r functions h_1 and τ^*, both from $(-\varepsilon, \varepsilon)$ to $\mathbb{R}$, with $h_1(0) = 0$ and $\tau^*(0) = t_1$ such that

$$\varphi\big(\tau^*(a), p + aZ_0\big) = p_1 + q\big(h_1(a)\big) \in l_1. \tag{1.10}$$

See Fig. 2. Let $x_0 = p + aZ_0$, $x_1 = \varphi(\tau^*(a), x_0)$, $x_2 = \varphi(\tau(a), x_0)$. By (1.10) and (1.2) we have $x_1 = p_1 + q(a_1)$, $a_1 = h_1(a)$ and $x_2 = p + P(a)Z_0$. Hence, by (1.9) and (1.10) we have

$$\begin{aligned}&\varphi\big(\tau_1(a_1), x_1\big) = p_1 + q\big(P_1(a_1)\big),\\ &\varphi\big(\tau^*\big(P(a)\big), x_2\big) = p_1 + q(a_2), \quad a_2 = h_1\big(P(a)\big).\end{aligned}$$

On the other hand, by the flow property of φ we have

$$\begin{aligned}x_3 &= \varphi\big(\tau_1(a_1), x_1\big) = \varphi\big(\tau_1(a_1) + \tau^*(a), x_0\big) = \varphi\big(\tau^*\big(P(a)\big) + \tau(a), x_0\big)\\ &= \varphi\big(\tau^*\big(P(a)\big), x_2\big),\end{aligned}$$

which, together with the above, follows that $q(P_1(a_1)) = q(a_2)$ or $a_2 = P_1(a_1)$. Hence $h_1 \circ P = P_1 \circ h_1$.

It needs only to prove $h_1'(0) > 0$. Let $a \geqslant 0$. Introduce one more cross section below

$$l'\colon\ x = u(t_1) + Z(t_1)a, \quad 0 \leqslant a \leqslant \varepsilon.$$

Let $\tilde{\tau}_1(a) = t_1 + \mathrm{O}(a)$ be such that $\theta(\tilde{\tau}_1, a) = t_1$. By (1.3) we have

$$\overline{x}_1 = \varphi(\tilde{\tau}_1, x_0) = u(t_1) + Z(t_1)b(t_1, a) \in l'.$$

Then $b(t_1, a) = |p_1\overline{x}_1|$. By the proof of Lemma 1.3,

$$\frac{\partial b}{\partial a}(t_1, 0) = \exp\int_0^{t_1} A(s)\,\mathrm{d}s > 0.$$

Consider the triangle formed by points p_1, x_1 and $\overline{x}_1$. There exists a point x^* on the orbital arc $\widehat{x_1\overline{x}_1}$ such that $f(x^*)$ is parallel to the side $x_1\overline{x}_1$. Since the arc $\widehat{x_1\overline{x}_1}$ approaches p_1 as $a \to 0$ we have $x^* \to p_1$, $f(x^*) \to f(p_1)$ as $a \to 0$. Hence, if we let α_1 denote the angle between sides $p_1\overline{x}_1$ and $\overline{x}_1x_1$, and α_2 the angle between sides p_1x_1 and $\overline{x}_1x_1$, then we have $\alpha_1 \to \frac{\pi}{2}, \alpha_2 \to \alpha_0$ as $a \to 0$, where $\alpha_0 \in (0, \frac{\pi}{2}]$ is the angle between the vectors $f(p_1)$ and $q'(0)$. That is, α_0 is the angle between L and l_1 at p_1. By the Sine theorem, it follows

$$\frac{|p_1\overline{x}_1|}{\sin\alpha_2} = \frac{|p_1x_1|}{\sin\alpha_1}, \quad \text{or}$$

$$\bigl|q\bigl(h_1(a)\bigr)\bigr| = \frac{\sin\alpha_1}{\sin\alpha_2}b(t_1, a) = \frac{a}{\sin\alpha_0}\exp\int_0^{t_1} A(s)\,\mathrm{d}s\bigl(1 + \mathrm{O}(a)\bigr).$$

On the other hand, $q(h_1(a)) = q'(0)h_1'(0)a + \mathrm{O}(a^2)$ which gives

$$\bigl|q\bigl(h_1(a)\bigr)\bigr| = \bigl|q'(0)\bigr| \cdot \bigl|h_1'(0)\bigr|a + \mathrm{O}\bigl(a^2\bigr), \quad a > 0.$$

Hence, we obtain

$$\bigl|h_1'(0)\bigr| = \frac{1}{|q'(0)|\sin\alpha_0}\exp\int_0^{t_1} A(s)\,\mathrm{d}s \neq 0.$$

Noting that $h_1(a) > 0$ for $a > 0$ we have $h_1'(0) > 0$. The proof is completed. □

COROLLARY 1.1. *The stability and the multiplicity of the limit cycle L are independent of the choice of cross sections.*

PROOF. By Lemma 1.4 we have

$$h_1'(\overline{a})\bigl[P(a) - a\bigr] = P_1\bigl(h_1(a)\bigr) - h_1(a), \tag{1.11}$$

where $\overline{a}$ lies between a and $P(a)$. By (1.11) and Definition 1.3, the stability of L under P is the same as that of it under P_1. Also, if the limit cycle L has multiplicity k under P, then $P(a) - a = c_k a^k + \mathrm{O}(a^{k+1})$ for some $c_k \neq 0$. It follows from (1.11) that

$$P_1(a) - a = \overline{c}_k a^k + \mathrm{O}\big(a^{k+1}\big), \quad \overline{c}_k = \frac{c_k}{[h_1'(0)]^{k-1}}.$$

Therefore, L has the same multiplicity under P_1. This ends the proof. □

In the following we discuss the relation of equivalence between two planar systems. Consider (1.1) and another system of the form

$$\dot{y} = g(y), \tag{1.12}$$

where $g : D \to \mathbb{R}^2$ is C^r $(r \geqslant 1)$ on a region $D \subset \mathbb{R}^2$.

DEFINITION 1.5. Let $U \subset G$, $V \subset D$ be two regions. Two planar systems defined by vector fields $f|_U$ and $g|_V$ are said to be C^k $(1 \leqslant k \leqslant r)$ *equivalent* if there exists a C^k diffeomorphism $h : U \to V$ which takes orbits of (1.1) on U to orbits of (1.12) on V preserving their orientation.

Let $\psi(t, y)$ denote the flow generated by (1.12). Then under the condition of Definition 1.5 a C^k function $s(t, x)$ exists with $s(0, x) = 0$, $\frac{\partial s}{\partial t} > 0$ such that

$$h\big(\varphi(t, x)\big) = \psi\big(s(t, x), h(x)\big), \tag{1.13}$$

as long as $\varphi(t, x) \in U$.

If the functions f and g have the following relationship:

$$g\big(h(x)\big) = \mathrm{D}h(x) f(x),$$

then the system (1.12) is obtained from (1.1) by making the coordinate transformation $y = h(x)$. In this case, (1.13) becomes $h \circ \varphi^t = \psi^t \circ h$. If f and g satisfy $g(x) = K(x) f(x)$ where $K : \mathbb{R}^2 \to \mathbb{R}$ is a C^r positive function, then orbits of (1.1) and (1.12) are identical, and the flows φ and ψ satisfy

$$K\big(\varphi(t, x)\big)\frac{\mathrm{d}\varphi}{\mathrm{d}t} = g\big(\varphi(t, x)\big), \qquad \frac{\mathrm{d}\psi}{\mathrm{d}s} = g\big(\psi(s, x)\big).$$

Hence, we are to sink a function $s(t, x)$ with $s(0, x) = 0$ and satisfying

$$\varphi(t, x) = \psi\big(s(t, x), x\big).$$

Differentiating the equality in t gives

$$\frac{\mathrm{d}\varphi}{\mathrm{d}t} = \frac{\mathrm{d}\psi}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}t}.$$

Substituting the equality above into the previous equations yields

$$\frac{\mathrm{d}\psi}{\mathrm{d}s} = K\big(\varphi(t,x)\big)\frac{\mathrm{d}\varphi}{\mathrm{d}t} = K\big(\varphi(t,x)\big)\frac{\mathrm{d}\psi}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}t}.$$

Thus, the function s should satisfy $\frac{\mathrm{d}s}{\mathrm{d}t} = \frac{1}{K(\varphi(t,x))}$, which has the solution

$$s(t,x) = \int_0^t \frac{\mathrm{d}t}{K(\varphi(t,x))}.$$

With this choice of $s(t,x)$ above one can prove $\varphi(t,x) = \psi(s(t,x),x)$ by the uniqueness of initial solutions.

For C^k equivalent systems we have the following lemma.

LEMMA 1.5. *Suppose* (1.1) *and* (1.12) *are C^k equivalent under a C^k diffeomorphism $h: U \to V$, $1 \leqslant k \leqslant r$. Let $L \subset U$ and $L_1 = h(L) \subset V$ be limit cycles of* (1.1) *and* (1.12) *respectively. Then*:

(i) *The cycles L and L_1 have the same multiplicity.*

(ii) *The inner* (*outer*) *stability of L is the same as the inner* (*outer*) *stability of L_1 if $h((Int.L) \cap U) \subset Int.L_1$, and the inner* (*outer*) *stability of L is the same as the outer* (*inner*) *stability of L_1 if $h((Int.L) \cap U) \subset Ext.L_1$.*

PROOF. For the limit cycle L, take a cross section l at $p \in L$ as before. Then the curve $l_1 = h(l)$ is a cross section of L_1 at $p_1 = h(p)$. Let

$$Z_1 = \frac{1}{|g(p_1)|}\big(-g_2(p_1), g_1(p_1)\big)^{\mathrm{T}}, \quad Z_1' = h_x(p)Z_0.$$

Note that $h(p + aZ_0) = p_1 + Z_1'a + \mathrm{O}(a^2)$. It is easy to see that the vector Z_1' is tangent to l_1 at p_1. According to the orientation of L_1 and the direction of Z_1' there are four cases to consider as follows:

- Case 1. $Z_1 \cdot Z_1' > 0$ with L_1 clockwise oriented;
- Case 2. $Z_1 \cdot Z_1' < 0$ with L_1 clockwise oriented;
- Case 3. $Z_1 \cdot Z_1' > 0$ with L_1 counter clockwise oriented;
- Case 4. $Z_1 \cdot Z_1' < 0$ with L_1 counter clockwise oriented.

See Fig. 3.

By (1.13) the periods T of L and T_1 of L_1 have the relation $T_1 = s(T, p)$. Let P be the Poincaré map near L defined by (1.2). The cross section l_1 has a representation

$$y = h(p + aZ_0) = p_1 + q(a),$$

where $q(a) = h(p + aZ_0) - h(p) = Z_1'a + \mathrm{O}(a^2)$. Introduce a function q_1 as follows:

$$q_1(a) = \begin{cases} q(a) & \text{for case 1 or 3,} \\ q(-a) & \text{for case 2 or 4.} \end{cases}$$

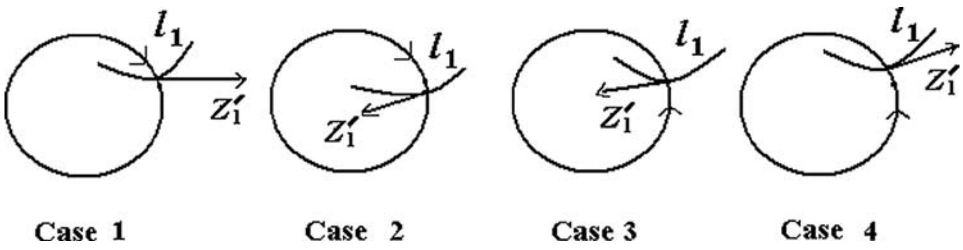

Fig. 3. Four possible cases for L_1 and Z_1'.

Then l_1 can be rewritten as l_1: $y = p_1 + q_1(a)$, $|a| \ll 1$ with q_1 satisfying $Z_1' \cdot q_1'(0) > 0$. On l_1 we can define a Poincaré map P_1 near L_1 by

$$\psi\big(\tau_1(a), p_1 + q_1(a)\big) = p_1 + q_1\big(P_1(a)\big) \in l_1, \tag{1.14}$$

where $\tau_1(a) = T_1 + \mathrm{O}(a)$ is the time of the first return to l_1.

Since $h(p + aZ_0) = p_1 + q(a) = p_1 + q_1((-1)^{i-1}a)$ for case i, we have

$$h\big(p + P(a)Z_0\big) = p_1 + q\big(P(a)\big) = p_1 + q_1\big((-1)^{i-1}P(a)\big) \in l_1$$

and hence by (1.2)

$$h\big(\varphi\big(\tau(a), p + aZ_0\big)\big) = p_1 + q_1\big((-1)^{i-1}P(a)\big) \in l_1. \tag{1.15}$$

On the other hand, by (1.13) we have

$$\begin{aligned} h\big(\varphi\big(\tau(a), p + aZ_0\big)\big) &= \psi\big(s\big(\tau(a), p + aZ_0\big), h(p + aZ_0)\big) \\ &= \psi\big(\tau^*(a), p_1 + q_1\big((-1)^{i-1}a\big)\big) \in l_1, \end{aligned} \tag{1.16}$$

for case i, where $\tau^*(a) = s(\tau(a), p + aZ_0) = T_1 + \mathrm{O}(a)$.

Hence, comparing (1.14) with (1.16) we obtain

$$\tau^*(a) = \tau_1\big((-1)^{i-1}a\big), \qquad h\big(\varphi\big(\tau(a), p + aZ_0\big)\big) = p_1 + q_1\big(P_1\big((-1)^{i-1}a\big)\big).$$

Therefore, it follows from (1.15) that $(-1)^{i-1}P(a) = P_1((-1)^{i-1}a)$ for case i. Thus for case i we have

$$a\big(P(a) - a\big) = (-1)^{i-1}a\big[P_1\big((-1)^{i-1}a\big) - (-1)^{i-1}a\big].$$

Hence, similar to Corollary 1.1, one can prove easily that L and L_1 have the same multiplicity. Furthermore, they have the same stability for cases 1 and 4. However, for cases 2 and 3, the inner (outer) stability of L is the same as the outer (inner) stability of L_1.

Then noting that $h((Int.L) \cap U) \subset Int.L_1$ for cases 1 and 4, and $h((Int.L) \cap U) \subset Ext.L_1$ for cases 2 and 3, the proof follows from Corollary 1.1. $\square$

EXAMPLE 1.3. Consider the system

$$\dot{x} = y, \qquad \dot{y} = -x + y\bigl(x^2 + y^2 - 1\bigr).$$

By Theorem 1.1, the system has a unique limit cycle L: $x^2 + y^2 = 1$, and it is hyperbolic and unstable.

Define four functions

$$h_1(x, y) = (x, y)^{\mathrm{T}}, \quad h_2(x, y) = \left(\frac{x}{x^2 + y^2}, \frac{y}{x^2 + y^2}\right)^{\mathrm{T}},$$
$$h_3(x, y) = \left(\frac{y}{x^2 + y^2}, \frac{x}{x^2 + y^2}\right)^{\mathrm{T}}, \quad h_4(x, y) = (y, x)^{\mathrm{T}},$$

and a region $U = \{(x, y)\colon x^2 + y^2 > \frac{1}{2}\}$.

Let

$$\dot{u} = g_{i1}(u, v), \qquad \dot{v} = g_{i2}(u, v)$$

denote the system obtained from the previous cubic system by making the coordinate transformation $(u, v)^{\mathrm{T}} = h_i(x, y)$, $(x, y) \in U$. Note that the unit circle is invariant under each h_i. It is evident that the case i in Fig. 3 occurs with $L_1 = L$ for each $i \in \{1, 2, 3, 4\}$.

This example shows that each case in Fig. 3 can happen. In particular, the orientation of a limit cycle may be changed under a coordinate transformation.

1.3. *Perturbations of a limit cycle*

In the rest, we return to the perturbations of a limit cycle.

Consider the following system

$$\dot{x} = f(x) + F(x, \mu) \tag{1.17}$$

where $\mu \in \mathbb{R}^m$ is a vector parameter with $m \geqslant 1$, and $F : G \times \mathbb{R}^m \to \mathbb{R}^2$ is a C^r function with $F(x, 0) = 0$. Thus, system (1.1) is the unperturbed system of (1.17). As before, let (1.1) have a limit cycle L: $x = u(t)$, $0 \leqslant t \leqslant T$. Then completely similar to Lemma 1.2 we have the following lemma.

LEMMA 1.6. *The transformation* (1.3) *carries* (1.17) *into the system*

$$\begin{aligned} \dot{\theta} &= 1 + g_1(\theta, b) + h(\theta, b)F\bigl(u(\theta) + Z(\theta)b, \mu\bigr), \\ \dot{b} &= A(\theta)b + g_2(\theta, b) + Z^{\mathrm{T}}(\theta)F\bigl(u(\theta) + Z(\theta)b, \mu\bigr), \end{aligned} \tag{1.18}$$

where the functions A, g_1, g_2 and h are the same as those given in Lemma 1.2.

By (1.18) we have

$$\frac{\mathrm{d}b}{\mathrm{d}\theta} = R(\theta, b, \mu), \tag{1.19}$$

where $R(\theta, b, \mu) = A(\theta)b + Z^{\mathrm{T}}(\theta)F_\mu(u(\theta), 0)\mu + \mathrm{O}(|b, \mu|^2)$.

Let $b(0, a, \mu)$ denote the solution of (1.19) with $b(0, a, \mu) = a$. We can write

$$b(\theta, a, \mu) = b_1(\theta)a + b_0(\theta)\mu + \mathrm{O}\big(|a, \mu|^2\big),$$

where $b_1(0) = 1$, $b_0(0) = 0$. Inserting the above into (1.19) yields

$$b_1' = Ab_1, \quad b_0' = Ab_0 + Z^{\mathrm{T}}F_\mu\big(u(s), 0\big).$$

It follows that $b_1(\theta) = \exp\int_0^\theta A(s)\,\mathrm{d}s$ as before, and

$$b_0(\theta) = b_1(\theta)\int_0^{\mathrm{T}} b_1^{-1}(s)Z^{\mathrm{T}}(s)F_\mu\big(u(s), 0\big)\,\mathrm{d}s.$$

Therefore,

$$\begin{aligned} b(T, a, \mu) = \exp\int_0^{\mathrm{T}} A(s)\,\mathrm{d}s\left[a + \int_0^{\mathrm{T}} b_1^{-1}(s)Z^{\mathrm{T}}(s)F_\mu\big(u(s), 0\big)\,\mathrm{d}s\mu\right] \\ + \mathrm{O}\big(|a, \mu|^2\big). \end{aligned} \tag{1.20}$$

On the other hand, using (1.2) we can define a Poincaré map $P(a, \mu)$ similarly. By Lemma 1.3 it follows

$$P(a, \mu) = b(T, a, \mu). \tag{1.21}$$

Obviously, for $|\mu|$ small (1.17) has a limit cycle near L_1 if and only if P has a fixed point in a near $a = 0$.

The simplest case is that L is hyperbolic. In this case, L will persist under perturbations. In other words, we have:

THEOREM 1.2. *Let L be hyperbolic. Then there exist $\varepsilon > 0$ and a neighborhood U of L such that* (1.17) *has a unique limit cycle in U for $|\mu| < \varepsilon$. Moreover, the limit cycle is also hyperbolic and has the same stability as L.*

PROOF. Since L is hyperbolic we have $P_a'(0, 0) \neq 1$, or equivalently $I(L) = \oint_L \operatorname{div} f\,\mathrm{d}t \neq 0$. By (1.20) and (1.21),

$$P(a, \mu) - a = \big(\mathrm{e}^{I(L)} - a\big)a + N_0\mu + \mathrm{O}\big(|a, \mu|^2\big), \tag{1.22}$$

where $N_0 = \mathrm{e}^{I(L)}\int_0^{\mathrm{T}} \exp(-\int_0^t A(s)\,\mathrm{d}s)Z^{\mathrm{T}}(s)F_\mu(u(s), 0)\,\mathrm{d}s$.

For (a,μ) near zero applying the implicit function theorem to the equation $P(a,\mu)-a=0$ we find a unique fixed point $a=a^*(\mu)=\mathrm{O}(\mu)$ of P. This means that for $|\mu|$ small (1.17) has a unique limit cycle, denoted by L_μ, near L. The cycle has a representation $\varphi(t,p+a^*(\mu)Z_0,\mu)$ where $\varphi(t,x,\mu)$ denotes the flow of (1.17) with $\varphi(0,x,\mu)=x$. Moreover, by (1.22) we have $P'_a(a^*(\mu),\mu)=\mathrm{e}^{I(L)}+\mathrm{O}(|a^*(\mu),\mu|)$, which gives

$$\big(\mathrm{e}^{I(L)}-1\big)\big[P'_a\big(a^*(\mu),\mu\big)-1\big]>0$$

for all $|\mu|$ small. Then the conclusion follows from Theorem 1.1. This ends the proof. □

Further, for the nonhyperbolic case we have

THEOREM 1.3. *Let L be a nonhyperbolic limit cycle of the C^r system* (1.1) *with $r\geqslant 2$.*

(i) *If L has multiplicity* 2, *then there exist $\varepsilon>0$, a neighborhood U of L and a C^r function $\Delta(\mu)=\mathrm{O}(\mu)$ such that* (1.17) *has no limit cycles* (*respectively a limit cycle of multiplicity* 2, *two hyperbolic limit cycles*) *in U as $\Delta(\mu)<0$* (*respectively* $=0$, >0) *for $|\mu|<\varepsilon$.*

(ii) *If L has multiplicity k with $3\leqslant k\leqslant r$, then there exist $\varepsilon>0$ and a neighborhood U of L such that* (1.17) *has at most k limit cycles in U for $|\mu|<\varepsilon$. Moreover,* (1.17) *has at least a limit cycle in U for $|\mu|<\varepsilon$ if k is odd.*

PROOF. Since $r\geqslant 2$, $I(L)=0$ and L has multiplicity 2 we can rewrite (1.22) as

$$P(a,\mu)-a=Q_0(\mu)+Q_1(\mu)a+Q_2(\mu)a^2\big(1+\mathrm{o}(1)\big),$$

where $Q_0(0)=Q_1(0)=0$, $Q_2(0)\neq 0$.

Let $G(a,\mu)=P(a,\mu)-a$, which is called a bifurcation function of (1.17). By the implicit function theorem a unique C^r function $q(\mu)=\mathrm{O}(\mu)$ exists such that $G_a(q(\mu),\mu)=0$ for $|\mu|$ small. Then Taylor's formula yields

$$G(a,\mu)=G\big(q(\mu),\mu\big)+\frac{1}{2}G_{aa}\big(q(\mu),\mu\big)\big(a-q(\mu)\big)^2\big(1+\mathrm{o}(1)\big).$$

Now it is clear that the conclusion (i) follows by taking $\Delta(\mu)=-G(q(\mu),\mu)Q_2(0)$.

To prove the second conclusion let us assume (1.17) has $k+1$ limit cycles in an arbitrary neighborhood of L for some sufficiently small $\mu\neq 0$. Then the function G has $k+1$ zero in a for this small μ. From Rolle's theorem, $\frac{\partial G}{\partial a}$ has k zeros in a. Using the same theorem repeatedly we see that $\frac{\partial^k G}{\partial a^k}$ has a zero $a_0(\mu)$ which can be arbitrarily small as μ goes to zero.

On the other hand, we have

$$\frac{\partial^k G}{\partial a^k}=\frac{\partial^k P}{\partial a^k},\qquad P(a,0)-a=q_k a^k+\mathrm{o}\big(a^k\big),\quad q_k\neq 0,$$

which implies $\frac{\partial^k G}{\partial a^k}=k!q_k+\mathrm{o}(1)\neq 0$ for (a,μ) near zero. This is a contradiction. Hence, (1.17) has at most k limit cycles near L for $|\mu|$ small.

Finally, if k is odd, we have then $q_k a[P(a,0) - a] > 0$ for $|a| = \varepsilon$, where $\varepsilon > 0$ is a small constant. Thus, there exists a constant $\delta > 0$ such that $q_k a[P(a,\mu) - a] > 0$ for $|a| = \varepsilon$, $|\mu| \leqslant \delta$. Therefore, a function $a^*(\mu)$ exists with $|a^*(\mu)| < \varepsilon$ such that $P(a^*(\mu),\mu) - a^*(\mu) = 0$, $|\mu| < \delta$. The proof is completed. $\square$

EXAMPLE 1.4. Consider

$$\begin{aligned}\dot{x} &= -y + x\big(x^2+y^2-1\big)^2 - x\big[\mu_1\big(x^2+y^2\big)+\mu_2\big],\\ \dot{y} &= x + y\big(x^2+y^2-1\big)^2 - y\big[\mu_1\big(x^2+y^2\big)+\mu_2\big].\end{aligned} \tag{1.23}$$

For $\mu_1 = \mu_2 = 0$, (1.23) has a unique limit cycle

$$L: \quad x = \cos t, \quad y = \sin t, \quad 0 \leqslant t \leqslant 2\pi.$$

Similar to Example 1.2, the limit cycle L has multiplicity 2 with $P_a''(0,0) = -16\pi$. We make a transformation of the form $(x,y) = (1-b)(\cos\theta, \sin\theta)$, $0 \leqslant \theta \leqslant 2\pi$, so that (1.23) becomes

$$\dot{\theta} = 1, \qquad \dot{b} = -(1-b)\big[h^2 - \mu_1 h - (\mu_1+\mu_2)\big],$$

where $h = (1-b)^2 - 1$. Hence we have

$$\frac{\mathrm{d}b}{\mathrm{d}\theta} = -(1-b)\big[h^2 - \mu_1 h - (\mu_1+\mu_2)\big].$$

Obviously, the solution $b(\theta, a, \mu_1, \mu_2)$ of the above equation with $b(0, a, \mu_1, \mu_2) = a$ is 2π-periodic near $b = 0$ if and only if the initial data a satisfies

$$G^*(a, \mu_1, \mu_2) \equiv a^2 - \mu_1 a - (\mu_1+\mu_2) = 0.$$

Let $\Delta(\mu_1,\mu_2) = \mu_1^2 + 4(\mu_1+\mu_2)$. Then for (μ_1,μ_2) near $(0,0)$, (1.23) has no limit cycles (respectively a unique multiple 2 limit cycle, two hyperbolic limit cycles) if $\Delta(\mu_1,\mu_2) < 0$ (respectively $= 0$, > 0). The equation $\Delta(\mu_1,\mu_2) = 0$ defines a curve $\mu_2 = -\mu_1 - \frac{1}{4}\mu_1^2$ on the (μ_1,μ_2)-plane, which is called a bifurcation curve of saddle-node type. See Fig. 4.

Turn back to system (1.17). Note that

$$A(\theta) = \operatorname{tr} f_x(u) - \frac{\mathrm{d}}{\mathrm{d}\theta}\ln\big|f(u)\big|, \qquad Z(\theta) = \frac{1}{|f(u)|}\big(-f_2(u), f_1(u)\big).$$

The constant N_0 in (1.22) can be written as $N_0 = \frac{1}{|f(u(0))|}\mathrm{e}^{I(L)}M$, where

$$M = \int_0^{\mathrm{T}} \mathrm{e}^{-\int_0^t \operatorname{tr} f_x(u(s))\,\mathrm{d}s} f\big(u(t)\big) \wedge F_\mu\big(u(t),0\big)\,\mathrm{d}t, \tag{1.24}$$

with $(a_1,a_2) \wedge (b_1,b_2) = a_1b_2 - a_2b_1$, $\mu \in \mathbb{R}$.

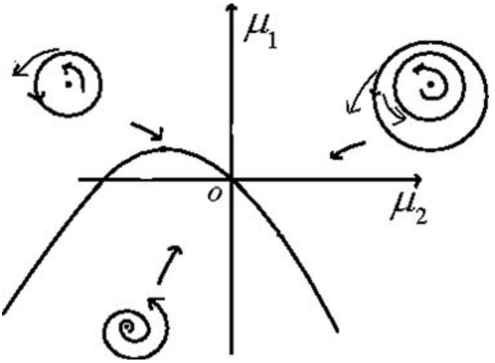

Fig. 4. Bifurcation diagram (saddle-node type) for (1.23).

Thus, if $P(a,0)-a=q_k a^k+\mathrm{o}(a^k)$, we can rewrite (1.22) as

$$G(a,\mu)=P(a,\mu)-a=q_k a^k+\frac{\mathrm{e}^{I(L)}}{|f(u(0))|}M\mu+\mathrm{o}\big(\big|\mu,a^k\big|\big). \tag{1.25}$$

Using (1.25) we can prove

THEOREM 1.4. *Let* (1.17) *be analytic with* $\mu\in\mathbb{R}$. *If* $M\neq 0$, *then exist* $\varepsilon>0$ *and a neighborhood* U *of* L *such that for* $|\mu|<\varepsilon$ *and in the region* U, (1.17) *has*

(i) *a unique limit cycle with multiplicity one if* L *is of odd multiplicity*;
(ii) *two limit cycles with each having multiplicity one for* μ *lying one side of* $\mu=0$ *and no limit cycles for* μ *lying the opposite side if* L *is of even multiplicity*;
(iii) *no limit cycles if* L *is nonisolated.*

PROOF. By Theorem 1.2 we may suppose $I(L)=0$. By (1.25), a unique function of the form

$$\mu=-\frac{q_k}{M}\big|f\big(u(0)\big)\big|a^k+\mathrm{O}\big(a^{k+1}\big)=\mu^*(a) \tag{1.26}$$

exists such that $G(a,\mu^*(a))=0$. If k is odd with $q_k\neq 0$ the function μ^* has a unique inverse

$$a=\left(\frac{-M\mu}{q_k|f(u(0))|}\right)^{1/k}\big(1+\mathrm{o}\big(\mu^{1/k}\big)\big)=a^*(\mu),$$

which satisfies $\frac{\partial G}{\partial a}(a^*(\mu),\mu)\neq 0$.

Then the conclusion (i) follows. The conclusion (ii) follows just similarly.

In the case that L is a nonisolated periodic orbit, we have $G(a,0)\equiv 0$ for $|a|$ small. This implies that $\mu^*(a)\equiv 0$ since $G(a,\mu)=0$ if and only if $\mu=\mu^*(a)$. Hence, for all $|\mu|>0$ we have $G(a,\mu)\neq 0$. This means that (1.17) has no limit cycles near L for $|\mu|>0$ small. This ends the proof. □

EXAMPLE 1.5. Consider (1.23) again with (μ_1, μ_2) varying on a straight line. That is, let $\mu_1 = \mu$, $\mu_2 = c\mu$, where c is a constant. Then (1.23) becomes

$$\begin{aligned} \dot{x} &= -y + x\bigl(x^2 + y^2 - 1\bigr)^2 - \mu x\bigl(x^2 + y^2 + c\bigr), \\ \dot{y} &= x + y\bigl(x^2 + y^2 - 1\bigr)^2 - \mu y\bigl(x^2 + y^2 + c\bigr). \end{aligned} \tag{1.27}$$

By (1.24) we have $M = (1 + c)2\pi$. Note that $q_2 = \frac{1}{2}P_a''(0, 0) = -8\pi$. The formula (1.26) becomes $\mu^*(a) = \frac{4}{1+c}a^2 + O(a^3)$, which has inverse functions

$$a = a_j(\mu) = \left[\frac{1+c}{4}\mu\right]^{1/2}\bigl[(-1)^j + O\bigl(|\mu|^{1/2}\bigr)\bigr], \quad j = 1, 2.$$

Thus, when $1 + c \neq 0$, (1.27) has no limit cycles (2 limit cycles) for $(1 + c)\mu < 0$ (> 0). When $(1 + c) = 0$, then (1.27) has always two limit cycles given by $x^2 + y^2 = 1$ and $x^2 + y^2 = 1 - \mu$ for all $|\mu| > 0$ small. This shows that the condition $M \neq 0$ in Theorem 1.4 is somehow necessary.

One can give the bifurcation diagram of (1.27) and compare it with Fig. 4.

REMARK 1.2. A typical result on qualitative theory of differential equations is the so-called Poincaré–Bendixson theorem which says that the positive limit set of a bounded positive semi-orbit is a connected curve consisting of singular points and orbits connecting them. One can find a proof of the theorem in Hale [35], Chicone [14] and Zhang et al. [127]. An important corollary of the theorem is that for an analytic system a positively invariant set with no singular points contains at least one limit cycle. This corollary has many applications to various planar systems to study the existence of a limit cycle. On the other hand, there are also many results on the nonexistence of a limit cycle or the existence of two or more limit cycles. The reader can consult Zhang et al. [127], Ye [116], Ye et al. [117] and Luo et al. [101] for a general theory of limit cycles. For a given planar system with or without parameters it is usually very significant and also difficult to find the number of limit cycles of it. Thousands of papers have been published on this aspect. For recent works, one can see [1,6,8,11,15,18,19,22–26,28–34,97–99].

Results in Theorems 1.1–1.4 are fundamental which can be found in Andronov [2], Chow and Hale [16] and Han [51]. The conclusions in Lemma 1.5 seem very natural, but not obvious. The proof presented here is new.

2. Focus values and Hopf bifurcation

2.1. *Poincaré map and focus value*

In this section we consider local behavior of a planar C^∞ systems near an elementary focus.

After removing the focus to the origin, the system can be written as

$$\begin{aligned}\dot{x} &= ax + by + F(x, y) = f(x, y),\\ \dot{y} &= cx + dy + G(x, y) = g(x, y),\end{aligned} \tag{2.1}$$

where $c \neq 0$, F and $G : \mathbb{R}^2 \to \mathbb{R}$ are C^∞ functions with

$$F(0,0) = G(0,0) = 0, \qquad \frac{\partial(F,G)}{\partial(x,y)}(0,0) = 0,$$

and the eigenpolynomial $h(\lambda) = \lambda^2 - (a+d)\lambda + ad - bc$ has a pair of conjugate complex zero $\alpha \pm \mathrm{i}\beta \neq 0$.

Let

$$C = \begin{pmatrix} 1 & \dfrac{\alpha - a}{\beta} \\ 0 & -\dfrac{c}{\beta} \end{pmatrix}, \qquad C^{-1} = \begin{pmatrix} 1 & \dfrac{\alpha - a}{c} \\ 0 & -\dfrac{\beta}{c} \end{pmatrix}.$$

By using $h(\alpha \pm \mathrm{i}\beta) = 0$, or

$$\alpha^2 - \beta^2 - (a+d)\alpha + ad - bc = 0, \qquad \big(2\alpha - (a+d)\big)\beta = 0,$$

it is easy to see that

$$\begin{aligned} &C^{-1}\begin{pmatrix} a & b \\ c & d \end{pmatrix} C = \begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix},\\ &\alpha = \frac{1}{2}(a+d), \quad |\beta| = \frac{1}{2}\sqrt{-4bc - (a-d)^2}. \end{aligned} \tag{2.2}$$

Then the linear transformation $(x, y)^{\mathrm{T}} = C(u, v)^{\mathrm{T}}$ carries (2.1) into the form

$$\dot{u} = \alpha u + \beta v + \widetilde{F}(u, v), \qquad \dot{v} = -\beta u + \alpha v + \widetilde{G}(u, v),$$

where $\widetilde{F}, \widetilde{G} = \mathrm{O}(|u, v|^2)$. We call the above system a first order normal form of (2.1).

Let us define a Poincaré map of (2.1) near the origin. For any given $\theta_0 \in [0, 2\pi)$, let

$$Z_0 = (\cos\theta_0, \sin\theta_0)^{\mathrm{T}}, \qquad Z_0^{\perp} = (\sin\theta_0, -\cos\theta_0)^{\mathrm{T}}.$$

The unit vector Z_0 determines a cross section l below

$$l: \quad (x, y)^{\mathrm{T}} = rZ_0, \quad 0 < r < r_0$$

for $r_0 > 0$ small. For $(x_0, y_0)^{\mathrm{T}} = rZ_0 \in l$, let $(x(t, x_0, y_0), y(t, x_0, y_0))$ be the solution of (2.1) with $x(0, x_0, y_0) = x_0$, $y(0, x_0, y_0) = y_0$. Then the formula of constant variation follows:

$$\begin{pmatrix} x(t, x_0, y_0) \\ y(t, x_0, y_0) \end{pmatrix} = \left[\exp\begin{pmatrix} at & bt \\ ct & dt \end{pmatrix}\right]\begin{pmatrix} x_0 \\ y_0 \end{pmatrix} + \mathrm{O}\big(|x_0, y_0|^2\big). \tag{2.3}$$

Thus,

$$\begin{pmatrix} x(t, x_0, y_0) \\ y(t, x_0, y_0) \end{pmatrix} - \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} = \left[\exp\begin{pmatrix} at & bt \\ ct & dt \end{pmatrix} - I\right] Z_0 r + \mathrm{O}\big(r^2\big) \equiv rV(t, r).$$

By (2.2) we have

$$V(t, r) = C\left[\exp\begin{pmatrix} \alpha t & \beta t \\ -\beta t & \alpha t \end{pmatrix} - I\right] C^{-1} Z_0 + \mathrm{O}(r).$$

Let $H(t, r) = [V(t, r)]^{\mathrm{T}} Z_0^{\perp}$. Define

$$V(t, 0) = \lim_{r \to 0} V(t, r) = C\left[\exp\begin{pmatrix} \alpha t & \beta t \\ -\beta t & \alpha t \end{pmatrix} - I\right] C^{-1} Z_0.$$

Also, if we allow the variable r to be negative in the definition of l then H is well defined for $|r| < r_0$. It is easy to see that

$$H(T, 0) = \big(\mathrm{e}^{\alpha T} - 1\big) Z_0 Z_0^{\perp} = 0, \qquad H_t(T, 0) = \mathrm{e}^{\alpha T} \beta \neq 0,$$

where $T = \frac{2\pi}{|\beta|}$. Hence, the implicit function theorem yields that a unique C^∞ function $\tau(r) = T + \mathrm{O}(r)$ exists such that $H(\tau(r), r) = 0$ for $|r| < r_0$. That is to say, for $0 < r < r_0$, $\tau(r)$ is the time of the first return to l by a circle. Therefore, we can write

$$\begin{pmatrix} x(\tau, x_0, y_0) \\ y(\tau, x_0, y_0) \end{pmatrix} = P(r) Z_0 \in l, \quad 0 < r < r_0, \tag{2.4}$$

where $P \in C^\infty$ for $|r| < r_0$ with $rP(r) > 0$ for $r \neq 0$.

DEFINITION 2.1. Let (2.1) satisfy (2.2). The function P defined by (2.4) is called a *Poincaré map* of (2.1) near the origin. The map is often written as $P : l \to l$.

DEFINITION 2.2. If there exists $r_0' > 0$ such that $P(r) - r < 0 (> 0)$ for $0 < r < r_0'$, we say the origin is a *stable* (*unstable*) *focus*. If $P(r) - r = 0$ for $0 < r < r_0'$, we say the origin is a *center*.

REMARK 2.1. Similar to Corollary 1.1 we can prove that the stability of the origin is independent of the choice of θ_0 which is the angle defining the section l.

In fact, for any given $\theta_0, \theta_1 \in [0, 2\pi)$ with $\theta_0 \neq \theta_1$, let the corresponding cross sections and Poincaré maps be l_0, l_1 and $P_0 : l_0 \to l_0$ and $P_1 : l_1 \to l_1$, respectively. Similarly, there exist unique C^∞ functions $\tau^*(r) = t_1 + \mathrm{O}(r)$ and $h_1(r) = \mathrm{O}(r)$ such that

$$\begin{pmatrix} x(\tau^*, rZ_0) \\ y(\tau^*, rZ_0) \end{pmatrix} = h_1(r) Z_1, \quad t_1 \in (0, T).$$

Differentiating the equation above in r and using formula of constant variation (2.3) we obtain

$$\left[\exp\begin{pmatrix} at_1 & bt_1 \\ ct_1 & dt_1 \end{pmatrix}\right] Z_0 = h_1'(0) Z_1,$$

which yields $h_1'(0) \neq 0$. It is clear that $h_1(r) > 0$ for $r > 0$. Thus, $h_1'(0) > 0$. Then in the same way as in Lemma 1.4 we have

$$h_1 \circ P_0 = P_1 \circ h_1,$$

which gives the conclusion in Remark 2.1 easily.

LEMMA 2.1. *For any given* $\theta_0 \in [0, 2\pi)$ *the origin is a stable* (*unstable*) *focus of* (2.1) *if and only if*

$$r\big[P(r) - r\big] < 0 \ (> 0) \quad \text{for } 0 < |r| < r_0.$$

Hence, if for some $k \geqslant 1$ *it holds that*

$$P(r) - r = 2\pi v_k r^k + \mathrm{O}\big(r^{k+1}\big), \quad v_k \neq 0, \tag{2.5}$$

then k is odd, and the origin is stable (*unstable*) *if* $v_k < 0$ (> 0).

PROOF. Let P_0 denote the function P defined by (2.4). For any $\theta \in [0, 2\pi)$ there exists a unique $\theta_1 \in [0, 2\pi)$ such that

$$\theta_1 = \theta_0 + \pi \quad \text{if } 0 \leqslant \theta_0 < \pi; \qquad \theta_0 = \theta_1 + \pi \quad \text{if } \pi \leqslant \theta_0 < 2\pi.$$

Let P_1 denote the Poincaré map associated to θ_1. We claim that

$$P_0(r) = -P_1(-r), \quad |r| < r_0. \tag{2.6}$$

For definiteness, assume $0 \leqslant \theta_0 < \pi$ and $0 < r < r_0$. Let $Z_1 = (\cos\theta_1, \sin\theta_1)$. Then $Z_1 = -Z_0$ and $(x_0, y_0)^{\mathrm{T}} = rZ_0 = (-r)Z_1$. Hence, by (2.4) we have

$$\begin{pmatrix} x(\tau, x_0, y_0) \\ y(\tau, x_0, y_0) \end{pmatrix} = P_0(r) Z_0 = P_1(-r) Z_1,$$

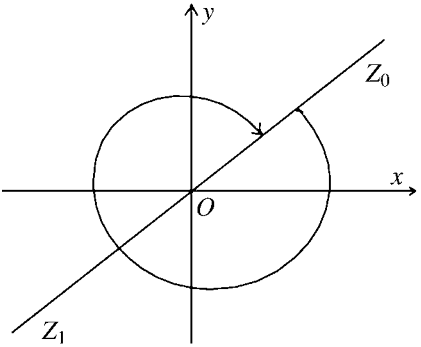

Fig. 5. The Poincaré maps P_0 and $P_1 (b > 0)$.

which gives (2.6). See Fig. 5.

By Definition 2.2, the origin is stable if and only if

$$P_0(r) - r < 0 \quad \text{for } 0 < r < r_0. \tag{2.7}$$

By Remark 2.1, the above inequality is equivalent to

$$P_1(r) - r < 0 \quad \text{for } 0 < r < r_0.$$

Note that by (2.6)

$$P_1(r) - r = -\big[P_0(-r) - (-r)\big].$$

Hence, (2.7) is equivalent to

$$P_0(r) - r > 0 \quad \text{for } 0 < -r < r_0.$$

Then combining (2.7) and the above together we see that (2.7) holds if and only if

$$r\big[P_0(r) - r\big] < 0 \quad \text{for } 0 < |r| < r_0.$$

Thus, if (2.5) holds, the number k must be odd and the sign of v_k determines the stability of the origin. This ends the proof. □

DEFINITION 2.3. Let (2.5) hold with $k = 2m + 1$, $m \geqslant 0$. We call the origin to be *a focus of order m*, and v_k the *mth Lyapunov constant* or *focus value*. The focus at the origin is called *rough or hyperbolic* (*weak or fine*) as $m = 0$ ($m \geqslant 1$).

REMARK 2.2. Similar to Remark 2.1 and Corollary 1.1, one can prove that the order and the first nonzero Lyapunov constant of the origin are independent of the choice of θ_0 and l.

For the sake of convenience, we will take $\theta_0 = 0$ below. In this case we have $(x_0, y_0) = (r, 0)$, and hence from (2.4) and (2.2)–(2.3) we obtain

$$\begin{aligned} P(r) &= \big(x(\tau, x_0, y_0), y(\tau, x_0, y_0)\big) Z_0 \\ &= \left[C \mathrm{e}^{\alpha\tau} \begin{pmatrix} \cos\beta\tau & \sin\beta\tau \\ -\sin\beta\tau & \cos\beta\tau \end{pmatrix} C^{-1} \begin{pmatrix} r \\ 0 \end{pmatrix} + \mathrm{O}\big(r^2\big) \right]^{\mathrm{T}} Z_0, \end{aligned}$$

which yields $P(r) = r\mathrm{e}^{\alpha T} + \mathrm{O}(r^2)$ since $\tau(0) = T$. Comparing with (2.5) gives that

$$v_1 = \frac{1}{2\pi}\big[\mathrm{e}^{\alpha T} - 1\big] = \frac{1}{2\pi}\big[\mathrm{e}^{\frac{a+d}{2}T} - 1\big].$$

Thus, the origin is stable (unstable) if

$$\operatorname{div}(f, g)|_0 = f_x(0, 0) + g_y(0, 0) < 0 \ (> 0).$$

Next, we suppose $\alpha = 0$ and give a computation formula for v_3. For the purpose it is convenient to use the first order normal form of (2.1). Without loss of generality we may suppose (2.1) has been of the form. In other words, we may assume (2.2) holds with C being the identity. Introducing the polar coordinate to (2.1) we obtain

$$\dot{r} = \cos\theta F + \sin\theta G, \qquad \dot{\theta} = -b + (\cos\theta G - \sin\theta F)/r \tag{2.8}$$

and

$$\frac{\mathrm{d}r}{\mathrm{d}\theta} = \frac{\cos\theta F + \sin\theta F}{-b + (\cos\theta G - \sin\theta F)/r} \equiv R(\theta, r). \tag{2.9}$$

Let $r(\theta, r_0)$ be the solution of (2.9) with $r(0, r_0) = r_0$. We have

LEMMA 2.2. *Let $a = d = 0, b = -c \neq 0$. Then*

(i) $P(r_0) = r(2\pi, r_0)$ *if* $b < 0$, *and* $P(r(2\pi, r_0)) = r_0$ *if* $b > 0$,

(ii) $v_3 = \frac{1}{2\pi}\operatorname{sgn}(-b)\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta$, *where* $R_3(\theta) = \frac{1}{3!}\frac{\partial^3 R}{\partial r^3}(\theta, 0)$.

PROOF. The conclusion (i) can be proved in a similar manner to Lemma 1.3. Let

$$R(\theta, r) = R_2(\theta)r^2 + R_3(\theta)r^3 + \cdots \tag{2.10}$$

and

$$r(\theta, r_0) = r_1(\theta)r_0 + r_2(\theta)r_0^2 + r_3(\theta)r_0^3 + \cdots,$$

where $r_1(0) = 1, r_2(0) = r_3(0) = 0$. Inserting the above solution and (2.10) into (2.9), and then comparing the like powers of r_0 we obtain

$$r_1'(\theta) = 0, \qquad r_2'(\theta) = R_2 r_1^2, \qquad r_3'(\theta) = R_3 r_1^2 + 2R_2 r_1 r_2,$$

or

$$r_1(\theta) = 1, \qquad r_2(\theta) = \int_0^\theta R_2(\theta)\,\mathrm{d}\theta,$$
$$r_3(\theta) = \int_0^\theta \big[R_3(\theta) + 2R_2(\theta)r_2(\theta)\big]\,\mathrm{d}\theta.$$

Hence, if we let

$$\widetilde{P}(r_0) = r(2\pi, r_0) = r_0 + 2\pi\,\tilde{v}_2 r_0^2 + 2\pi\,\tilde{v}_3 r_0^3 + \mathrm{O}\big(r_0^4\big),$$

then

$$\begin{aligned}\tilde{v}_2 &= \frac{1}{2\pi}\int_0^{2\pi} R_2(\theta)\,\mathrm{d}\theta,\\ \tilde{v}_3 &= \frac{1}{2\pi}\int_0^{2\pi}\big[R_3(\theta) + 2R_2(\theta)r_2(\theta)\big]\,\mathrm{d}\theta\\ &= \frac{1}{2\pi}\bigg[\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta + \int_0^{2\pi} 2r_2(\theta)r_2'(\theta)\,\mathrm{d}\theta\bigg]\\ &= \frac{1}{2\pi}\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta + 2\pi(\tilde{v}_2)^2.\end{aligned}$$

If $b < 0$, we have $P(r_0) = \widetilde{P}(r_0)$, and by Lemma 2.1, $\tilde{v}_2 = 0$. Thus

$$v_3 = \tilde{v}_3 = \frac{1}{2\pi}\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta.$$

If $b > 0$, we have $P(r_0) = \widetilde{P}^{-1}(r_0)$. Note that if $\widetilde{P}(r_0) = r_0 + 2\pi\,\tilde{v}_k r_0^k + \mathrm{O}(r_0^{k+1})$ then

$$\widetilde{P}^{-1}(r_0) = r_0 - 2\pi\,\tilde{v}_k r_0^k + \mathrm{O}\big(r_0^{k+1}\big).$$

Hence, using Lemma 2.1 we have $\tilde{v}_2 = 0$ and

$$v_3 = -\tilde{v}_3 = -\frac{1}{2\pi}\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta.$$

This ends the proof. □

Based on the above lemma we can prove:

THEOREM 2.1. *Let* $a = d = 0, b = -c \neq 0$, *and*

$$F(x,y) = \sum_{i+j=2}^{3} a_{ij}x^i y^j + \mathrm{o}\big(|x,y|^3\big),$$

$$G(x,y) = \sum_{i+j=2}^{3} b_{ij}x^i y^j + \mathrm{o}\big(|x,y|^3\big).$$

Then

$$\begin{aligned} v_3 &= \frac{1}{8|b|}\bigg\{3(a_{30}+b_{03}) + a_{12} + b_{21} - \frac{1}{b}\big[a_{11}(a_{20}+a_{02}) - b_{11}(b_{20}+b_{02}) \\ &\quad + 2(a_{02}b_{02} - a_{20}b_{20})\big]\bigg\} \\ &= \frac{1}{16|b|}\bigg\{F_{xxx} + F_{xyy} + G_{yyy} - \frac{1}{b}\big[F_{xy}(F_{xx}+F_{yy}) - G_{xy}(G_{xx}+G_{yy}) \\ &\quad - F_{xx}G_{xx} + F_{yy}G_{yy}\big]\bigg\}\bigg|_{(0,0)}. \end{aligned}$$

PROOF. By (2.9) and (2.10),

$$R_2(\theta) = -b^{-1}P_2(\theta), \qquad R_3(\theta) = -b^{-1}\big[P_3(\theta) + b^{-1}P_2(\theta)S_2(\theta)\big],$$

where

$$\begin{aligned} &P_k(\theta) = \cos\theta F_k(\cos\theta,\sin\theta) + \sin\theta G_k(\cos\theta,\sin\theta), \\ &S_k(\theta) = \cos\theta G_k(\cos\theta,\sin\theta) - \sin\theta F_k(\cos\theta,\sin\theta), \\ &F_k(x,y) = \sum_{i+j=k} a_{ij}x^i y^j, \qquad G_k(x,y) = \sum_{i+j=k} b_{ij}x^i y^j. \end{aligned}$$

It follows directly that

$$\begin{aligned} &P_3(\theta) = (a_{12}+b_{21})\sin^2\theta\cos^2\theta + a_{30}\cos^4\theta + b_{03}\sin^4\theta + K_0(\theta), \\ &P_2(\theta)S_2(\theta) = -a_{02}b_{02}\sin^6\theta + a_{20}b_{20}\cos^6\theta - N_1\sin^4\theta\cos^2\theta \\ &\quad - N_2\sin^2\theta\cos^4\theta + K_1(\theta), \end{aligned}$$

where K_0 and K_1 are 2π-periodic functions with zero mean value over the interval $[0, 2\pi]$, and

$$\begin{aligned} &N_1 = 2a_{02}a_{11} - 2b_{02}b_{11} + a_{02}b_{20} + a_{11}b_{11} + a_{20}b_{02} - a_{02}b_{02}, \\ &N_2 = 2a_{20}a_{11} - 2b_{20}b_{11} - a_{02}b_{20} - a_{11}b_{11} + a_{20}b_{20} - a_{20}b_{02}. \end{aligned}$$

Then we have

$$\frac{1}{2\pi}\int_0^{2\pi} R_3(\theta)\,\mathrm{d}\theta = -\frac{\pi}{2\pi b}\biggl[(a_{30}+b_{03})\frac{3}{4}+(a_{12}+b_{21})\frac{1}{4} \\ -\frac{1}{b}\biggl[(a_{02}b_{02}-a_{20}b_{20})\frac{5}{8}+(N_1+N_2)\frac{1}{8}\biggr]\biggr].$$

Thus, the conclusion follows from Lemma 2.2(ii). □

Along the above line one can find formulas for computing v_5, v_7, etc. See [31] for more detail.

2.2. *Normal form and Lyapunov technique*

Next, we introduce another method (called normal form method) to find focus values.

LEMMA 2.3. *Let* $a = d = 0$, $b = -c \neq 0$. *Then for any integer* $m \geqslant 1$ *there exists a polynomial change of variables of the form*

$$(x, y)^{\mathrm{T}} = (u, v)^{\mathrm{T}} + \mathrm{O}\bigl(|u, v|^2\bigr) = Q(u, v)$$

which transforms the system (2.1) *into*

$$\begin{aligned} \dot{u} &= bv + \sum_{j=1}^{m}(a_j u + b_j v)\bigl(u^2+v^2\bigr)^j + \mathrm{O}\bigl(|u, v|^{2m+2}\bigr), \\ \dot{v} &= -bu + \sum_{j=1}^{m}(-b_j u + a_j v)\bigl(u^2+v^2\bigr)^j + \mathrm{O}\bigl(|u, v|^{2m+2}\bigr). \end{aligned} \tag{2.11}$$

PROOF. For convenience we introduce complex variables $z = x + \mathrm{i}y$, $\bar{z} = x - \mathrm{i}y$, or

$$\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \begin{pmatrix} 1 & \mathrm{i} \\ 1 & -\mathrm{i} \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} \tag{2.12}$$

so that (2.1) becomes

$$\begin{aligned} \dot{z} &= f\left(\frac{z+\bar{z}}{2}, \frac{z-\bar{z}}{2\mathrm{i}}\right) + \mathrm{i}g\left(\frac{z+\bar{z}}{2}, \frac{z-\bar{z}}{2\mathrm{i}}\right) \equiv h(z, \bar{z}), \\ \dot{\bar{z}} &= f\left(\frac{z+\bar{z}}{2}, \frac{z-\bar{z}}{2\mathrm{i}}\right) - \mathrm{i}g\left(\frac{z+\bar{z}}{2}, \frac{z-\bar{z}}{2\mathrm{i}}\right) \equiv \bar{h}(z, \bar{z}). \end{aligned} \tag{2.13}$$

It is easy to verify that $\bar{h}$ is the conjugate of h. Hence, we may neglect the second equation in (2.13), since it can be obtained from the first one by taking complex conjugation.

By (2.3) we can write

$$h(z,\bar{z}) = -\mathrm{i}bz + \sum_{2\leqslant j+k\leqslant 2m+1} A_{jk} z^j \bar{z}^k + \mathrm{O}\big(|z|^{2m+2}\big). \tag{2.14}$$

We would like to make a change of variables of the form

$$z = \omega + \sum_{2\leqslant j+k\leqslant 2m+1} C_{jk}\omega^j \overline{\omega}^k = \omega + p(\omega,\overline{\omega}), \tag{2.15}$$

and expect that the resulting equation which has the form in general

$$\dot{\omega} = -\mathrm{i}b\omega + \sum_{2\leqslant j+k\leqslant 2m+1} B_{jk}\omega^j \overline{\omega}^k + \mathrm{O}\big(|\omega|^{2m+2}\big) \tag{2.16}$$

is as simple as possible.

For the purpose, differentiating both sides of (2.15) in t and using (2.13), (2.14) and (2.16) we obtain

$$\begin{aligned}
&\left[1 + \sum_{j+k=2}^{2m+1} C_{jk} j\omega^{j-1}\overline{\omega}^k\right]\left[-\mathrm{i}b\omega + \sum_{j+k=2}^{2m+1} B_{jk}\omega^j\overline{\omega}^k\right] \\
&\quad + \sum_{j+k=2}^{2m+1} C_{jk} k\omega^j\overline{\omega}^{k-1}\left[\mathrm{i}b\overline{\omega} + \sum_{j+k=2}^{2m+1} \overline{B}_{jk}\omega^k\overline{\omega}^j\right] \\
&= -\mathrm{i}b\left[\omega + \sum_{2\leqslant j+k\leqslant 2m+1} C_{jk}\omega^j\overline{\omega}^k\right] \\
&\quad + \sum_{j+k=2}^{2m+1} A_{jk}\big(\omega + p(\omega,\overline{\omega})\big)^j \big(\overline{\omega} + \bar{p}(\omega,\overline{\omega})\big)^k + \mathrm{O}\big(|\omega|^{2m+1}\big).
\end{aligned}$$

By considering terms of $\omega^j\overline{\omega}^k$ for $j+k=2$ we obtain

$$-\mathrm{i}bC_{jk} j\omega^j\overline{\omega}^k + B_{jk}\omega^j\overline{\omega}^k + \mathrm{i}bC_{jk} k\omega^j\overline{\omega}^k = -\mathrm{i}bC_{jk}\omega^j\overline{\omega}^k + A_{jk}\omega^j\overline{\omega}^k,$$

which yields

$$B_{jk} = A_{jk} + \mathrm{i}bC_{jk}(j-k-1). \tag{2.17}$$

Hence, to nullify the coefficients B_{jk} we can choose

$$C_{jk} = \frac{A_{jk}}{\mathrm{i}b(1+k-j)}$$

if

$$j \neq k+1, \tag{2.18}$$

which always holds for $j+k=2$. Thus it appears that $B_{jk}=0$ for the chosen C_{jk} for $j+k=2$. In other words, all quadratic terms will be nullified in the new equation (2.16) so far if we choose the coefficient of quadratic terms in (2.15) proper.

By equating the coefficients of $\omega^j\overline{\omega}^k$ for $j+k=3$, we obtain

$$B_{jk} = A_{jk} + \mathrm{i}bC_{jk}(j-k-1) + Z_{jk}, \tag{2.19}$$

where Z_{jk} depends on $C_{j'k'}$ with $j'+k'=2$. Thus, in this case, for j and k satisfying (2.18) we can also choose C_{jk} by

$$C_{jk} = \frac{1}{\mathrm{i}b(1+k-j)}[A_{jk}+Z_{jk}]$$

so that $B_{jk}=0$ for the new equation. The only monomial left up to now is $B_{21}\omega^2\overline{\omega}$ which is called a resonant term, and by (2.19) the coefficient C_{21} can be chosen freely, say $C_{21}=0$.

For higher values of $j+k$, the expression (2.19) remains valid, where Z_{jk} depends only on $C_{j'k'}$ with $2 \leqslant j'+k' < j+k$. Hence, by continuing the way above, an appropriate change of variables can be found that eliminates all those monomials $B_{jk}\omega^j\overline{\omega}^k$ for which (2.18) are satisfied. The only monomials which survive, called resonant terms, have the form $B_{k+1,k}\omega^{k+1}\overline{\omega}^k$. Therefore, eventually, Eq. (2.16) takes the form

$$\dot{\omega} = -\mathrm{i}b\omega + \sum_{k=1}^{m} B_{k+1,k}\omega^{k+1}\overline{\omega}^k + \mathrm{O}\big(|\omega|^{2m+2}\big) = R(\omega,\overline{\omega}).$$

More precisely, there exists a change of variables

$$z = \omega + p(\omega,\overline{\omega}), \qquad \overline{z} = \overline{\omega} + \bar{p}(\omega,\overline{\omega})$$

which carries (2.13) into the form of

$$\dot{\omega} = R(\omega,\overline{\omega}), \qquad \dot{\overline{\omega}} = \overline{R}(\omega,\overline{\omega}).$$

Substituting $\omega = u+\mathrm{i}v$, $\overline{\omega} = u-\mathrm{i}v$ into the above gives the desired system (2.11) with

$$a_j = \operatorname{Re} B_{j+1,j}, \quad b_j = -\operatorname{Im} B_{j+1,j}.$$

The coordinate change from (2.1) to (2.11) is given by

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 1 & \mathrm{i} \\ 1 & -\mathrm{i} \end{pmatrix}^{-1} \begin{pmatrix} \omega + p(\omega,\overline{\omega}) \\ \overline{\omega} + \bar{p}(\omega,\overline{\omega}) \end{pmatrix}, \qquad \begin{pmatrix} \omega \\ \overline{\omega} \end{pmatrix} = \begin{pmatrix} 1 & \mathrm{i} \\ 1 & -\mathrm{i} \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix}$$

where (x, y) and (u, v) are both real variables, and

$$\begin{pmatrix} 1 & \mathrm{i} \\ 1 & -\mathrm{i} \end{pmatrix}^{-1} = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ -\frac{\mathrm{i}}{2} & \frac{\mathrm{i}}{2} \end{pmatrix}.$$

The proof is completed. □

We call the system (2.11) the normal form of (2.1) of order $2m+1$. It is easy to see that in polar coordinates the normal form equation takes the form

$$\begin{aligned} \dot{r} &= a_1 r^3 + \cdots + a_m r^{2m+1} + \mathrm{O}\big(r^{2m+2}\big), \\ \dot{\theta} &= -\big(b + b_1 r^2 + \cdots + b_m r^{2m}\big) + \mathrm{O}\big(r^{2m+2}\big). \end{aligned} \tag{2.20}$$

For a relationship between focus values appeared in (2.5) and the constants a_j in (2.20) we have

LEMMA 2.4. *Let* $a = d = 0$, $b = -c \neq 0$. *Then* (2.5) *holds with* $k = 2m+1 \geqslant 3$ *if and only if* $a_j = 0$, $j = 1, \ldots, m-1$, $a_m \neq 0$. *Moreover,* $v_{2m+1} = a_m/|b|$ *as* $a_j = 0$, $j = 1, \ldots, m-1$.

PROOF. Let P and P^* denote respectively the Poincaré maps of (2.1) and (2.11) both associated to $\theta_0 = 0$. For $r_0 > 0$ small, let

$$\begin{aligned} &l\colon\ (x, y) = (r, 0), \quad 0 < r < r_0, \\ &l_1 = Q^{-1}(l) = \big\{\big(q_1(r), q_2(r)\big), 0 < r < r_0\big\}, \end{aligned}$$

where Q^{-1} is the inverse of the transformation Q appeared in Lemma 2.3, and $q_1(r) = r + \mathrm{O}(r^2)$, $q_2(r) = \mathrm{O}(r^2)$. Let $P_1 : l_1 \to l_1$ denote the Poincaré map of (2.11) defined by a similar way to (1.14). Then by the proof of Lemma 1.5 with the case 1 we have

$$P_1 = P. \tag{2.21}$$

Let $l' = \{(u, v)\colon\ u = r, v = 0, 0 < r < r_0\}$ which is tangent to l_1 at the origin. Denote by $(u(t, r),\ v(t, r))$ the solution of (2.11) with $(u(0, r),\ v(0, r)) = (r, 0)$. It is easy to see from (2.11) that

$$u(t, r) = r \cos bt + \mathrm{O}\big(r^2\big), \qquad v(t, r) = -r \sin bt + \mathrm{O}\big(r^2\big).$$

Note that l_1 can be represented as

$$l_1 = \big\{\big(r', c\big(r'\big)\big),\ 0 < r' < q_1(r_0)\big\}$$

where c is a C^∞ function satisfying $c(0) = c'(0) = 0$. Consider the function

$$K(t, r) = c\big(u(t, r)\big) - v(t, r) = r K_1(t, r),$$

where $K_1(t,r)=\sin bt+\mathrm{O}(r)$. By the implicit function theorem, there exists a C^∞ function $\tau^*(r)=\mathrm{O}(r)$ such that $K_1(\tau^*(r),r)\equiv 0$. Then similar to (1.10), there exists a unique function $h_1(r)$ such that

$$\big(u\big(\tau^*(r),r\big),v\big(\tau^*(r),r\big)\big)=\big(q_1\big(h_1(r)\big),q_2\big(h_1(r)\big)\big)\in l_1. \tag{2.22}$$

Moreover, the function satisfies

$$h_1\circ P^*=P_1\circ h_1. \tag{2.23}$$

By (2.22) it follows that

$$q_1(h_1)=u(\tau^*,r)=r\cos b\tau^*+\mathrm{O}\big(r^2\big)=r+\mathrm{O}\big(r^2\big),$$

which gives that

$$h_1=q_1^{-1}\big(r+\mathrm{O}\big(r^2\big)\big)=r+\mathrm{O}\big(r^2\big).$$

Therefore, by (2.21) and (2.23) we obtain

$$h_1\circ P^*=P\circ h_1,\quad h_1(r)=r+\mathrm{O}\big(r^2\big). \tag{2.24}$$

Then, it is easy to verify that (2.5) holds if and only if

$$P^*-r=2\pi v_k r^k+\mathrm{O}\big(r^{k+1}\big),\quad v_k\neq 0. \tag{2.25}$$

On the other hand, let $a_j=0,\ j=1,\dots,n-1, a_n\neq 0$. We then have from (2.20)

$$\frac{\mathrm{d}r}{\mathrm{d}\theta}=-\frac{a_n}{b}r^{2n+1}+\mathrm{O}\big(r^{2n+2}\big)$$

which has the solution

$$r(\theta,r_0)=r_0-\frac{a_n}{b}\theta r_0^{2n+1}+\mathrm{O}\big(r_0^{2n+2}\big).$$

Thus,

$$r(2\pi,r_0)=r_0-\frac{2\pi a_n}{b}r_0^{2n+1}+\mathrm{O}\big(r_0^{2n+2}\big).$$

Hence, by Lemma 2.2 we have

$$P^*(r)=r+\frac{2\pi a_n}{|b|}r^{2n+1}+\mathrm{O}\big(r^{2n+2}\big).$$

Obviously, for $n\geqslant 1$ the above holds if and only if (2.25) holds with $k=2m+1=2n+1$. This ends the proof. □

We remark that some algorithms have been established for calculating the coefficients $a_1, \dots, a_m$ in (2.20). An efficient one can be found in Yu [119].

We finally give a third method to determine the stability and the order of a focus originated by Lyapunov.

LEMMA 2.5. *For any given integer* $N > 1$ *and expansions of* f *and* g *of the form*

$$f = by + f_1 + \mathrm{O}\big(|x, y|^{2N+2}\big), \qquad g = -bx + g_1 + \mathrm{O}\big(|x, y|^{2N+2}\big),$$

where

$$f_1(x, y) = \sum_{2 \leqslant i+j \leqslant 2N+1} a_{ij} x^i y^j, \quad g_1(x, y) = \sum_{2 \leqslant i+j \leqslant 2N+1} b_{ij} x^i y^j,$$

there exist constants $L_2, \dots, L_{N+1}$ *and a polynomial*

$$V(x, y) = \sum_{k=2}^{2N+2} V_k(x, y),$$

where

$$V_2(x, y) = x^2 + y^2, \qquad V_k(x, y) = \sum_{i+j=k} c_{ij} x^i y^j, \quad 3 \leqslant k \leqslant 2N+2$$

such that

$$V_x f + V_y g = \sum_{k=2}^{N+1} L_k \big(x^2 + y^2\big)^k + \mathrm{O}\big(|x, y|^{2N+3}\big). \tag{2.26}$$

Moreover, for $2 \leqslant k \leqslant N+1$, L_{k+1} *depends only on* a_{ij} *and* b_{ij} *with* $i + j \leqslant 2k + 1$.

PROOF. We want to find a polynomial V with the supposed form and constants $L_2, \dots, L_{N+1}$ satisfying (2.26). Note that for the given form of f, g and V we have

$$\begin{aligned} V_x f + V_y g &= b(yV_x - xV_y) + (V_x f_1 + V_y g_1) + \mathrm{O}\big(|x, y|^{2N+3}\big) \\ &= b \sum_{k=3}^{2N+2} (yV_{kx} - xV_{ky}) - \sum_{k=3}^{2N+2} G_k + \mathrm{O}\big(|x, y|^{2N+3}\big), \end{aligned}$$

where

$$\sum_{k=3}^{2N+2} G_k = -(V_x f_1 + V_y g_1) + \mathrm{O}\big(|x, y|^{2N+3}\big) \tag{2.27}$$

with G_k being a homogeneous polynomial of degree k depending only on the coefficients a_{ij}, b_{ij} and c_{ij} with $2 \leqslant i + j < k$.

Then neglecting terms of degree more than $2N+2$ Eq. (2.26) is equivalent to

$$b \sum_{k=3}^{2N+2} (yV_{kx} - xV_{ky}) = \sum_{k=3}^{2N+2} G_k + \sum_{k=2}^{N+1} L_k \bigl(x^2 + y^2\bigr)^k.$$

In order to find V_k and L_k satisfying this equation it suffices to solve the following equation for $3 \leqslant k \leqslant 2N+2$:

$$b(yV_{kx} - xV_{ky}) = G_k \qquad \text{for } k \text{ odd,} \tag{2.28}$$

$$b(yV_{kx} - xV_{ky}) = G_k + L_{k/2}\bigl(x^2 + y^2\bigr)^{k/2} \quad \text{for } k \text{ even.} \tag{2.29}$$

The above equations can be rewritten as

$$b\frac{\mathrm{d}}{\mathrm{d}\theta} V_k(\cos\theta, \sin\theta) = G_k(\cos\theta, \sin\theta) \qquad \text{for } k \text{ odd,} \tag{2.30}$$

$$b\frac{\mathrm{d}}{\mathrm{d}\theta} V_k(\cos\theta, \sin\theta) = L_{k/2} + G_k(\cos\theta, \sin\theta) \quad \text{for } k \text{ even} \tag{2.31}$$

since

$$b(yV_{kx} - xV_{ky})(r\cos\theta, r\sin\theta) = b\,r^k \frac{\mathrm{d}}{\mathrm{d}\theta} V_k(\cos\theta, \sin\theta).$$

Let us solve (2.30) and (2.31) by induction in k. First, for $k = 3$, we have

$$\int_0^{2\pi} G_3(\cos\theta, \sin\theta)\,\mathrm{d}\theta = 0.$$

Hence there is a function $\widetilde{G}_3$ of the form

$$\widetilde{G}_3(\theta) = \sum_{i+j=3} \tilde{g}_{ij} \cos^i\theta \sin^j\theta$$

such that $\widetilde{G}_3'(\theta) = G_3(\cos\theta, \sin\theta)$. Denote $\widetilde{G}_3$ by

$$\widetilde{G}_3(\theta) = \int G_3(\cos\theta, \sin\theta)\,\mathrm{d}\theta.$$

We can write

$$\int G_3(\cos\theta, \sin\theta)\,\mathrm{d}\theta = \sum_{i+j=3} \tilde{g}_{ij} \cos^i\theta \sin^j\theta.$$

Then by (2.30) we have a solution for V_3 below

$$V_3(x,y)=\frac{1}{b}\sum_{i+j=3}\tilde{g}_{ij}x^i y^j.$$

That is, we have $c_{ij}=\frac{1}{b}\tilde{g}_{ij}$ for $i+j=3$.

For $k=4$, G_4 will be known when V_3 is definite. Thus, we can choose L_2 to be such that

$$L_2+\frac{1}{2\pi}\int_0^{2\pi}G_4(\cos\theta,\sin\theta)\,\mathrm{d}\theta=0.$$

It then follows that

$$\int\bigl[L_2+G_4(\cos\theta,\sin\theta)\bigr]\,\mathrm{d}\theta=\sum_{i+j=4}\tilde{g}_{ij}\cos^i\theta\sin^j\theta$$

as before. By (2.31), V_4 will be determined by taking $c_{ij}=\frac{1}{b}\tilde{g}_{ij}$ for $i+j=4$.

For higher values of k, V_k can be determined in the same procedure. This ends the proof. □

The following lemma says that the first nonzero constants of $L_2,\dots,L_{N+1}$ will determine the stability and the order of the focus of (2.11) at the origin if $a=0$.

LEMMA 2.6. *Let $a=d=0$, $b=-c\neq 0$. Then* (2.5) *holds with $k=2m+1\geqslant 3$ if and only if*

$$L_j=0,\quad j=2,\dots,m,\qquad L_{m+1}\neq 0.$$

Moreover, $v_{2m+1}=\frac{L_{m+1}}{2|b|}$ as $L_j=0$, $j=2,\dots,m$.

PROOF. Let $r>0$ be small and L denote the orbit arc of (2.1) from $(r,0)$ to $(P(r),0)$. Note that for any $\mu\in(0,1)$,

$$r+\mu\bigl[P(r)-r\bigr]=r+\mathrm{O}\bigl(r^3\bigr).$$

The mean value theorem implies that

$$\begin{aligned}V\bigl(P(r),0\bigr)-V(r,0)&=V_x\bigl(r+\mu\bigl[P(r)-r\bigr],0\bigr)\bigl(P(r)-r\bigr)\\&=2r\bigl[P(r)-r\bigr]\bigl(1+\mathrm{O}\bigl(r^2\bigr)\bigr),\end{aligned}$$

where V is the function in Lemma 2.5.

On the other hand, by the formula of constant variation we have $x^2+y^2=r^2(1+\mathrm{O}(r))$ along L. Thus, by (2.26)

$$V\big(P(r),0\big) - V(r,0) = \int_L \mathrm{d}V = \int_L (V_x f + V_y g)\,\mathrm{d}t$$
$$= \int_0^{\tau(r)} \left[\sum_{k=2}^{N+1} L_k r^{2k}\big(1+\mathrm{O}(r)\big) + \mathrm{O}\big(r^{2N+3}\big)\right]\mathrm{d}t$$
$$= \frac{2\pi}{|b|}\sum_{k=2}^{N+1} L_k r^{2k}\big(1+\mathrm{O}(r)\big) + \mathrm{O}\big(r^{2N+3}\big),$$

where $\tau(r) = \frac{2\pi}{|b|} + \mathrm{O}(r)$ is the time along L. It follows that

$$P(r) - r = \frac{\pi}{|b|}\sum_{k=2}^{N+1} L_k r^{2k-1}\big(1+\mathrm{O}(r)\big) + \mathrm{O}\big(r^{2N+2}\big).$$

Then the conclusion follows easily and the proof is completed. □

The proof of Lemma 2.6 presents an algorithm to compute constants $L_2, L_3, \ldots$. It includes the following three steps in a loop:

(i) Find G_{2m+1} by (2.27),
(ii) Find V_{2m+1} by (2.30),
(iii) Find G_{2m+2}, L_{m+1} and V_{2m+2} by (2.31).

To begin with $m = 1$ we can get L_2 by executing the 3 steps. We can get L_3 further by doing the same procedure for $m = 2$. See Chicone [14] for more detail.

By (2.3) and (2.5) we can prove the following corollary in a similar way to Lemma 2.6.

COROLLARY 2.1. *Let* $a = d = 0$, $b = -c \neq 0$. *Suppose there exists a function* $\widetilde{V}(x, y) = x^2 + y^2 + \mathrm{O}(|x, y|^3)$ *such that*

$$\dot{\widetilde{V}} = \widetilde{V}_x f + \widetilde{V}_y g = H_{2k}(x, y) + \mathrm{O}\big(|x, y|^{2k+1}\big), \quad k \geqslant 2,$$

where H_{2k} *is a homogeneous polynomial of order* $2k$ *satisfying*

$$\widetilde{L}_k = \frac{|b|}{2\pi}\int_0^{2\pi/|b|} H_{2k}(\cos bt, -\sin bt)\,\mathrm{d}t < 0 \ (> 0).$$

Then the origin is a stable (*unstable*) *focus of order* $k-1$ *of Eq.* (2.1).

Now let us recall some facts obtained so far in this section. We will outline them for analytic systems. Suppose f and g in (2.1) are analytic functions near the origin and (2.3) holds with $a + d = 0$. Then by Lemma 2.1, the proof of Lemma 2.6 and the definition of the Poincaré map in (2.4) we have

$$P(r) - r = \frac{\pi}{|b|}\sum_{k=2}^{N+1} L_k r^{2k-1}\big(1+\mathrm{O}(r)\big) + \mathrm{O}\big(r^{2N+2}\big) = 2\pi\sum_{k=3}^{\infty} v_k r^k, \qquad (2.32)$$

where

$$v_{2m} = \mathrm{O}\big(|v_3, v_5, \ldots, v_{2m-1}|\big), \quad m \geqslant 2.$$

The implicit function theorem ensures the convergence of the series in the right-hand side of (2.32).

If $a = d = 0,\ b = -c \neq 0$, by Lemma 2.3, there exists a formal change of variables given by the formal series

$$(x, y)^{\mathrm{T}} = (u, v)^{\mathrm{T}} + \sum_{i+j\geqslant 2} q_{ij} u^i v^j = Q(u, v)$$

which carries (2.1) formally into

$$\begin{aligned} \dot{u} &= bv + \sum_{j\geqslant 1} (a_j u + b_j v)\big(u^2 + v^2\big)^j, \\ \dot{v} &= -bu + \sum_{j\geqslant 1} (-b_j u + a_j v)\big(u^2 + v^2\big)^j. \end{aligned} \tag{2.33}$$

By Lemma 2.5, there exist a formal series

$$V(x, y) = x^2 + y^2 + \sum_{i+j\geqslant 3} c_{ij} x^i y^j$$

and constants $L_2, L_3, \ldots$, such that

$$V_x f + V_y g = \sum_{k\geqslant 2} L_k \big(x^2 + y^2\big)^k. \tag{2.34}$$

Lemmas 2.4 and 2.6 show that the following three statements are equivalent to each other:

(i) $v_{2j+1} = 0,\ j = 1, \ldots, m-1,\ v_{2m+1} \neq 0$;

(ii) $a_j = 0,\ j = 1, \ldots, m-1,\ a_m \neq 0$;

(iii) $L_j = 0,\ j = 1, \ldots, m,\ L_{m+1} \neq 0$.

Moreover, when one of the conditions (i)–(iii) holds, we have

$$v_{2m+1} = \frac{a_m}{|b|} = \frac{L_{m+1}}{2|b|}.$$

Based on this relationship, we call either v_{2m+1}, a_m or L_{m+1} the mth Lyapunov quantity or focus value.

Note that the series in (2.32) is always convergent for $|r|$ small if (2.1) is analytic. We therefore obtain

THEOREM 2.2. *Suppose* (2.1) *is an analytic system satisfying* $a = d = 0,\ b = -c \neq 0$. *Then* (2.1) *has a center at the origin if and only if one of the following holds*:

(a) $v_{2k+1} = 0$ *for all* $k \geqslant 1$;
(b) $a_k = 0$ *for all* $k \geqslant 1$;
(c) $L_k = 0$ *for all* $k \geqslant 2$.

Lyapunov proved that the formal series for $V(x, y)$ is convergent near the origin if $L_k = 0$ for all $k \geqslant 2$. Hence, by (2.34) in this case the function V represents a first integral whose level sets are orbits of the system (2.1).

Bryuno [9] proved that the formal series for $Q(u, v)$ is convergent near the origin if and only if $a_k = 0$ for all $k \geqslant 1$. In this case, system (2.33) becomes

$$\dot{u} = v\left[b + \sum_{j\geqslant 1} b_j\bigl(u^2 + v^2\bigr)^j\right],$$
$$\dot{v} = -u\left[b + \sum_{j\geqslant 1} b_j\bigl(u^2 + v^2\bigr)^j\right]$$

which has a first integral of the form $u^2 + v^2$. This implies that the original system (2.1) has a first integral of the form $W_1^2(x, y) + W_2^2(x, y)$, where $W(x, y) = (W_1(x, y), W_2(x, y))$ is the inverse of the coordinate change $(x, y)^{\mathrm{T}} = Q(u, v)$.

Thus, by Theorem 2.2 and the next theorem we know that under the condition of Theorem 2.2 system (2.1) has a center at the origin if and only if it has an analytic first integral of the form $x^2 + y^2 + \mathrm{O}(|x, y|^3)$.

The following theorem gives a sufficient condition for (2.1) to have a center at the origin.

THEOREM 2.3. *Consider the* C^∞ *system* (2.1). *Let* (2.2) *hold. If one of the conditions below is satisfied*:
(i) $f(-x, y) = f(x, y)$, $g(-x, y) = -g(x, y)$;
(ii) *there exists a* C^∞ *function* $H(x, y)$ *for* (x, y) *near the origin satisfying* $H(0, 0) = 0$, $H(x, y) \neq 0$ *for* $0 < x^2 + y^2 \ll 1$ *such that* $H_x f + H_y g = 0$,
then (2.1) *has a center at the origin.*

PROOF. Let (i) hold first. Without loss of generality we assume that the orbits of (2.1) near the origin are oriented clockwise. For $y_0 > 0$ small let $(x(t), y(t))$ be the solution of (2.1) with $(x(0), y(0)) = (0, y_0)$. Set

$$L_1 = \bigl\{\bigl(x(t), y(t)\bigr) \mid 0 \leqslant t \leqslant t_1\bigr\}, \qquad L_2 = \bigl\{\bigl(x(t), y(t)\bigr) \mid t_1 \leqslant t \leqslant t_2\bigr\},$$
$$L_1' = \bigl\{\bigl(-x(-t), y(-t)\bigr) \mid -t_1 \leqslant t \leqslant 0\bigr\},$$

where

$$t_1 = \min\bigl\{t > 0 \mid x(t) = 0, y(t) < 0\bigr\}, \qquad t_2 = \min\bigl\{t > 0 \mid x(t) = 0, y(t) > 0\bigr\}.$$

By our assumption, L_1' is an orbit arc of (2.1) starting at $(0, y(t_1))$. This implies that $L_2 = L_1'$ and hence $y(t_2) = y_0$. In other words, $(x(t), y(t))$ is a periodic solution.

Now let (ii) hold. For definiteness, we suppose $H(x, y) > 0$ for $0 < x^2 + y^2 \ll 1$. Then the function $z = H(x, y)$ takes a minimal value at $(x, y) = (0, 0)$. This implies that for sufficiently small $h > 0$, the equation $H(x, y) = h$ defines a closed curve near the origin. Our assumption ensures that the curve is a periodic orbit which approaches the origin as $h \to 0$. The proof is completed. □

EXAMPLE 2.1. Consider a C^∞ system of the form

$$\dot{x} = y - xh(x, y), \qquad \dot{y} = -x - yh(x, y),$$

where

$$h(x, y) = \begin{cases} 0, & \text{for } (x, y) = (0, 0), \\ \mathrm{e}^{-\frac{1}{x^2+y^2}}, & \text{otherwise.} \end{cases}$$

Let $V(x, y) = x^2 + y^2$. Then for the system, (2.34) becomes

$$V_x f + V_y g = -2\left(x^2 + y^2\right)h(x, y) < 0$$

for $x^2 + y^2 > 0$. By the proof of Lemma 2.6, the origin is a stable focus. However, in this case we have $L_k = 0$ for all $k \geqslant 2$.

This example shows that Theorem 2.2 is no longer true for C^∞ systems.

EXAMPLE 2.2. Consider the following cubic Liénard system:

$$\begin{aligned} &\dot{x} = y - \left(a_3x^3 + a_2x^2 + a_1x\right), \\ &\dot{y} = -x, \end{aligned} \tag{2.35}$$

where a_1, a_2 and a_3 are real constants. The divergence of (2.35) takes value $-a_1$ at the origin. Hence, the origin is a stable (unstable) focus if $a_1 > 0$ (< 0). Further, by Theorem 2.1 we have $V_3 = -\frac{3}{8}a_3$ as $a_1 = 0$. Thus, in this case, the origin is stable (unstable) if $a_3 > 0$ (< 0).

Let $a_1 = a_3 = 0$. Theorem 2.3(i) implies that (2.35) has a center at the origin now.

EXAMPLE 2.3. For a given C^∞ function $H : \mathbb{R}^2 \to \mathbb{R}$, it induces a planar system of the form

$$\dot{x} = H_y, \qquad \dot{y} = -H_x$$

which is called a Hamiltonian system with the Hamiltonian function H. The level sets of the function give orbits of the system. By Theorem 2.3(ii), if there is a point $(x_0, y_0) \in \mathbb{R}^2$

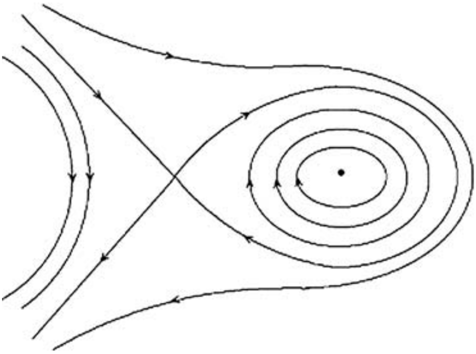

Fig. 6. The phase portrait of (2.36) with $g(x) = x^2 - x$.

satisfying

$$H_x(x_0, y_0) = H_y(x_0, y_0) = 0,$$
$$-\big[H_{xy}(x_0, y_0)\big]^2 + H_{xx}(x_0, y_0)H_{yy}(x_0, y_0) > 0$$

then the above Hamiltonian system has a center at the point.

For example, let

$$H(x, y) = \frac{1}{2}y^2 + G(x).$$

Then the induced system is

$$\dot{x} = y, \qquad \dot{y} = -g(x), \tag{2.36}$$

where $g(x) = G'(x)$. In mechanics, the function H is called the total energy of the system (2.36), while the term $\frac{1}{2}y^2$ is called the kinetic energy and the function G is the potential energy. It is evident that (2.36) has a center at point $(x_0, 0)$ if $g(x_0) = 0,\ g'(x_0) > 0$. A singular point $(x_0, 0)$ satisfying $g'(x_0) < 0$ is a saddle point. Taking $g(x) = x^2 - x$, (2.34) becomes

$$\dot{x} = y, \qquad \dot{y} = x - x^2$$

which has two singular points: center (1,0) and saddle (0,0). Note that $H(0, 0) = 0$. There is a nontrivial orbit γ defined by the equation $H(x, y) = 0$. The orbit approaches the saddle point both positively and negatively. An orbit with this property is called a homoclinic orbit. The phase portrait of the above quadratic Hamiltonian system has been drawn in Fig. 6.

2.3. *Hopf bifurcation*

In the next part, we consider a planar C^∞ system with a vector parameter of the form

$$\dot{x} = f(x, y, \mu), \qquad \dot{y} = g(x, y, \mu), \tag{2.37}$$

where $\mu \in \mathbb{R}^m$, $m \geqslant 1$. Suppose (2.37) has an elementary focus for $\mu = 0$. Without loss of generality we can assume that for all small $|\mu|$ (2.37) has a focus at the origin. Then we can write near the origin

$$\begin{aligned} f(x, y, \mu) &= a(\mu)x + b(\mu)y + \mathrm{O}\big(|x, y|^2\big), \\ g(x, y, \mu) &= c(\mu)x + d(\mu)y + \mathrm{O}\big(|x, y|^2\big), \end{aligned} \tag{2.38}$$

where $a(0) = d(0)$, $b(0) = -c(0) \neq 0$.

Let $P(r, \mu)$ denote the Poincaré map of (2.37) near the origin. By Lemma 2.1, similar to (2.32) for any integer $N > 0$, P has the following expansion:

$$P(r, \mu) = r + 2\pi \sum_{k=1}^{N} v_k(\mu) r^k + \mathrm{O}\big(r^{N+1}\big), \tag{2.39}$$

where

$$v_{2m} = \mathrm{O}\big(|v_1, v_3, \ldots, v_{2m-1}|\big), \quad 1 \leqslant m \leqslant \frac{N}{2}. \tag{2.40}$$

Sometimes, for convenience, we call $v_{2m+1}(\mu)$ in (2.39) the mth Lyapunov constant of (2.37) at the origin, $m \geqslant 1$. Introduce

$$d(r, \mu) = P(r, \mu) - r,$$

which is called a succession function or bifurcation function of (2.37). This function is also called the displacement function.

By using an analogous formula to (2.6) it is easy to obtain

LEMMA 2.7. *For* $|\mu|$ *small, Eq.* (2.37) *has a limit cycle near the origin if and only if there exist* $r_1(\mu) > 0$, $r_2(\mu) < 0$ *near* $r = 0$ *such that*

$$d\big(r_j(\mu), \mu\big) = 0, \quad j = 1, 2.$$

By (2.38) and the discussion after Remark 2.2 we know that $v_1(\mu)$ has the same sign as $a(\mu) + d(\mu)$. In fact, $v_1(\mu) = \frac{1}{2\pi}[\mathrm{e}^{2\pi\alpha/|\beta|} - 1]$ with $\alpha = \frac{1}{2}(a + d)$, $|\beta| = \frac{1}{2}\sqrt{-4bc - (a - d)^2}$. Hence, if $a(0) + d(0) \neq 0$ then $v_1(0) \neq 0$ and $d(r, \mu)$ has no positive zero near $r = 0$ for all $|\mu|$ small. Thus, if $a(0) + d(0) \neq 0$, there is no limit cycle near the origin for all $|\mu|$ small.

Let $a(0)+d(0)=0$, and let v_{30} denote the first order focus value of (2.37) for $\mu=0$ at the origin. Then by (2.39) and (2.40) we have

$$d(r,\mu)=2\pi r\bigl[v_1(\mu)+v_2(\mu)r+v_3(\mu)r^2+\mathrm{O}\bigl(r^3\bigr)\bigr],$$

where $v_1(0)=v_2(0)=0,\ v_3(0)=v_{30}$. Similar to Theorem 1.3(i) we can prove that if $v_{30}\neq 0,\ d(r,\mu)$ has two zeros in r with one positive and the other negative for $v_1(\mu)v_{30}<0$ and has no nontrivial zero for $v_1(\mu)v_{30}>0$. Thus, by Lemma 2.7 and noting

$$v_1=\frac{a(\mu)+d(\mu)}{2|b(0)|}\bigl(1+\mathrm{O}(\mu)\bigr),$$

we have proved the following

THEOREM 2.4. *If for $\mu=0$ (2.37) has a first order focus at the origin, then it has at most one limit cycle near the origin for all $|\mu|$ small. Moreover, the limit cycle exists if and only if $(a(\mu)+d(\mu))v_{30}<0$.*

In general, similar to Theorem 1.3(ii), we have:

THEOREM 2.5. *If for $\mu=0$ (2.37) has a kth order focus at the origin ($k\geqslant 2$), then it has at most k limit cycles near the origin for $|\mu|$ small. Moreover, k limit cycles can appear by suitable perturbations.*

EXAMPLE 2.4. Consider a cubic Liénard system

$$\begin{aligned}\dot{x}&=y-\bigl(x^5+\mu_1x^3+\mu_2x\bigr),\\ \dot{y}&=-x,\end{aligned}\tag{2.41}$$

where μ_1 and μ_2 are small parameters.

First, by (2.39) and (2.40), we have

$$\begin{aligned}v_1&=-\frac{1}{2}\mu_2+\mathrm{O}\bigl(\mu_2^2\bigr),\quad &v_2&=\mathrm{O}(\mu_2),\\ v_3&=-\frac{3}{8}\mu_1+\mathrm{O}(\mu_2),\quad &v_4&=\mathrm{O}\bigl(|v_1,v_3|\bigr).\end{aligned}$$

It is easy to check that for

$$V(x,y)=x^2+y^2-\frac{5}{8}xy^5-\frac{5}{3}x^3y^3-\frac{11}{8}x^5y$$

it holds along the orbits of (2.41)

$$\left.\frac{\mathrm{d}V}{\mathrm{d}t}\right|_{\mu_1=\mu_2=0}=-\frac{5}{8}\bigl(x^2+y^2\bigr)^3+\mathrm{O}\bigl(|x,y|^{10}\bigr).$$

Hence, by Lemma 2.6, it follows that

$$v_5 = -\frac{5}{16} + \mathrm{O}\big(|\mu_1, \mu_2|\big).$$

This shows that for $\mu_1 = \mu_2 = 0$ the origin is a stable focus of order 2 for (2.41).

We claim that there is a function

$$\delta(\mu_1) = \frac{9}{40}\mu_1^2 + \mathrm{O}\big(|\mu_1|^{5/2}\big)$$

such that for $|\mu_1| + |\mu_2|$ small Eq. (2.41) has

(i) no limit cycle if either $\mu_1 \geqslant 0$ and $\mu_2 \geqslant 0$ or $\mu_1 < 0$ and $\mu_2 > \delta(\mu_1)$;
(ii) a unique simple limit cycle if either $\mu_1 \geqslant 0$ and $\mu_2 < 0$ or $\mu_1 < 0$ and $\mu_2 \leqslant 0$;
(iii) a unique double limit cycle if $\mu_1 < 0$ and $\mu_2 = \delta(\mu_1)$;
(iv) two simple limit cycles if $\mu_1 < 0$ and $\mu_2 < \delta(\mu_1)$.

In fact, by $v_2 = \mathrm{O}(v_1)$, $v_3 = -\frac{3}{8}\mu_1 + \mathrm{O}(v_1)$ and $v_4 = \mathrm{O}(|v_1| + |\mu_1|)$ we can write

$$\begin{aligned} d(r,\mu) &= 2\pi r P_1(r,u)\left[v_1 - \frac{3}{8}\mu_1 r^2 P_2(r,\mu) + v_5^* r^4 P_3(r,\mu)\right] \\ &= 2\pi r P_1(r,u) d_1(r,\mu), \end{aligned}$$

where $P_i = 1 + \mathrm{O}(r) \in C^\infty$, $i = 1, 2, 3$, $v_5^* = -\frac{5}{16} + \mathrm{O}(|\mu_1|)$. The function d_1 can be written further as

$$d_1(r,\mu) = v_1 - \frac{3}{8}\mu_1\rho^2 + v_5^*\rho^4 P_3^*(\rho,\mu) \equiv d_2(\rho,\mu),$$

where $\rho = r\sqrt{P_2(r,\mu)} = r + \mathrm{O}(r^2) \in C^\omega$, $P_3^* = 1 + \mathrm{O}(\rho) \in C^\omega$.

Clearly, for $\mu_1 \geqslant 0$ we have $\frac{\partial d_2}{\partial\rho} < 0$ for $0 < \rho \ll 1$. This implies that for $\mu_1 \geqslant 0$, d_1 has a unique zero if and only if $v_1 > 0$. Note that Eq. (2.41) has a double limit cycle near the origin if and only if the function $d_2(\rho,\mu)$ has a double zero in ρ near $\rho = 0$. Let us consider the equations below

$$d_2(\rho,\mu) = 0, \qquad \frac{\partial d_2}{\partial\rho}(\rho,\mu) = 0.$$

We can solve form the above equations

$$\begin{aligned} \rho &= \sqrt{-\frac{3}{5}\mu_1}\big(1 + \delta_1\big(\sqrt{-\mu_1}\big)\big), \\ v_1 &= \frac{9}{256 v_5^*}\mu_1^2\big(1 + \delta_2\big(\sqrt{-\mu_1}\big)\big) \end{aligned}$$

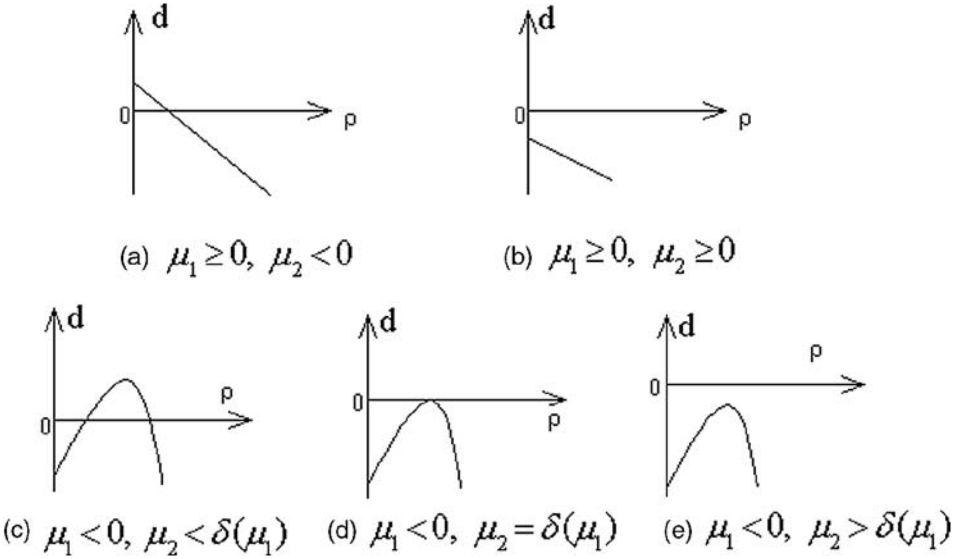

Fig. 7. Curves determined by $d_2(\rho, \mu)$.

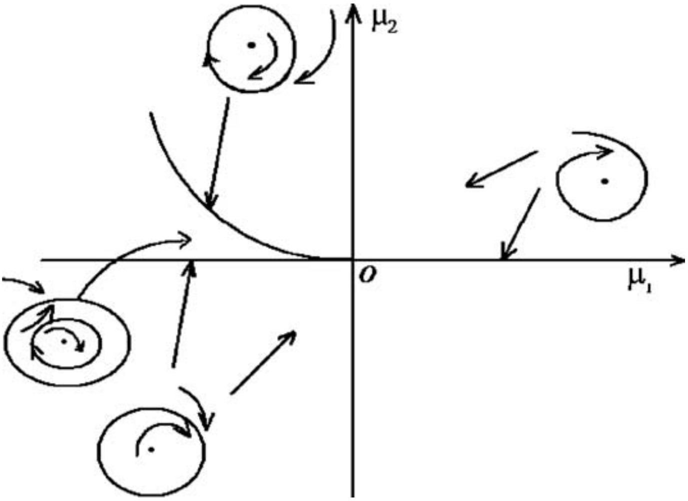

Fig. 8. The bifurcation diagram of (2.41).

for $\mu_1 < 0$, where $\delta_i(u) = \mathrm{O}(u) \in C^\omega,\ i = 1, 2$. The second equation above determines a unique function

$$\mu_2 = \delta(\mu_1) = \frac{9}{40}\mu_1^2 + \mathrm{O}\big(\mu_1^{5/2}\big).$$

Now it is easy to draw curves determined by the function $d = d_2(\rho, \mu)$ on (d, ρ) plane, see Fig. 7.

Then the claim follows easily. For the bifurcation diagram of (2.41) see Fig. 8.

On the (μ_1, μ_2) plane in Fig. 8, the line $\mu_2 = 0$ (near the origin) is Hopf bifurcation curve, and the curve $\mu_2 = \delta(\mu_1)$ is the double limit cycle bifurcation curve, or in other words, the saddle-node bifurcation curve for limit cycles.

If (2.37) has a center at the origin for $\mu = 0$, we can also study the bifurcation of limit cycles for $|\mu|$ small. We give an example to illustrate this phenomenon.

EXAMPLE 2.5. Consider the cubic system

$$\begin{aligned} \dot{x} &= y + x^2 + \varepsilon\big(x^3 - \varepsilon x\big), \\ \dot{y} &= -\big(x - x^3\big). \end{aligned}$$

We prove that the system has a unique limit cycle near the origin for $0 < \varepsilon \ll 1$.

For the purpose, let us consider

$$\begin{aligned} \dot{x} &= y + x^2 + \varepsilon\big(x^3 - \delta x\big), \\ \dot{y} &= -\big(x - x^3\big), \end{aligned} \tag{2.42}$$

and prove that the system has a unique limit cycle near the origin for $0 < |\varepsilon| < \varepsilon_0,\ 0 < \delta < \varepsilon_0$ for a small constant $\varepsilon_0 > 0$.

First, by Theorem 2.3(i), (2.42) has a center at the origin for $\varepsilon = 0$. Hence, the succession function $d(r, \varepsilon, \delta)$ of (2.42) can be written as

$$\begin{aligned} d(r, \varepsilon, \delta) &= 2\pi\varepsilon r\big[v_1^*(\varepsilon, \delta) + v_2^*(\varepsilon, \delta)r + v_3^*(\varepsilon, \delta)r^2 + \mathrm{O}\big(r^3\big)\big] \\ &= 2\pi\varepsilon r d^*(r, \varepsilon, \delta), \end{aligned}$$

where

$$\varepsilon v_1^* = v_1 = \frac{1}{2\pi}\big[\mathrm{e}^{-\varepsilon\delta\pi} - 1\big] = -\frac{\varepsilon\delta}{2}\big(1 + \mathrm{O}(\varepsilon\delta)\big),$$

$$v_2^* = \mathrm{O}\big(v_1^*\big), \quad \varepsilon v_3^* = v_3 = \frac{3}{8}\varepsilon + \mathrm{O}(v_1).$$

Therefore,

$$d^* = -\frac{\delta}{2}\big(1 + \mathrm{O}(\varepsilon\delta)\big) + \mathrm{O}(\delta)r + \left(\frac{3}{8} + O(\delta)\right)r^2 + \mathrm{O}\big(r^3\big)$$

which has a positive zero $r = \frac{2}{\sqrt{3}}\sqrt{\delta}(1 + \mathrm{O}(\varepsilon\delta))$ near $r = 0$ if $0 < \delta \ll 1$. Then the conclusion for (2.42) follows directly.

2.4. *Degenerate Hopf bifurcation*

We now turn to the degenerate Hopf bifurcation near a center and establish a general theory by using the first order Melnikov function.

Consider a C^∞ planar system of the form

$$\begin{aligned} \dot{x} &= f(x,y) + \varepsilon p(x,y,\varepsilon,\delta), \\ \dot{y} &= g(x,y) + \varepsilon q(x,y,\varepsilon,\delta), \end{aligned} \tag{2.43}$$

where $\varepsilon \in \mathbb{R}$, $\delta \in D \subset \mathbb{R}^m$ $(m \geqslant 1)$ with D compact, and

$$\left.\begin{aligned} &\big(f(x,y), g(x,y)\big) = \mu(H_y, -H_x), \quad \mu = \pm 1, \\ &H(x,y) = K\big(x^2+y^2\big) + \mathrm{O}\big(|x,y|^3\big), \quad K > 0, \\ &p(0,0,\varepsilon,\delta) = q(0,0,\varepsilon,\delta) = 0. \end{aligned}\right\} \tag{2.44}$$

Then for $0 < h \ll 1$, the equation $H(x,y) = h$ defines a periodic orbit L_h of (2.43) $(\varepsilon = 0)$ which intersects the positive x-axis at $A(h) = (a(h), 0)$. Let $B(h,\varepsilon,\delta)$ denote the first intersection point of the positive orbit of (2.43) starting at $A(h)$ with the positive x-axis. Then by (2.44) we have

$$H(B) - H(A) = \int_{AB} \mathrm{d}H = \varepsilon\big[M(h,\delta) + \mathrm{O}(\varepsilon)\big], \tag{2.45}$$

where

$$\begin{aligned} M(h,\delta) &= \frac{1}{\mu}\oint_{L_h} (fq - gp)|_{\varepsilon=0}\,\mathrm{d}t = \frac{1}{\mu}\oint_{L_h} (q\,\mathrm{d}x - p\,\mathrm{d}y)|_{\varepsilon=0} \\ &= \frac{1}{|\mu|}\iint_{H\leqslant h} (p_x + q_y)|_{\varepsilon=0}\,\mathrm{d}x\,\mathrm{d}y. \end{aligned} \tag{2.46}$$

We call M the first order Melnikov function. We will see that the function plays an important role in the study of the number of limit cycles.

Let $u(t,c)$ be the solution of (2.43) $(\varepsilon = 0)$ with initial value $(c, 0)$. Then we have by (2.44)

$$\begin{aligned} &H\big(u(t,c)\big) = H(c,0) = r^2(c), \quad t \in \mathbb{R}, \\ &r(c) = c\sqrt{K + S(c)}, \quad S(c) = \mathrm{O}(c) \in C^\infty. \end{aligned}$$

Denote by $c = c(r) = \frac{r}{\sqrt{K}} + \mathrm{O}(r^2)$ the inverse of $r = r(c)$. Then

$$H\big(v(t,r)\big) = r^2, \qquad v\big(T(r), r\big) = \big(c(r), 0\big),$$

where $v(t,r) = u(t, c(r))$, and $T(r)$ is the period of the function v in t. Clearly, the functions $v(t,r)$ and $T(r)$ are both C^∞ with $T(0) = \frac{\pi}{K|\mu|} > 0$. Introduce a C^∞ function as follows:

$$G(\theta, r) = v\left(\frac{T(r)}{2\pi}\theta, r\right).$$

Obviously, $G = \mathrm{O}(r)$ is 2π-periodic in θ, and

$$H\big(G(\theta, r)\big) = r^2, \quad \theta \in \mathbb{R}. \tag{2.47}$$

LEMMA 2.8. *The change of variables*

$$(x, y)^{\mathrm{T}} = G(\theta, r) \tag{2.48}$$

transforms the system (2.43) *into the* C^∞ *system*

$$\begin{aligned} \dot\theta &= \frac{2\pi}{T(r)}\left[1 - \frac{\varepsilon}{2\mu r} G_r \wedge \big(p(G,\varepsilon,\delta), q(G,\varepsilon,\delta)\big)\right], \\ \dot r &= \frac{\varepsilon}{2r} DH(G) \cdot \big(p(G,\varepsilon,\delta), q(G,\varepsilon,\delta)\big)^{\mathrm{T}}. \end{aligned} \tag{2.49}$$

PROOF. Differentiating (2.48) in t yields

$$G_\theta \dot\theta + G_r \dot r = \big(f(G) + \varepsilon p(G,\varepsilon,\delta), g(G) + \varepsilon q(G,\varepsilon,\delta)\big)^{\mathrm{T}}. \tag{2.50}$$

By (2.47) and the definition of G, we have

$$\mathrm{D}H(G)G_\theta = 0, \qquad \mathrm{D}H(G)G_r = 2r, \qquad G_\theta = \frac{T(r)}{2\pi}\big(f(G), g(G)\big).$$

Multiplying (2.50) by $\mathrm{D}H(G)$ from the left-hand side gives

$$2r\dot r = \varepsilon \mathrm{D}H(G) \cdot \big(p(G,\varepsilon,\delta), q(G,\varepsilon,\delta)\big),$$

which gives the second equation in (2.49).

Further, noting that

$$G_r \wedge G_\theta = \frac{T(r)}{2\pi} G_r \wedge \big(f(G), g(G)\big) = -\frac{\mu T(r)}{2\pi} \mathrm{D}H(G)G_r = -\frac{\mu T(r)}{\pi} r,$$

it follows from (2.50) that

$$(G_r \wedge G_\theta)\dot\theta = G_r \wedge \big(f(G), g(G)\big) + \varepsilon G_r \wedge (p, q),$$

or

$$-\frac{\mu T(r)}{\pi} r\dot\theta = -2\mu r + \varepsilon G_r \wedge (p, q)$$

which gives the first equation in (2.49). The proof is completed. □

By (2.49) we obtain

$$\frac{\mathrm{d}r}{\mathrm{d}\theta} = \varepsilon R(\theta, r, \varepsilon, \delta), \tag{2.51}$$

where R is C^∞ and 2π-periodic in θ with $R = \mathrm{O}(r)$ and

$$R(\theta, r, \theta, \delta) = \frac{T(r)}{4\pi r} \mathrm{D}H(G) \cdot \big(p(G, 0, \delta), q(G, 0, \delta)\big)^{\mathrm{T}}. \tag{2.52}$$

Let $r(\theta, \rho, \varepsilon, \delta)$ denote the solution of (2.51) with $r(0, \rho, \varepsilon, \delta) = \rho$, and $(x(t, c, \varepsilon, \delta), y(t, c, \varepsilon, \delta))$ the solution of (2.43) with $(x(0, c, \varepsilon, \delta), y(0, c, \varepsilon, \delta)) = (c, 0)$. Then the Poincaré map $P(c, \varepsilon, \delta)$ of (2.43) is given by

$$P(c, \varepsilon, \delta) = x(\tau, c, \varepsilon, \delta) = P(c)$$

where

$$\tau = \min\big\{t > 0 \mid cx(t, c, \varepsilon, \delta) > 0,\ y(t, c, \varepsilon, \delta) = 0\big\}.$$

By the definition of G we have $G(0, r) = (c(r), 0)$ which yields

$$G\big(0, P_1(\rho)\big) = \big(c\big(P_1(\rho)\big), 0\big),$$

where

$$P_1(\rho) = r(2\pi, \rho, \varepsilon, \delta) = P_1(\rho, \varepsilon, \delta)$$

which is called the Poincaré map of (2.51).

On the other hand, by (2.48) for $c = c(\rho)$ we have

$$\big(P(c, \varepsilon, \delta), 0\big) = G\big(2\pi, r(2\pi, \rho, \varepsilon, \delta)\big) = G\big(0, P_1(\rho)\big).$$

Hence

$$\big(P\big(c(\rho), \varepsilon, \delta\big), 0\big) = \big(c\big(P_1(\rho)\big), 0\big),$$

or

$$P \circ c = c \circ P_1. \tag{2.53}$$

THEOREM 2.6. *Let* (2.43) *satisfy* (2.44). *Then*:

(i) *The function M is C^∞ at $h = 0$. It is analytic at $h = 0$ if* (2.43) *is analytic.*

(ii) *If there exist a compact subset* D_0 *of* D *and an integer* $k \geqslant 0$ *such that for* $0 < h \ll 1$

$$M(h,\delta) = B_k(\delta)h^{k+1} + \mathrm{O}\big(h^{k+2}\big), \quad B_k(\delta) \neq 0,\ \delta \in D_0, \tag{2.54}$$

then there exist $\varepsilon_0 > 0$, *an open set* $U(D_0) \supset D_0$ *and a neighborhood* V *of the origin such that* (2.43) *has at most* k *limit cycles in* V *for* $0 < |\varepsilon| < \varepsilon_0$, $\delta \in U(D_0)$.

PROOF. It is easy to see that the Poincaré map P_1 of (2.51) can be written as

$$P_1(r,\varepsilon,\delta) = r + \varepsilon r F(r,\varepsilon,\delta), \tag{2.55}$$

where

$$rF(r,0,\delta) = \int_0^{2\pi} R(\theta,r,0,\delta)\,\mathrm{d}\theta \equiv R_0(r,\delta).$$

By (2.44) and (2.52) we have

$$\begin{aligned} R_0(r,\delta) &= \frac{1}{2r\mu}\oint_{H=r^2} (f,g)\wedge(p,q)|_{\varepsilon=0}\,\mathrm{d}t \\ &= \frac{1}{2r\mu}\oint_{H=r^2} (q\,\mathrm{d}x - p\,\mathrm{d}y)|_{\varepsilon=0} \end{aligned} \tag{2.56}$$

which immediately follows $R_0(-r,\delta) = -R_0(r,\delta)$. Hence, the function $M^*(r)$ defined by

$$M^*(r) = 2rR_0(r,\delta)$$

is even. Since $M^* \in C^\infty$, for any integer $j > 1$, we have

$$M^*(r) = \sum_{i=1}^{j} A_i r^{2i} + N(r),$$

where $N \in C^\infty$ is even and $N^{(i)}(0) = 0$, $i = 0,1,\dots,2j$.

Let $\overline{N}(h) = N(\sqrt{h})$. We claim that

$$\overline{N}^{(i)}(0) = 0, \quad i = 0,1,\dots,j.$$

In fact, we can prove

$$\overline{N}^{(i)}(h) = h^{j-i}\widetilde{N}_i\big(\sqrt{h}\big), \quad i = 0,1,\dots,j, \tag{2.57}$$

by induction in i, where $\widetilde{N}_i(r)$ is C^∞ in r and $\widetilde{N}_i(0) = 0$.

First, it is not hard to see that

$$N^{(i)}(r) = r^{2j-i}N_i(r), \quad N_i \in C^\infty, \qquad N_i(0) = 0, \quad i = 0,1,\dots,2j.$$

Hence, (2.57) holds for $i = 0$. That is,

$$\overline{N}(h) = h^j N_0\big(\sqrt{h}\big) = h^j \widetilde{N}_0\big(\sqrt{h}\big).$$

It then follows that

$$\big(\overline{N}(h)\big)' = h^{j-1}\left[jN_0\big(\sqrt{h}\big) + \frac{1}{2}\sqrt{h}N_0'\big(\sqrt{h}\big)\right].$$

Let

$$\widetilde{N}_1(r) = jN_0(r) + \frac{1}{2}rN_0'(r).$$

Then $\widetilde{N}_1 \in C^\infty$ and $\widetilde{N}_1(0) = 0$. Thus, (2.57) holds for $i = 1$. Let (2.57) hold for $i = k$. Then we have

$$\overline{N}^{(k+1)}(h) = \big[h^{j-k}\widetilde{N}_k\big(\sqrt{h}\big)\big]' = h^{j-k-1}\left[(j-k)\widetilde{N}_k\big(\sqrt{h}\big) + \frac{1}{2}\sqrt{h}\widetilde{N}_k'\big(\sqrt{h}\big)\right].$$

Set

$$\widetilde{N}_{k+1}(r) = (j-k)\widetilde{N}_k(r) + \frac{1}{2}r\widetilde{N}_k'(r).$$

It follows that (2.57) holds for $i = k+1$. Hence, (2.57) has been proved.

By (2.57) it is immediate that $\overline{N} \in C^j$ for $0 \leqslant h \ll 1$. Let

$$\overline{M}(h) = \sum_{i=1}^{j} A_i h^i + \overline{N}(h).$$

Then $\overline{M} \in C^j$. Therefore $\overline{M} \in C^\infty$ since j is arbitrarily large.

Note that by (2.46) and (2.56) we have

$$\overline{M}(h) = M^*\big(\sqrt{h}\big) = 2\sqrt{h}R_0\big(\sqrt{h}, \delta\big) = M(h, \delta).$$

Thus, $M \in C^\infty$ in h at $h = 0$, and if (2.54) holds, then

$$R_0(r, \delta) = \frac{1}{2}B_k(\delta)r^{2k+1} + \mathrm{O}\big(r^{2k+3}\big).$$

By (2.53) and (2.55) and Lemma 2.7, Eq. (2.43) has a limit cycle near the origin if and only if F has two zeros correspondingly with one positive and the other negative. Hence, by Rolle theorem, (2.54) ensures that at most k limit cycles can appear near the origin for $|\varepsilon|$ small and δ in a neighborhood of D_0.

Finally, if (2.43) is analytic, then (2.51) is analytic. Hence the functions R_0 and M^* are also analytic. This implies that the series

$$M^*(r) = \sum_{i \geqslant 1} A_i r^{2j}$$

is convergent for $|r|$ small. Therefore M is analytic since $M(h, \delta) = M^*(\sqrt{h})$. The proof is completed. □

By Theorem 2.6, for any $k \geqslant 1$ we have the following expansion for M:

$$M(h, \delta) = h\bigl[b_0(\delta) + b_1(\delta)h + \cdots + b_k(\delta)h^k + \mathrm{O}\bigl(h^{k+1}\bigr)\bigr], \quad 0 < h \ll 1. \tag{2.58}$$

We can use the coefficients $b_0, b_1, \ldots, b_k$ to study the Hopf bifurcation of limit cycles.

COROLLARY 2.2. *Suppose that there exist $k \geqslant 1$, $\delta_0 \in D$ such that $b_k(\delta_0) \neq 0$ and*

$$b_j(\delta_0) = 0, \quad j = 0, 1, \ldots, k-1, \qquad \det \frac{\partial(b_0, \ldots, b_{k-1})}{\partial(\delta_1, \ldots, \delta_k)}(\delta_0) \neq 0, \tag{2.59}$$

where $\delta = (\delta_1, \ldots, \delta_m)$, $m \geqslant k$. Then for any $\varepsilon_0 > 0$ and any neighborhood V of the origin there exist $0 < \varepsilon < \varepsilon_0$ and $|\delta - \delta_0| < \varepsilon_0$ such that (2.43) *has precisely k limit cycles in V.*

PROOF. Fix $\delta_j = \delta_{j0}$ for $j = k+1, \ldots, m$. By (2.59) the change of parameters

$$b_j = b_j(\delta), \quad j = 0, \ldots, k-1$$

has the inverse $\delta_j = \delta_j(b_0, \ldots, b_{k-1})$, $j = 1, \ldots, k$. Then (2.58) becomes

$$M(h, \delta) = h\bigl[b_0 + b_1 h + \cdots + b_{k-1}h^{k-1} + b_k h^k + \mathrm{O}\bigl(h^{k+1}\bigr)\bigr]$$

where $b_k = b_k(\delta_0) \neq 0$ as $b_0 = \cdots = b_{k-1} = 0$. By changing the sign of $b_{k-1}, b_{k-2}, \ldots, b_0$ in turn such that

$$b_{j-1}b_j < 0, \quad j = k, k-1, \ldots, 1, \qquad 0 < |b_0| \ll |b_1| \ll \cdots \ll |b_{k-1}| \ll 1,$$

we can find k simple positive zeros $h_1, h_2, \ldots, h_k$ with $0 < h_k < h_{k-1} < \cdots < h_1 \ll 1$. Let $r_j = \sqrt{h_j}$, $j = 1, \ldots, k$. Then $r_1, \ldots, r_k$ are simple positive zeros of $R_0(r, \delta)$. By (2.55) and the implicit function theorem, the function F has k zeros $r_j + \mathrm{O}(\varepsilon)$, $j = 1, \ldots, k$. This ends the proof. □

The following is evident from Theorem 2.6(ii).

COROLLARY 2.3. *If for any* $\varepsilon_0 > 0$ *and any neighborhood* V *of the origin* (2.43) *has* k *limit cycles in* V *for some* (ε, δ) *satisfying* $0 < |\varepsilon| < \varepsilon_0$, $|\delta - \delta_0| < \varepsilon_0$, *then* $M(h, \delta_0) = \mathrm{O}(h^{k+1})$.

In the multiple parameter case it often occurs that $M(h, \delta_0) \equiv 0$, $M(h, \delta) \not\equiv 0$ for $\delta \neq \delta_0$. In this case (2.54) fails to hold, and we have further the following result.

THEOREM 2.7. *Let* (2.44) *hold. Suppose*

(i) *the coefficients* $b_0, \ldots, b_{k-1}$ *in* (2.58) *satisfy* (2.59);

(ii) *there exists a* k*-dimensional vector function* $\varphi(\varepsilon, \delta_{k+1}, \ldots, \delta_m)$ *such that* (2.43) *has a center at the origin when* $(\delta_1, \ldots, \delta_k) = \varphi(\varepsilon, \delta_{k+1}, \ldots, \delta_m)$ *for* $|\varepsilon| + |\delta - \delta_0|$ *small.*

Then there exist $\varepsilon_0 > 0$ *and a neighborhood* V *of the origin such that* (2.43) *has at most* $k - 1$ *limit cycles in* V *for* $0 < |\varepsilon| < \varepsilon_0$, $|\delta - \delta_0| < \varepsilon_0$. *Moreover,* $k - 1$ *limit cycles can appear in an arbitrary neighborhood of the origin for some* (ε, δ) *sufficiently near* $(0, \delta_0)$.

PROOF. By (2.58) and noting that $M(h, \delta) = 2rR_0(r, \delta)$, $r = \sqrt{h}$, we have

$$R_0(r, \delta) = r\left[\sum_{j=0}^{k} b_j(\delta) r^{2j} + \mathrm{O}\big(r^{2k+2}\big)\right].$$

Then the function F in (2.55) has the following expansion:

$$F(r, \varepsilon, \delta) = \sum_{j=0}^{2k-1} c_j(\varepsilon, \delta) r^j + r^{2k} Q(r, \varepsilon, \delta), \tag{2.60}$$

where $Q \in C^\infty$, and

$$c_{2j}(0, \delta) = b_j(\delta), \quad c_{2j+1}(0, \delta) = 0, \quad j = 0, \ldots, k - 1.$$

By (2.59), the equations

$$b_j = c_{2j}(\varepsilon, \delta), \quad j = 0, \ldots, k - 1$$

have the solution

$$(\delta_1, \ldots, \delta_k) = \bar{\varphi}(\varepsilon, b_0, \ldots, b_{k-1}, \delta_{k+1}, \ldots, \delta_m). \tag{2.61}$$

By condition (ii) we have $F(r, \varepsilon, \delta) = 0$ and hence $c_{2j}(\varepsilon, \delta) = 0$, $j = 0, \ldots, k - 1$ as long as $(\delta_1, \ldots, \delta_k) = \varphi(\varepsilon, \delta_{k+1}, \ldots, \delta_m)$. The uniqueness of the solution $\bar{\varphi}$ implies that

$$\bar{\varphi} = \varphi \quad \text{if and only if} \quad b_0 = \cdots = b_{k-1} = 0. \tag{2.62}$$

Inserting (2.61) into (2.60) we obtain

$$\begin{aligned} F &= \sum_{j=0}^{k-1}\big[b_j r^{2j} + c_{2j+1}(\varepsilon,\bar{\varphi},\delta_{k+1},\dots,\delta_m)r^{2j+1}\big] + r^{2k}Q(r,\varepsilon,\bar{\varphi},\delta_{k+1},\dots,\delta_m) \\ &\equiv \widetilde{F}\big(r,\varepsilon,\tilde{\delta}\big), \quad \tilde{\delta} = (b_0,\dots,b_{k-1},\delta_{k+1},\dots,\delta_m). \end{aligned} \tag{2.63}$$

It follows from (2.61) and (2.62) that $\widetilde{F} = 0$ as $b_j = 0$, $j = 0,\dots,k-1$. Hence, by the mean value theorem we can write

$$c_{2j+1}(\varepsilon,\bar{\varphi},\delta_{k+1},\dots,\delta_m) = \varepsilon\sum_{i=0}^{k-1} b_i A_{ij}\big(\varepsilon,\tilde{\delta}\big),$$

$$Q(r,\varepsilon,\bar{\varphi},\delta_{k+1},\dots,\delta_m) = \sum_{i=0}^{k-1} b_i Q_i\big(r,\varepsilon,\tilde{\delta}\big),$$

where $Q_i \in C^\infty$, $i = 0,\dots,k-1$. Note that $\varepsilon r^2 F = r(P_1 - r)$ keeps sign for $0 < |r| \ll 1$ by Lemma 2.1 and (2.53). By (2.63), it follows that

$$c_{2j+1}(\varepsilon,\bar{\varphi},\delta_{k+1},\dots,\delta_m) = 0, \quad \text{if } b_0 = \cdots = b_j = 0,\ j = 0,\dots,k-1.$$

This yields that

$$A_{ij} = 0, \quad j+1 \leqslant i \leqslant k-1,\ j = 0,\dots,k-2.$$

Therefore, the function $\widetilde{F}$ in (2.63) can be written as

$$\widetilde{F}\big(r,\varepsilon,\tilde{\delta}\big) = \sum_{j=0}^{k-1} b_j r^{2j} P_j\big(r,\varepsilon,\tilde{\delta}\big), \tag{2.64}$$

where

$$P_j = 1 + \varepsilon\sum_{i=j}^{k-1} A_{ji}\big(\varepsilon,\tilde{\delta}\big)\, r^{2(i-j)+1} + r^{2(k-j)} Q_j, \quad 0 \leqslant j \leqslant k-1.$$

We particularly have

$$\widetilde{F}\big(r,\varepsilon,\tilde{\delta}\big) = \sum_{j=0}^{k-1} b_j r^{2j} + \mathrm{O}\big(|r|^{2k} + |\varepsilon|\big).$$

By using this form we can prove, in a similar manner to Corollary 2.2, that $k-1$ limit cycles can appear in an arbitrary neighborhood of the origin for some (ε,δ) sufficiently close to $(0,\delta_0)$.

It needs only to prove that $\widetilde{F}$ has at most $k-1$ positive zeros near $r=0$ for $|b_0|+\cdots+|b_{k-1}|>0$ small. We do this by induction in k. For convenience, denote by F_{k-1} the right-hand side function of (2.64).

First, for $k=1$, we have

$$F_0 = b_0 P_0 = b_0\big(1+\mathrm{O}\big(|\varepsilon|+|r|\big)\big) \neq 0 \quad \text{for } |b_0|>0.$$

Suppose for $k=n$ the function

$$F_{n-1} = \sum_{j=0}^{n-1} b_j r^{2j} P_j$$

has at most $n-1$ positive zeros in r near $r=0$ for $|\varepsilon|$ and $|b_0|+\cdots+|b_{n-1}|>0$ small, where $P_j = 1+\mathrm{O}(|\varepsilon|+|r|) \in C^\infty$, $j=0,\ldots,n-1$. Consider the function

$$F_n = \sum_{j=0}^{n} b_j r^{2j} P_j,$$

where $P_j = 1+\mathrm{O}(|\varepsilon|+|r|) \in C^\infty$. We have

$$F_n = P_0 \widetilde{F}_n, \quad \widetilde{F}_n = \sum_{j=0}^{n} b_j r^{2j} \widetilde{P}_j,$$

where $\widetilde{P}_0 = 1$, $\widetilde{P}_j = P_j/P_0 = 1+\mathrm{O}(|\varepsilon|+|r|) \in C^\infty$, $j=1,\ldots,n$. Then

$$\frac{\mathrm{d}\widetilde{F}_n}{\mathrm{d}r} = \sum_{j=1}^{n} 2jb_j r^{2j-1}\left(\widetilde{P}_j + \frac{r}{2}\frac{\mathrm{d}\widetilde{P}_j}{\mathrm{d}r}\right) = r\sum_{j=0}^{n-1} \bar{b}_j r^{2j} \overline{P}_j = r\overline{F}_{n-1},$$

where

$$\bar{b}_j = 2(j+1)b_{j+1}, \quad \overline{P}_j = \widetilde{P}_{j+1} + \frac{r}{2}\frac{\mathrm{d}\widetilde{P}_{j+1}}{\mathrm{d}r} = 1+\mathrm{O}\big(|\varepsilon|+|r|\big) \in C^\infty.$$

By the induction assumption, the function $\overline{F}_{n-1}$ has at most $n-1$ positive zeros in r near $r=0$ for $|\varepsilon|$ and $|\bar{b}_0|+\cdots+|\bar{b}_{n-1}|>0$ small. Hence, by Rolle's theorem it follows that $\widetilde{F}_n$ has at most n positive zeros near $r=0$ in r for $|\varepsilon|$ and $|b_0|+\cdots+|b_n|>0$ small. This finishes the proof. □

Observe that in both Theorems 2.6 and 2.7 the parameter δ is required to vary near δ_0. The results are local in this sense. In many cases the functions p and q in (2.43) depend on δ linearly. This enables us to obtain a global result based on Theorems 2.6 and 2.7 as follows.

THEOREM 2.8. *Let* (2.44) *hold, and let the functions* p *and* q *in* (2.43) *be linear in* δ. *Suppose further that for an integer* $k \geqslant 1$

(i) $\operatorname{rank} \dfrac{\partial(b_0, \ldots, b_{k-1})}{\partial(\delta_1, \ldots, \delta_m)} = k,\ m \geqslant k$;

(ii) *Eq.* (2.43) *has a center at the origin as* $b_j(\delta) = 0,\ j = 0, 1, \ldots, k-1$.

Then for any given $N > 0$, *there exist* $\varepsilon_0 > 0$ *and a neighborhood* V *of the origin such that Eq.* (2.43) *has at most* $k-1$ *limit cycles in* V *for* $0 < |\varepsilon| < \varepsilon_0$, $|\delta| \leqslant N$. *Moreover,* $k-1$ *limit cycles can appear in an arbitrary neighborhood of the origin for some* (ε, δ).

PROOF. Since p and q are linear in δ, each coefficient b_j in (2.58) is also linear in δ. Hence, by condition (i) we can suppose

$$\det \frac{\partial(b_0, \ldots, b_{k-1})}{\partial(\delta_1, \ldots, \delta_k)} \neq 0.$$

It follows that the equations $b_j(\delta) = 0,\ j = 0, \ldots, k-1$ have a solution $(\delta_1, \ldots, \delta_k) = \varphi(\delta_{k+1}, \ldots, \delta_m)$.

For $\delta_0^* = (\varphi(0), 0) \in \mathbb{R}^m$, by Theorem 2.7, Eq. (2.43) can have $k-1$ limit cycles near the origin for some (ε, δ) near $(0, \delta_0^*)$. Then we need to prove that $k-1$ is the maximal number of limit cycles. If it is not the case, then there exist $N > 0$ and sequences $\varepsilon_n \to 0$, $\delta^{(n)} \in \mathbb{R}^m$ with $|\delta^{(n)}| \leqslant N$ such that for $(\varepsilon, \delta) = (\varepsilon_n, \delta^{(n)})$ Eq. (2.43) has k limit cycles which approach the origin as $n \to \infty$. We may suppose $\delta^{(n)} \to \delta_0$ for some $\delta_0 \in \mathbb{R}^m$ as $n \to \infty$. First, by Theorem 2.6 we must have $b_j(\delta_0) = 0,\ j = 0, \ldots, k-1$. By our assumption (ii), Eq. (2.43) has a center at the origin for $(\delta_1, \ldots, \delta_k) = \varphi(\delta_{k+1}, \ldots, \delta_m)$. Hence, it follows from Theorem 2.7 that (2.43) has at most $k-1$ limit cycles near the origin for all (ε, δ) sufficiently close to $(0, \delta_0)$. This is a contradiction since Eq. (2.43) has k limit cycles approaching the origin as $(\varepsilon, \delta) = (\varepsilon_n, \delta^{(n)}) \to (0, \delta_0)$. This ends the proof. □

Theorems 2.5 and 2.6 tell us that the coefficients in the expansion of M act like focus values. The following lemma gives a relation between the two groups of the values.

LEMMA 2.9. *Let* (2.44) *and* (2.58) *hold. Then*

$$b_0 = 4\pi v_1^*, \qquad b_j = \frac{4\pi}{K^j}\left[v_{2j+1}^* + \mathrm{O}\left(\left|v_1^*, v_3^*, \ldots, v_{2j-1}^*\right|\right)\right], \quad j = 1, \ldots, k-1,$$

where

$$v_{2j+1}^* = \frac{\partial v_{2j+1}}{\partial \varepsilon}\bigg|_{\varepsilon=0}, \quad j = 0, \ldots, k-1,$$

and v_{2j+1} *is the* j*th Lyapunov constant of* (2.43) *at the origin.*

PROOF. Let $P(r, \varepsilon, \delta)$ denote the Poincaré map of (2.43). Then the point B in (2.45) is given by $(P(a, \varepsilon, \delta), 0)$, where $a = \sqrt{\frac{h}{K}}(1 + \mathrm{O}(\sqrt{h}))$. Note that $P - a = \mathrm{O}(|\varepsilon a|)$. By the mean value theorem we have

$$\begin{aligned} H(B)-H(A) &= H_x\big(a\big(1+\mathrm{O}(\varepsilon)\big),0\big)(P-a) \\ &= 2Ka\big[1+\mathrm{O}\big(|\varepsilon|+|a|\big)\big](P-a). \end{aligned}$$

By (2.39) and (2.40) we can write formally

$$P(a,\varepsilon,\delta)-a = 2\pi\sum_{i\geqslant 0} v_{2i+1}a^{2i+1}P_i,$$

where $P_i = 1+\mathrm{O}(a)$, $i\geqslant 0$. Hence

$$H(B)-H(A) = 4\pi h\sum_{i\geqslant 0}\frac{v_{2i+1}}{K^i}h^i\overline{P}_i,$$

where $\overline{P}_i = 1+\mathrm{O}(|\varepsilon|+\sqrt{h})$, $i\geqslant 0$. Inserting the above into (2.45) and noting $v_{2i+1} = \varepsilon v^*_{2i+1}+\mathrm{O}(\varepsilon^2)$ we obtain

$$4\pi h\sum_{i\geqslant 0}\frac{v^*_{2i+1}}{K^i}h^i\big(1+\mathrm{O}\big(\sqrt{h}\big)\big) = M(h,\delta).$$

Since M is C^∞ at $h=0$ it follows from the above that

$$M(h,\delta) = 4\pi h\bigg[v_1^* + \frac{1}{K}\big(v_3^*+O\big(v_1^*\big)\big)h + \frac{1}{K^2}\big(v_5^*+\mathrm{O}\big(v_1^*,v_3^*\big)\big)h^2+\cdots\bigg].$$

Thus the conclusion follows by comparing with (2.58). This completes the proof. □

EXAMPLE 2.6. Consider

$$\begin{aligned} \dot{x} &= y-\big(\mu_0x^5+\mu_1x^3+\mu_2x\big), \\ \dot{y} &= -x. \end{aligned} \tag{2.65}$$

We claim that there exist $\varepsilon_0>0$ and a neighborhood V of the origin such that (2.65) has at most 2 limit cycles in V for $|\mu_0|+|\mu_1|+|\mu_2|<\varepsilon_0$, and 2 limit cycles can appear.

In fact, by the discussion to (2.41) we know that

$$\begin{aligned} &v_1 = -\frac{1}{2}\mu_2+\mathrm{O}\big(\mu_2^2\big), \qquad v_3 = -\frac{3}{8}\mu_1+\mathrm{O}(\mu_2), \\ &v_5 = -\frac{5}{16}\mu_0+\mathrm{O}\big(|\mu_1|+|\mu_2|\big). \end{aligned}$$

Let $\mu_i=\varepsilon\delta_i$, $\varepsilon=\sqrt{\mu_0^2+\mu_1^2+\mu_2^2}$, $\delta_0^2+\delta_1^2+\delta_2^2=1$. Then by Lemma 2.9 (taking $\mu=1$ and $K=1/2$) we have

$$b_0=-2\pi\delta_2, \qquad b_1=-3\pi\delta_1+\mathrm{O}(\delta_2), \qquad b_2=-5\pi\delta_0+\mathrm{O}\big(|\delta_1|+|\delta_2|\big).$$

For the sake of convenience, we take $\delta_0, \delta_1, \delta_2$ as free parameters with $|\delta_i| \leqslant 1$. Then the conditions of Theorem 2.8 are satisfied with $m = k = 3$. Therefore, the claim follows.

Note that for $\varepsilon = 0$ the origin is a linear center of (2.65). Hence, in this case the function M can be obtained directly by using (2.46).

DEFINITION 2.4. We say that Eq. (2.43) has Hopf cyclicity $k - 1$ at the origin if the conclusion of Theorem 2.8 holds.

Thus, both systems (2.41) and (2.65) have Hopf cyclicity 2 at the origin.

EXAMPLE 2.7. Consider a Liénard system of the form

$$\dot{x} = y - \varepsilon \sum_{i=1}^{2n+1} a_i x^i, \qquad \dot{y} = -x \tag{2.66}$$

where $n \geqslant 1$, $|a_i| \leqslant 1$, and $\varepsilon > 0$ is small. We claim that the system has Hopf cyclicity n at the origin.

In fact, we have $H(x, y) = \frac{1}{2}(x^2 + y^2)$ with $\mu = 1$, $K = \frac{1}{2}$. The curve L_h given by $H(x, y) = h$ has the representation $(x, y) = \sqrt{2h}(\cos t, -\sin t)$. Hence, by (2.46) we have

$$M(h) = -\sum_{j=0}^{n} 2^{j+1} N_j a_{2j+1} h^{j+1},$$

where

$$N_j = \int_0^{2\pi} \cos^{2(j+1)} t \, \mathrm{d}t > 0.$$

Set $\delta = (a_1, a_2, \ldots, a_{2n+1})$, $b_j = -2^{j+1} N_j a_{2j+1}$, $j = 0, \ldots, n$ and $k = n + 1$. Note that by Theorem 2.3(i) Eq. (2.66) has a center at the origin as $b_j = 0$, $j = 0, \ldots, n$. Thus, the claim follows from Theorem 2.8.

In the proof of Corollary 2.2 we have given a way to find limit cycles near the origin. In the case of (2.66), $M(h)$ can have n zeros $h_1 > h_2 > \cdots > h_n > 0$ for some $(a_1, a_3, \ldots, a_{2n+1})$. Then the corresponding function F in (2.55) has n zeros $\sqrt{h_j} + \mathrm{O}(\varepsilon)$, $j = 1, \ldots, n$. It follows that the n limit cycles of (2.66) approach the curves $\frac{1}{2}(x^2 + y^2) = h_j$, $j = 1, \ldots, n$, respectively, as $\varepsilon \to 0$.

In the following we give another way to obtain limit cycles near the origin. For convenience, take $a_{2j} = 0$, $j = 1, \ldots, n$.

First, from Lemma 2.9, we have

$$v_{2j+1} = \varepsilon v_{2j+1}^* + \mathrm{O}(\varepsilon^2), \quad j = 0, \ldots, n,$$

where

$$v_1^* = \frac{1}{4\pi} b_0 = -\frac{N_0}{2\pi} a_1,$$
$$v_{2j+1}^* = \frac{1}{2^{j+2}\pi} b_j + \mathrm{O}\big(|b_0, \ldots, b_{j-1}|\big) = -\frac{N_j}{2\pi} a_{2j+1} + \mathrm{O}\big(|a_1, a_3, \ldots, a_{2j-1}|\big).$$

On the other hand, for $\widetilde{V} = x^2 + y^2$ we have along the orbit of (2.66)

$$\dot{\widetilde{V}} = -2\varepsilon \sum_{j=0}^{n} a_{2j+1} x^{2j+2}.$$

By Corollary 2.1, it holds that

$$\widetilde{L}_{k+1} = -\frac{\varepsilon}{\pi} a_{2k+1} N_k$$

if $a_{2j+1} = 0$ for $j = 0, \ldots, k-1$. It then follows that

$$v_{2j+1} = -\varepsilon \left[\frac{N_j}{2\pi} a_{2j+1} + \mathrm{O}\big(|a_1, a_3, \ldots, a_{2j-1}|\big) \right] \big(1 + \mathrm{O}(\varepsilon)\big), \quad j = 0, \ldots, n.$$

For $\varepsilon > 0$, let us vary $a_1, a_3, \ldots, a_{2n+1}$ such that

$$a_{2j-1} a_{2j+1} < 0, \qquad 0 < |a_{2j-1}| \ll |a_{2j+1}| \ll \varepsilon, \quad j = 1, \ldots, n$$

which yields

$$v_{2j-1} v_{2j+1} < 0, \qquad 0 < |v_{2j-1}| \ll |v_{2j+1}| \ll \varepsilon^2, \quad j = 1, \ldots, n.$$

Thus, by (2.32), the corresponding function $P(r) - r$ will have n zeros which give n limit cycles of (2.66). Geometrically, the n limit cycles are obtained by changing the stability of the origin n times. Moreover, unlike above they approach the origin as $\varepsilon \to 0$.

REMARK 2.3. There are different ways to prove Lemma 2.3 for the normal form system (2.11). Here the proof is given by following [111]. The conclusions in Lemmas 2.4 and 2.6 are well known. However, the definite relationship between constants a_m, v_{2m+1} and L_m given in the lemmas appears for the first time here. For more discussions on the level set of a Hamiltonian system, the reader can consult [36]. On the bifurcation of limit cycles, Theorems 2.4 and 2.5 are basic tools, while Theorems 2.6–2.8 were recently obtained by [47]. More discussions similar to Lemma 2.9 can be found in [80]. Under condition (2.44), it was proved in [64] that the right-hand side function in (2.45) is C^∞ in $\sqrt{h}$ at $h = 0$, but not C^2 in h at $h = 0$ generally.

As we know, in 1901, Hilbert [73] posed 23 mathematical problems of which the second part of the 16th one is to find the maximal number and relative position of limit cycles of planar polynomial systems. Many works have been done on the study of the problem, especially for quadratic and cubic systems, see [3,4,8,10–13,15,18–34,38–51,54–72,74–110, 113–126,128,129]. A detailed introduction and related literatures can be found in Li [85], Schlomiuk [109] and Ilyashenko [78]. As was showed in Examples 2.4 and 2.7, a typical way to find limit cycles in Hopf bifurcation is to compute focal values and change the stability of the focus by using the values. Certain nice results have been obtained for quadratic and cubic systems. Bautin [5] proved that a focus of a quadratic system has order at most three and that for this system a focus or center can generate at most three limit cycles under perturbations of its coefficients. Then Chen and Wang [12] (by bifurcation method) and Shi [110] (by using Poincaré–Bendixson theorem) separately found a quadratic system having four limit cycles. More and more mathematicians believe that quadratic system have at most four limit cycles. However, up to now the problem is still open. Li and Li [89], Li and Huang [88], Li and Liu [91–93], and Liu, Yang and Jiang [96] found different cubic systems having eleven limit cycles by using Melnikov function method. James and Lloyd [79] gave a cubic system having eight limit cycles in a neighborhood of a focus. Recently, Han, Lin and Yu [60] and Yu and Han [120,121] obtained sufficient conditions for a cubic system to have 10 or 12 limit cycles, respectively (all limit cycles having small amplitude). It seems that the maximal number of limit cycle for cubic system is 12.

For Hopf bifurcation in higher dimension, the reader can see Hale [35], Chow and Hale [16], Chow, Li and Wang [17] and Han [51] etc. For bifurcation of periodic solutions of delay-differential equations, see [7,37,52,53] et al.

3. Perturbations of Hamiltonian systems

3.1. *General theory*

In this section we will study a C^∞ system of the form

$$\dot{x} = H_y + \varepsilon p(x, y, \varepsilon, \delta), \qquad \dot{y} = -H_x + \varepsilon q(x, y, \varepsilon, \delta), \tag{3.1}$$

where $H(x, y), p(x, y, \varepsilon, \delta), q(x, y, \varepsilon, \delta)$ are C^∞ functions, $\varepsilon \geqslant 0$ is small and $\delta \in D \subset \mathbb{R}^m$ is a vector parameter with D compact. For $\varepsilon = 0$ (3.1) becomes

$$\dot{x} = H_y, \qquad \dot{y} = -H_x \tag{3.2}$$

which is Hamiltonian. Hence, Eq. (3.1) is called a near-Hamiltonian system.

For Eq. (3.2) we suppose there exist a family of periodic orbits given by

$$L_h\colon\ H(x, y) = h, \quad h \in (\alpha, \beta)$$

such that L_h approaches an elementary center point, denoted by L_α, as $h \to \alpha$, and an invariant curve, denoted by L_β, as $h \to \beta$. Without loss of generality, we can assume that each L_h is oriented clockwise.

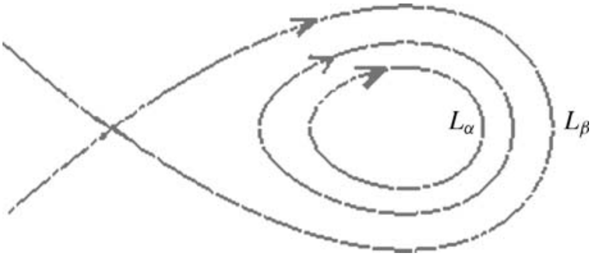

Fig. 9. The phase portrait of (3.2) with a L_β homoclinic loop.

If L_β is bounded, it usually is a homoclinic loop consisting of a saddle and a connection or a heteroclinic loop consisting of at least two saddles and connections between them. In the homoclinic case, the phase portrait of the family $\{L_h\colon \alpha \leqslant h \leqslant \beta\}$ is given in Fig. 9.

Introduce an open set G as follows:

$$G = \bigcup_{\alpha<h<\beta} L_h.$$

Our main purpose is to study the number of limit cycles of Eq. (3.1) in a neighborhood of the closure $\overline{G}$ of G for $\varepsilon > 0$ small and $\delta \in D$.

Note that if Eq. (3.1) has a limit cycle $L(\varepsilon, \delta)$ for $\varepsilon > 0$ small and $\delta \in D_0 \subset D$, then the limit of the cycle as $\varepsilon \to 0$ is either the center L_α, a periodic orbit L_h with $h \in (\alpha, \beta)$ or the boundary L_β. That is,

$$\lim_{\varepsilon\to 0} L(\varepsilon, \delta) = L_h, \qquad h \in [\alpha, \beta].$$

In this case, we say that the limit cycle $L(\varepsilon, \delta)$ is generated from L_h. Thus, in order to study the number of limit cycles, we first need to study the number of limit cycles generated from each L_h.

For the purpose, similar to Definition 2.4 we first introduce a notation below.

DEFINITION 3.1. We say that Eq. (3.1) has *cyclicity* k at a given L_h, $h \in [\alpha, \beta]$, if there exist $\varepsilon_0 > 0$ and a neighborhood V of L_h such that Eq. (3.1) has at most k limit cycles in V for $0 < \varepsilon < \varepsilon_0$, $\delta \in D$ and if k limit cycles can appear in an arbitrary neighborhood of L_h for some (ε, δ) with $\varepsilon > 0$ sufficiently small. More specifically, k is said to be *Hopf* (*Poincaré or homoclinic*) *cyclicity* when $h = \alpha$ ($h \in (\alpha, \beta)$ or $h = \beta$ with L_β being a homoclinic loop).

In the last section we gave some method to find Hopf cyclicity. This section concerns with global bifurcations of limit cycles and presents further methods to find Hopf, Poincaré and homoclinic cyclicity.

Take $h = h_0 \in (\alpha, \beta)$ and $A(h_0) \in L_{h_0}$. Let l be a cross section of Eq. (3.2) passing through $A(h_0)$. Then for h near h_0 the periodic orbit L_h has a unique intersection point with l, denoted by $A(h)$. That is, $A(h) = L_h \cap l$. Consider the positive orbit $\gamma(h, \varepsilon, \delta)$

of Eq. (3.1) starting at $A(h)$. Let $B(h,\varepsilon,\delta)$ denote the first intersection point of the orbit with l. Then similar to (2.45) we have

$$H(B)-H(A)=\varepsilon\bigl[M(h,\delta)+\mathrm{O}(\varepsilon)\bigr]=\varepsilon F(h,\varepsilon,\delta), \tag{3.3}$$

where

$$\begin{aligned} M(h,\delta)&=\oint_{L_h}(H_y q+H_x p)|_{\varepsilon=0}\,\mathrm{d}t\\ &=\oint_{L_h}(q\,\mathrm{d}x-p\,\mathrm{d}y)|_{\varepsilon=0}=\iint_{H\leqslant h}(p_x+q_y)|_{\varepsilon=0}\,\mathrm{d}x\,\mathrm{d}y. \end{aligned} \tag{3.4}$$

The function $F(h,\varepsilon,\delta)$ in (3.3) is called a bifurcation function of Eq. (3.1). It has the following property.

LEMMA 3.1. *For $\varepsilon>0$ small and $\delta\in D$, Eq.* (3.1) *has a limit cycle near L_{h_0}, $h_0\in(\alpha,\beta)$, if and only if the equation $F(h,\varepsilon,\delta)=0$ has a zero in h near h_0.*

PROOF. Since the orbit $\gamma(h,\varepsilon,\delta)$ starting at $A(h)$ is closed if and only if $A=B$, we need only to prove that $A=B$ if and only if $H(A)=H(B)$ by (3.3). It is easy to see that $B=A+\mathrm{O}(\varepsilon)$. Hence, by Taylor formula for $\varepsilon>0$ small we have

$$H(B)-H(A)=\bigl(H_x(A),H_y(A)\bigr)\cdot(B-A)+\mathrm{O}\bigl(|B-A|^2\bigr).$$

Note that the cross section l can be taken to be parallel to the gradient $(H_x(A),H_y(A))$. It follows that

$$H(B)-H(A)=\Bigl[\pm\sqrt{H_x^2(A)+H_y^2(A)}+\mathrm{O}\bigl(|B-A|\bigr)\Bigr]\cdot|B-A|,$$

which gives the desired conclusion. The proof is completed. ☐

As in the situation of Hopf bifurcation, the Melnikov function $M(h,\delta)$ can also be used to determine the cyclicity at a periodic orbit. First, by (3.3) we have

THEOREM 3.1. *Let $h_0\in(\alpha,\beta)$, $\delta_0\in D$.*

(i) *There is no limit cycle near L_{h_0} for $\varepsilon+|\delta-\delta_0|$ small if $M(h_0,\delta_0)\neq 0$.*

(ii) *There is exactly one* (*at least one*, *respectively*) *limit cycle $L(\varepsilon,\delta)$ for $\varepsilon+|\delta-\delta_0|$ small which approaches L_{h_0} as $(\varepsilon,\delta)\to(0,\delta_0)$ if $M(h_0,\delta_0)=0$, $M_h(h_0,\delta_0)\neq 0$* (*h_0 is a zero of $M(h,\delta_0)$ with odd multiplicity*, *respectively*).

(iii) *The cyclicity of Eq.* (3.1) *at L_{h_0} is at most k if for any $\delta\in D$ there exists $0\leqslant j\leqslant k$ such that*

$$M_h^{(j)}(h_0,\delta)\neq 0.$$

PROOF. By (3.3) and Lemma 3.1, the first conclusion is clear. For the second one, the conclusion follows from the implicit function theorem if h_0 is a simple zero of $M(h, \delta_0)$. Let h_0 be a multiple zero of $M(h, \delta_0)$ with odd multiplicity. Then for $\varepsilon_0 > 0$ small we have

$$M(h_0 - \varepsilon_0, \delta_0) \cdot M(h_0 + \varepsilon_0, \delta_0) < 0.$$

Hence, by (3.3) we have

$$F(h_0 - \varepsilon_0, \varepsilon, \delta) \cdot F(h_0 + \varepsilon_0, \varepsilon, \delta) < 0$$

for $0 < \varepsilon < \varepsilon_0$, $|\delta - \delta_0| < \varepsilon_0$ as long as ε_0 is sufficiently small. Thus the function $F(h, \varepsilon, \delta)$ has a zero $h^* \in (h_0 - \varepsilon_0, h_0 + \varepsilon_0)$.

For the third conclusion, if Eq. (3.1) has cyclicity at least $k + 1$ at L_{h_0}, then there exist some $\varepsilon_n \to 0$, $\delta^{(n)} \in D$ such that for $(\varepsilon, \delta) = (\varepsilon_n, \delta^{(n)})$ Eq. (3.1) has at least $k + 1$ limit cycles which approach L_{h_0} as $n \to \infty$. We can suppose $\delta^{(n)} \to \delta_0$ as $n \to \infty$. On the other hand, by our assumption $M(h, \delta_0)$ has h_0 as a zero of multiplicity at most k. By (3.3) and Rolle's theorem for $\varepsilon + |\delta - \delta_0|$ small the function $F(h, \varepsilon, \delta)$ has at most k zeros in h near h_0, which follows that at most k limit cycles exist near L_{h_0} for $\varepsilon + |\delta - \delta_0|$ small. Thus a contradiction appears if $(\varepsilon, \delta) = (\varepsilon_n, \delta^{(n)})$ with n sufficiently large.

The proof is completed. ☐

By the above proof we have immediately

COROLLARY 3.1. *Suppose for some* $\delta_0 \in D$, $M(h, \delta_0)$ *has* k *zeros in* $h \in (\alpha, \beta)$ *with each having odd multiplicity. Then for* $\varepsilon + |\delta - \delta_0|$ *small Eq.* (3.1) *has* k *limit cycles in a compact subset of the open set* G.

COROLLARY 3.2. *If there exist* $h_0 \in (\alpha, \beta), \delta_0 \in D$ *such that for an arbitrary neighborhood of* L_{h_0}, *Eq.* (3.1) *has* k *limit cycles in the neighborhood for some* (ε, δ) *with* $\varepsilon + |\delta - \delta_0|$ *sufficiently small, then* $M(h, \delta_0) = \mathrm{O}(|h - h_0|^k)$.

Let $L(\varepsilon, \delta)$ be the limit cycle appeared in Theorem 3.1. To determine its stability we need to consider the sigh of the integral

$$\varepsilon \oint_{L(\varepsilon,\delta)} (p_x + q_y)\,\mathrm{d}t = \varepsilon \left[\oint_{L_{h_0}} (p_x + q_y)|_{\varepsilon=0}\,\mathrm{d}t + \mathrm{O}(\varepsilon) \right].$$

Obviously, if

$$\sigma(h_0, \delta_0) = \oint_{L_{h_0}} (p_x + q_y)|_{\varepsilon=0,\delta=\delta_0}\,\mathrm{d}t \neq 0$$

then the stability will be determined easily. The following lemma gives a relation between $\sigma(h, \delta)$ and $M_h(h, \delta)$.

LEMMA 3.2. *Suppose L_h is oriented clockwise. Then*

$$M_h(h,\delta) = \pm \oint_{L_h} (p_x + q_y)|_{\varepsilon=0}\, \mathrm{d}t = \pm\sigma(h,\delta),$$

where "+" (respectively "−") is taken when L_h expands (respectively shrinks) with h increasing.

PROOF. Fix $h_0 \in (\alpha, \beta)$. For definiteness, suppose that L_h expands with h increasing. Then for $h > h_0$, applying Green's formula we have

$$M(h,\delta) - M(h_0,\delta) = \iint_{\Delta(h)} (p_x + q_y)|_{\varepsilon=0}\, \mathrm{d}x\, \mathrm{d}y, \tag{3.5}$$

where $\Delta(h)$ denotes the annulus bounded by L_h and L_{h_0}. Let $u(t,h)$ denote a representation of L_h satisfying

$$H\bigl(u(t,h)\bigr) = h, \quad 0 \leqslant t \leqslant T(h),\ h \in (\alpha,\beta).$$

Here $T(h)$ denotes the period of L_h. Consider the integral transformation of variables given by

$$(x,y) = u(t,r), \quad 0 \leqslant t \leqslant T(r),\ h_0 < r < h.$$

Note that

$$\mathrm{D}H(u) \cdot \mathrm{D}_r u = \det \frac{\partial u(t,r)}{\partial(t,r)} = 1.$$

We obtain from (3.5)

$$M(h,\delta) - M(h_0,\delta) = \int_{h_0}^{h} \mathrm{d}r \int_0^{T(r)} (p_x + q_y)\bigl(u(t,r), 0, \delta\bigr)\, \mathrm{d}t.$$

Then differentiating the above in h yields

$$M_h(h,\delta) = \int_0^{T(h)} (p_x + q_y)\bigl(u(t,h), 0, \delta\bigr)\, \mathrm{d}t.$$

This ends the proof. □

EXAMPLE 3.1. Consider van der Pol equation

$$\ddot{x} + \varepsilon\bigl(x^2 - 1\bigr)\dot{x} + x = 0.$$

The equation is equivalent to

$$\dot{x} = y, \qquad \dot{y} = -x - \varepsilon\big(x^2 - 1\big)y. \tag{3.6}$$

For $\varepsilon = 0$, Eq. (3.6) has periodic orbits L_h: $\frac{1}{2}(x^2 + y^2) = h$, $h > 0$. By (3.4) we have

$$M(h) = \iint_{x^2+y^2 \leqslant 2h} \big(1 - x^2\big)\,\mathrm{d}x\,\mathrm{d}y = \pi h(2 - h).$$

The function M has a unique positive zero $h = 2$. By Lemma 3.2 we have

$$\sigma_0 = \oint_{L_2} \big(1 - x^2\big)\,\mathrm{d}t = M'(2) = -2\pi.$$

Hence, by Theorem 3.1, Eq. (3.6) has a unique limit cycle $L(\varepsilon)$ for $\varepsilon > 0$ which is stable, simple and approaches the circle $x^2 + y^2 = 4$ as $\varepsilon \to 0$.

In many cases (polynomial systems for example), the first order Melnikov function has the form

$$M(h, \delta) = \sum_{i=1}^{k} b_i(\delta)\, I_i(h), \quad k \geqslant 2.$$

Let

$$I_1'(\alpha) \neq 0, \qquad I_1(h) \neq 0, \quad \alpha < h < \beta. \tag{3.7}$$

Then we can write

$$M(h, \delta) = I_1(h) \sum_{i=1}^{k} b_i\, J_i(h) = I_1(h) N(h, b), \tag{3.8}$$

where $b = (b_1, \dots, b_n)$, $b_i = b_i(\delta)$, $J_i(h) = I_i(h)/I_1(h)$, $i = 1, 2, \dots, k$.

Introduce the Wronskian of the functions $J_1, J_2, \dots, J_k$

$$W(h) = \begin{vmatrix} J_1(h) & J_2(h) & \dots & J_k(h) \\ J_1'(h) & J_2'(h) & \dots & J_k'(h) \\ \dots & \dots & \dots & \dots \\ J_1^{(k-1)}(h) & J_2^{(k-1)}(h) & \dots & J_k^{(k-1)}(h) \end{vmatrix}. \tag{3.9}$$

Clearly, by a property of determinant we have

$$W'(h) = \begin{vmatrix} J_1(h) & J_2(h) & \dots & J_k(h) \\ J_1'(h) & J_2'(h) & \dots & J_k'(h) \\ \cdots & \cdots & \cdots & \cdots \\ J_1^{(k-2)}(h) & J_2^{(k-2)}(h) & \dots & J_k^{(k-2)}(h) \\ J_1^{(k)}(h) & J_2^{(k)}(h) & \dots & J_k^{(k)}(h) \end{vmatrix}. \tag{3.10}$$

We have

THEOREM 3.2. *Suppose that* (3.7) *and* (3.8) *hold. Let* $|b| > 0$ *for all* $\delta \in D$ *and* $h_0 \in [\alpha, \beta)$.

(i) *If* $W(h_0) \neq 0$, *then Eq.* (3.1) *has cyclicity at most* $k-1$ *at* L_{h_0}.

(ii) *If* $W(h_0) = 0$, $W'(h_0) \neq 0$, *then Eq.* (3.1) *has cyclicity at most* k *at* L_{h_0}.

PROOF. For the first conclusion, let us suppose Eq. (3.1) has cyclicity at least k at L_{h_0}. Then there exist $\varepsilon_n \to \infty$, $\delta_n \in D$ such that for $(\varepsilon, \delta) = (\varepsilon_n, \delta_n)$ Eq. (3.1) has k limit cycles $L_j^{(n)}$ with $L_j^{(n)} \to L_{h_0}$ as $n \to \infty$, $j = 1, 2, \dots, k$. Without loss of generality, we can suppose

$$\delta_n \to \delta_0, \quad b(\delta_n) \to b_0 = (b_{10}, \dots, b_{k0}) \quad \text{as } n \to \infty.$$

Near h_0 we have the following expansion for $N(h, b)$:

$$N(h,b) = \bar{b}_1 + \bar{b}_2(h-h_0) + \dots + \bar{b}_k(h-h_0)^{k-1} + \bar{b}_{k+1}(h-h_0)^k + \cdots, \tag{3.11}$$

where, by (3.8),

$$\bar{b}_{j+1} = \left[\frac{M(h,\delta)}{I_1(h)}\right]^{(j)}_{h=h_0} = \frac{1}{j!}\big[b_1 J_1^{(j)}(h_0) + \dots + b_k J_k^{(j)}(h_0)\big],$$
$$j = 0, 1, \dots, k-1, k. \tag{3.12}$$

It follows that

$$\det \frac{\partial(\bar{b}_1, \dots, \bar{b}_k)}{\partial(b_1, \dots, b_k)} = \frac{W(h_0)}{1!2!\cdots(k-1)!} \neq 0. \tag{3.13}$$

Note that $|b_0| > 0$ by our assumption. By (3.12) and (3.13) we obtain

$$(\bar{b}_1, \dots, \bar{b}_k)\big|_{\delta=\delta_0} = (\bar{b}_{10}, \dots, \bar{b}_{k0}) \neq 0.$$

Thus, an integer l satisfying $1 \leqslant l \leqslant k$ exists such that

$$\bar{b}_{j0} = 0, \quad j = 1, \dots, l-1, \qquad \bar{b}_{l0} \neq 0.$$

Hence, we have by (3.11)

$$N(h, b_0) = \bar{b}_{l0}(h - h_0)^{l-1} + \mathrm{O}\big(|h - h_0|^l\big), \quad \bar{b}_{l0} \neq 0. \tag{3.14}$$

Therefore, by (3.7) and Corollary 2.3 (if $h_0 = \alpha$) or Corollary 3.2 (if $h_0 > \alpha$), there exist $\varepsilon_0 > 0$ and a neighborhood U of L_{h_0} such that for $0 < \varepsilon < \varepsilon_0$, $|\delta - \delta_0| < \varepsilon_0$ Eq. (3.1) has at most $l - 1$ limit cycles in U. This contradicts that Eq. (3.1) has k limit cycles approaching L_{h_0} for $(\varepsilon, \delta) = (\varepsilon_n, \delta_n)$ and $n \to \infty$. This finishes the proof of conclusion (i).

Let $W(h_0) = 0$, $W'(h_0) \neq 0$. If the conclusion (ii) is not true, then, as before, there exists a sequence $(\varepsilon_n, \delta_n)$ approaching $(0, \delta_0)$ such that for $(\varepsilon, \delta) = (\varepsilon_n, \delta_n)$, Eq. (3.1) has $k + 1$ limit cycles approaching L_{h_0} as $n \to \infty$. In this case, formulas (3.11) and (3.12) remain true with

$$\det \frac{\partial(\bar{b}_1, \ldots, \bar{b}_{k-1}, \bar{b}_{k+1})}{\partial(b_1, \ldots, b_k)} = \frac{W'(h_0)}{1!2! \cdots (k-2)!k!} \neq 0, \tag{3.15}$$

and hence

$$\big(\bar{b}_1, \ldots, \bar{b}_{k-1}, \bar{b}_{k+1}\big)\big|_{\delta=\delta_0} = \big(\bar{b}_{10}, \ldots, \bar{b}_{k-1,0}, \bar{b}_{k+1,0}\big) \neq 0.$$

It follows that there exists $1 \leqslant l \leqslant k + 1$ and $l \neq k$ such that (3.14) holds. Thus, a contradiction appears in the same way as above. This ends the proof. ☐

It often happens that $b = 0$ for some $\delta \in D$. In this case, the condition of Theorem 3.2 fails and the following one can apply further.

THEOREM 3.3. *Suppose the following conditions are satisfied.*

(a) *The vector* b *is linear in* δ *with rank* $\frac{\partial b}{\partial \delta} = k$ *and* $b(\delta_0) = 0$ *for some* $\delta_0 \in D$.

(b) *Eq.* (3.1) *is analytic on the closure* $\overline{G}$ *and has a center near* L_α *when* $b = 0$.

(c) *There exists* $h_0 \in [\alpha, \beta)$ *such that* $|W(h_0)| + |W'(h_0)| \neq 0$.

Then

(i) *When* $W(h_0) \neq 0$, *Eq.* (3.1) *has cyclicity* $k - 1$ *at* L_{h_0}.

(ii) *When* $W(h_0) = 0$, $W'(h_0) \neq 0$, *Eq.* (3.1) *has cyclicity* k (*respectively* $k - 1$ *or* k) *at* L_{h_0} *if* $h_0 > \alpha$ (*respectively* $h_0 = \alpha$).

(iii) *For each* $h \in [\alpha, \beta)$, *Eq.* (3.1) *has cyclicity at least* $k - 1$ *at* L_h.

PROOF. Let $W(h_0) \neq 0$ first. By Definition 3.1, it suffices to prove the following two points:

(1) There are at most $k - 1$ limit cycles near L_{h_0} for $\varepsilon > 0$ small and $\delta \in D$.

(2) There can appear $k - 1$ limit cycles in any neighborhood of L_{h_0} for some arbitrarily small $\varepsilon + |\delta - \delta_0|$.

We proceed the proof by contradiction. If the conclusion (1) is not true, then there exists a sequence $(\varepsilon_n, \delta_n) \to (0, \delta^*)$ with $\delta^* \in D$ such that for $(\varepsilon, \delta) = (\varepsilon_n, \delta_n)$ Eq. (3.1) has k

limit cycles which approach L_{h_0} as $n \to \infty$. The proof of Theorem 3.2 implies $b(\delta^*) = 0$. By condition (a) we may assume

$$\det \frac{\partial(b_1, \ldots, b_k)}{\partial(\delta_1, \ldots, \delta_k)} \neq 0.$$

Then for δ near δ^* the linear equation $b = b(\delta)$ has a unique set of solutions $\delta_j = \tilde{\delta}_j(b, \delta_{k+1}, \ldots, \delta_m)$, $j = 1, \ldots, k$. By (3.12) we have

$$\det \frac{\partial(\bar{b}_1, \ldots, \bar{b}_k)}{\partial(\delta_1, \ldots, \delta_k)} = \det \frac{\partial(\bar{b}_1, \ldots, \bar{b}_k)}{\partial(b_1, \ldots, b_k)} \det \frac{\partial(b_1, \ldots, b_k)}{\partial(\delta_1, \ldots, \delta_k)} \neq 0.$$

Further, by condition (b) Eq. (3.1) has a center near L_α when $(\bar{b}_1, \ldots, \bar{b}_k) = 0$. Thus, in the case of $h_0 = \alpha$, by (3.7), (3.8), (3.11) and Theorem 2.7 we know that Eq. (3.1) has Hopf cyclicity $k - 1$ at L_α for $\varepsilon + |\delta - \delta^*|$ small. This contradicts to the existence of k limit cycles near L_α for $(\varepsilon, \delta) = (\varepsilon_n, \delta_n)$. The conclusion (1) above is proved for $h_0 = \alpha$. Since $b(\delta_0) = 0$, using δ_0 instead of δ^*, the above discussion implies that $k - 1$ limit cycles can appear in any neighborhood of L_α for arbitrarily small $\varepsilon + |\delta - \delta_0|$. Then the conclusion (2) follows for $h_0 = \alpha$.

For the case of $h_0 > \alpha$, by (3.3), (3.7), (3.8) and (3.11) we have

$$\begin{aligned} F(h, \varepsilon, \delta) &= I_1(h)\left[\sum_{j=1}^{k} b_j J_j(h) + \mathrm{O}(\varepsilon)\right] \\ &= I_1(h)\left[\sum_{j=1}^{k} \tilde{b}_j (h - h_0)^{j-1} + \mathrm{O}\big(|h - h_0|^k\big)\right], \end{aligned} \tag{3.16}$$

where $\tilde{b}_j = \bar{b}_j + \mathrm{O}(\varepsilon)$, $j = 1, \ldots, k$.

Also, by (3.13) and condition (b) Eq. (3.1) has a center near L_α for $(\bar{b}_1, \ldots, \bar{b}_k) = 0$ and hence for h near h_0,

$$F(h, \varepsilon, \delta) = 0 \quad \text{if } \big(\bar{b}_1, \ldots, \bar{b}_k\big) = 0.$$

Thus (3.16) can be rewritten as

$$F(h, \varepsilon, \delta) = I_1(h) \sum_{j=1}^{k} \tilde{b}_j (h - h_0)^{j-1}\big[1 + P_j(h, \varepsilon, \delta)\big], \tag{3.17}$$

where $\tilde{b}_j = \bar{b}_j + \mathrm{O}(\varepsilon|\bar{b}_1, \ldots, \bar{b}_k|)$, $P_j(h, \varepsilon, \delta) = \mathrm{O}(|h - h_0|^{k-j+1})$, $j = 1, \ldots, k$. Then using the form of (3.17) and similar to the proof of Theorem 2.7 we can prove that F has at most $k - 1$ zeros near $h = h_0$ for $\varepsilon + |\delta - \delta^*|$ small. A contradiction occurs too as before. Also, as before, by using (3.17) F must have $k - 1$ zeros in h near $h = h_0$ for $(\tilde{b}_1, \ldots, \tilde{b}_k)$

satisfying $0 < |\tilde{b}_j| \ll |\tilde{b}_{j+1}| \ll |\tilde{b}_k|$, $\tilde{b}_j \tilde{b}_{j+1} < 0$, $j = 1, \dots, k-1$. Hence, the proof of the first conclusion of the theorem is completed.

To prove the second one, suppose $W(h_0) = 0$, $W'(h_0) \neq 0$ with $h_0 > \alpha$. Then by (3.9) and (3.10) there exist constants $\alpha_0, \dots, \alpha_{k-2}$ such that

$$\left(J_1^{(k-1)}(h_0), \dots, J_k^{(k-1)}(h_0)\right) = \sum_{j=0}^{k-2} \alpha_j \left(J_1^{(j)}(h_0), \dots, J_k^{(j)}(h_0)\right).$$

Hence, by (3.12) we have

$$\bar{b}_k = \sum_{j=1}^{k-1} \bar{\alpha}_j \bar{b}_j, \tag{3.18}$$

for some constants $\bar{\alpha}_1, \dots, \bar{\alpha}_{k-1}$. Therefore, by (3.15), (3.18), similar to (3.17) we obtain

$$\begin{aligned} F(h, \varepsilon, \delta) = I_1(h) \Bigg[&\sum_{j=1, j\neq k}^{k+1} \tilde{b}_j (h-h_0)^{j-1} \left(1 + \mathrm{O}\left(|h-h_0|^{k-j+2}\right)\right) \\ &+ \left(\sum_{j=1}^{k-1} \bar{\alpha}_j \bar{b}_j + \mathrm{O}\left(\varepsilon \left|\bar{b}_1, \dots, \bar{b}_{k-1}, \bar{b}_{k+1}\right|\right) \right) \cdot (h-h_0)^{k-1} \Bigg], \end{aligned}$$

where

$$\tilde{b}_j = \bar{b}_j + \mathrm{O}\left(\varepsilon \left|\bar{b}_1, \dots, \bar{b}_{k-1}, \bar{b}_{k+1}\right|\right), \quad j = 1, \dots, k-1, k+1.$$

Note that

$$\bar{b}_j = \tilde{b}_j + \mathrm{O}\left(\varepsilon \left|\tilde{b}_1, \dots, \tilde{b}_{k-1}, \tilde{b}_{k+1}\right|\right), \quad j = 1, \dots, k-1, k+1.$$

We have further

$$F = I_1(h) \sum_{j=1}^{k+1} \tilde{b}_j (h-h_0)^{j-1} \left(1 + \widetilde{P}_j\right), \tag{3.19}$$

where

$$\begin{aligned} &\widetilde{P}_j = \left(\bar{\alpha}_j + \mathrm{O}(\varepsilon)\right)(h-h_0)^{k-j}, \quad j = 1, \dots, k-1, \\ &\widetilde{P}_k = 0, \qquad \widetilde{P}_{k+1} = \mathrm{O}\left(|h-h_0|\right), \qquad \tilde{b}_k = \mathrm{O}\left(\varepsilon \tilde{b}_{k+1}\right). \end{aligned}$$

Using (3.19), similar to Theorem 2.7, one can prove that Eq. (3.1) has at most k limit cycles near L_{h_0} for ε small and $\delta \in D$.

Furthermore, we can prove that k limit cycles can appear in any neighborhood of L_{h_0}. In fact, let us take

$$h - h_0 = \lambda\varepsilon, \qquad \tilde{b}_j = B_j, \varepsilon^{k+1-j}, \quad j = 1, \ldots, k-1, k+1,$$

where B_j are such constants that the polynomial in λ

$$g(\lambda) = B_1 + B_2\lambda + \cdots + B_{k-1}\lambda^{k-2} + B_{k+1}\lambda^k$$

has k simple zeros $\lambda_j \neq 0$, $j = 1, \ldots, k$. Then (3.19) becomes

$$F = \varepsilon^k I_1(h)\bigl[g(\lambda) + \mathrm{O}(\varepsilon)\bigr],$$

which has k simple zeros $\tilde{\lambda}_j = \lambda_j + \mathrm{O}(\varepsilon)$ in λ, $j = 1, \ldots, k$. Thus F has k simple zeros $h_j = h_0 + \tilde{\lambda}_j\varepsilon$ in h, $j = 1, \ldots, k$.

For $h_0 = \alpha$, we may assume $\alpha = 0$. Then noting (3.18), similar to (2.64) we have

$$\begin{aligned} F = {} & \bar{b}_1\bigl(1 + \mathrm{O}\bigl(|\varepsilon, r|\bigr)\bigr) + \bar{b}_2 r^2\bigl(1 + \mathrm{O}\bigl(|\varepsilon, r|\bigr)\bigr) + \cdots + \bar{b}_{k-1} r^{2(k-2)} \\ & \times \bigl(1 + \mathrm{O}\bigl(|\varepsilon, r|\bigr)\bigr) + \bar{b}_{k+1} r^{2(k-1)}\mathrm{O}(\varepsilon) + \bar{b}_{k+1} r^{2k}\bigl(1 + \mathrm{O}\bigl(|\varepsilon, r|\bigr)\bigr). \end{aligned}$$

It is easy to see that F has at most k zeros in $r > 0$ and $k - 1$ zeros can appear.

For conclusion (iii), let $h \in [\alpha, \beta)$ and U be any neighborhood of L_h. Since W is analytic on $[\alpha, \beta)$ there exists $\bar{h} > h$ such that $W(\bar{h}) \neq 0$ and $L_{\bar{h}} \subset U$. By the conclusion (i) Eq. (3.1) has $k - 1$ limit cycles in U for some (ε, δ). Since U is arbitrary it follows that L_h has cyclicity at least $k - 1$. The proof is completed. ☐

By (3.17) and (3.19) one can prove easily

COROLLARY 3.3. *Suppose the conditions* (a)–(c) *hold with* $h_0 > \alpha$. *If*

(i) $W(h_0) \neq 0$, $1 \leqslant l \leqslant k-1$, *or*

(ii) $W(h_0) = 0$, $W'(h_0) \neq 0$, $1 \leqslant l \leqslant k$, $l \neq k-1$,

then there exists a function $\delta = \delta(\varepsilon)$ *with* $\delta(0) \in D$ *such that for* $\delta = \delta(\varepsilon)$ *and* $\varepsilon > 0$ *small Eq.* (3.1) *has a limit cycle of multiplicity* l *which approaches* L_{h_0} *as* $\varepsilon \to 0$.

REMARK 3.1. Under conditions of Theorem 3.3, the function W is analytic and has only isolated zeros on $[\alpha, \beta)$. Thus for any $\bar{h} \in (\alpha, \beta)$, there exist $\alpha \leqslant h_1 < h_2 < \cdots < h_l < \bar{h}$, $l \geqslant 0$ such that Eq. (3.1) has cyclicity $k - 1$ at L_h for $h \in [\alpha, \bar{h}) - \{h_1, \ldots, h_l\}$.

EXAMPLE 3.2. Consider the Liénard system (2.66) discussed in Example 2.7

$$\dot{x} = y - \varepsilon \sum_{i=1}^{2n+1} a_i x^i, \qquad \dot{y} = -x.$$

As before, suppose that $\varepsilon > 0$ is small and $|a_i| \leqslant 1$ for $i = 1, \ldots, 2n+1$ with $n \geqslant 1$.

We claim that for each $h \geqslant 0$ the above system has cyclicity n at the circle $x^2 + y^2 = 2h$.

In fact, by the discussion in Example 2.7 we have

$$M(h)=\sum_{j=0}^{n} b_{j+1}h^{j+1}, \quad b_{j+1}=-2^{j+1}N_j a_{2j+1},\ N_j>0,\ j=0,\dots,n.$$

Comparing with (3.8) we may take

$$I_1(h)=h, \qquad J_j(h)=h^{j-1}, \quad j=1,\dots,n+1.$$

Hence, by (3.9) we have $W(h)=1$ for all $h\geqslant 0$. Thus the claim follows from Theorem 3.3 and Theorem 2.3(i).

EXAMPLE 3.3. For the system

$$\dot{x}=y-\varepsilon\sum_{i=0}^{n} a_{2i+1}x^{2i+1}, \qquad \dot{y}=-x(1-x),$$

we have

$$M(h)=\sum_{j=0}^{n} b_{j+1}h^{j+1}\bigl(1+\mathrm{O}(h)\bigr)$$

for $0<h\ll 1$. It follows $W(0)=1$. Thus, by Remark 3.1 there may exist finitely many values $0<h_1<\cdots<h_l$ in the interval $(0,\frac{1}{6})$ such that for any $h\in[0,\frac{1}{6})-\{h_1,\dots,h_l\}$ (respectively $h\in\{h_1,\dots,h_l\}$) the above system has cyclicity n (respectively at least n) at L_h.

DEFINITION 3.2. Let $U\in\mathbb{R}^2$ be a bounded set and N_0 a positive integer. We call N_0 *the cyclicity of* U for Eq. (3.1) with $\delta\in D$ and $\varepsilon>0$ small if the following are satisfied:

(i) For any given compact set $V\in U$ Eq. (3.1) has at most N_0 limit cycles in V for all $\delta\in D$ and $0<\varepsilon<\varepsilon_0$, where $\varepsilon_0=\varepsilon_0(V)>0$.

(ii) Eq. (3.1) has N_0 limit cycles for some (ε,δ) with $\delta\in D$ whose limits as $\varepsilon\to 0$ are in U.

The cyclicity of the set $G=\bigcup_{h\in(\alpha,\beta)}L_h$ for Eq. (3.1) is also called the cyclicity of the period annulus $\{L_h\colon \alpha<h<\beta\}$.

The following theorem gives a sufficient condition for finding the cyclicity of the open sets G and $G\cup L_\alpha$.

THEOREM 3.4. *Suppose* (3.7) *and* (3.8) *hold. Let the conditions* (a) *and* (b) *of Theorem* 3.3 *are satisfied. Let further, for each* $b\neq 0$ *the function* $N(h,b)$ *has at most* N_0 *zeros* (*taking multiplicity into account*) *in* $h\in[\alpha,\beta)$ (*respectively* $h\in(\alpha,\beta)$) *and for some* $b\neq 0$ *it has* N_0 *simple zeros in* $h\in(\alpha,\beta)$. *Then the cyclicity of the set* $G\cup L_\alpha$ (*respectively* G) *for Eq.* (3.1) *is* N_0 *as* G *is bounded.*

PROOF. For the sake of simplicity, we suppose that the singular point of Eq. (3.1) near L_α is at the origin with $\alpha = 0$. Then we can take a cross section l which is on the positive x-axis with an endpoint at the origin. In this case we have

$$A(h) = L_h \cap l = \bigl(a(h), 0\bigr), \quad B(h, \varepsilon, \delta) = \bigl(b^*(h, \varepsilon, \delta), 0\bigr)$$

for $h > 0$ small. By (2.4), the function b^* is analytic in a. Thus, $b^* = \mathrm{O}(a)$ and $H(B) - H(A) = \mathrm{O}(a^2) = \mathrm{O}(h)$. Then it follows from (3.3) that $F(h, \varepsilon, \delta) = \mathrm{O}(h)$. As before, suppose

$$\det \frac{\partial(b_1, \ldots, b_k)}{\partial(\delta_1, \ldots, \delta_k)} \neq 0.$$

Then we can solve $\delta_i = \tilde{\delta}_i(b, \delta_{k+1}, \ldots, \delta_m)$, $i = 1, \ldots, k$ from $b = b(\delta)$. Hence, for $h \in [0, \beta)$ we have

$$F(h, \varepsilon, \delta) = I_1(h)\bigl[N(h, b) + \mathrm{O}(\varepsilon)\bigr] \equiv F^*(h, \varepsilon, b, \delta_{k+1}, \ldots, \delta_m). \tag{3.20}$$

By our assumption and Corollary 3.1 Eq. (3.1) can have N_0 limit cycles for some (ε, δ). What we need to do is to prove that for any given constants $0 < \lambda < \beta$ (respectively $0 < \mu < \lambda < \beta$) there exists $\varepsilon_0 > 0$ such that for $0 < \varepsilon < \varepsilon_0$, $\delta \in D$ the function F has at most N_0 zeros in $h \in (0, \lambda]$ (respectively $[\mu, \lambda]$). If the conclusion is not true, then there exists a sequence $\{(\varepsilon_j, \delta_j)\}$ with $\varepsilon_j \to 0, \delta_j \to \delta_0 \in D$ as $j \to \infty$ such that $F(h, \varepsilon_j, \delta_j)$ has $N_0 + 1$ zeros h_{ij}, $i = 1, \ldots, N_0 + 1$ in $h \in (0, \lambda]$ (respectively $[\mu, \lambda]$). We can suppose $h_{ij} \to h_{i0} \in [0, \lambda]$ (respectively $[\mu, \lambda]$) as $j \to \infty$. Then by (3.20)

$$N(h_{i0}, b_0) = 0, \quad i = 1, \ldots, N_0 + 1,$$

where $b_0 = b(\delta_0)$. Hence, by Corollaries 2.3 and 3.2 the function $N(h, b_0)$ has at least $N_0 + 1$ zeros (multiplicity taken into account) in $[0, \lambda]$ (respectively $[\mu, \lambda]$). This implies $b_0 = 0$.

On the other hand, we have $F^*|_{b=0} = 0$ on $[0, \lambda]$. This yields

$$\begin{aligned} F^* &= \sum_{i=1}^{k} b_i F_i(h, \varepsilon, b, \delta_{k+1}, \ldots, \delta_m) \\ &= I_1(h)\bigl[N(h, b) + \mathrm{O}\bigl(\varepsilon|b|\bigr)\bigr] \\ &= |b| I_1(h)\bigl[N(h, c) + \mathrm{O}(\varepsilon)\bigr] \\ &\equiv |b| I_1(h) G(h, \varepsilon, c, \delta_{k+1}, \ldots, \delta_m), \end{aligned} \tag{3.21}$$

where $c = \frac{b}{|b|} = (c_1, \ldots, c_k)$. Let

$$c^{(j)} = \frac{b(\delta_j)}{|b(\delta_j)|}, \quad j \geqslant 1.$$

Then $b(\delta_j) \to b(\delta_0) = 0$, $j \to \infty$. We can assume $c^{(j)} \to c_0$ with $|c_0| = 1$. Note that

$$F(h_{ij}, \varepsilon_j, \delta_j) = 0, \quad j \geqslant 1,\ i = 1, \dots, N_0 + 1.$$

It follows from (3.20) and (3.21) that $N(h_{i0}, c_0) = 0$, $i = 1, \dots, N_0 + 1$, which contradicts to our assumption. The proof is completed. ☐

REMARK 3.2. Let the conditions of Theorem 3.4 be satisfied. If G is unbounded, then there exists a compact set $V_0 \subset G \cup L_\alpha$ (respectively $\subset G$) such that for any compact set V satisfying $V_0 \subset V \subset G \cup L_\alpha$ (respectively $V_0 \subset V \subset G$) Eq. (3.1) has cyclicity N_0 on V.

EXAMPLE 3.4. Consider Eq. (2.66) again. Since

$$N(h, b) = \sum_{j=0}^{n} b_{j+1} h^j,$$

in this case, by the discussion in Example 3.2 for any compact set V containing the origin its cyclicity is n.

An open problem for Eq. (3.1) is: What is the maximal number of limit cycles on the plane? The above example suggests that the answer be n. The most difficult part is to study the number of limit cycles which disappear into infinity as $\varepsilon \to 0$.

3.2. *Existence of 2 and 3 limit cycles*

By (3.8), the function N can be written in the form

$$N(h, b) = b_1 - P(h, b_2, \dots, b_k). \tag{3.22}$$

The function P here is called a detection function and its graph on the (h, b_1) plane a detection curve. For a given system, an interesting problem is to find a point $(b_{10}, b_{20}, \dots, b_{k0})$ such that the line $b_1 = b_{10}$ and the curve $b_1 = P(h, b_{20}, \dots, b_{k0})$ have as many intersection points as possible.

The simplest case is that P is monotonic in $h \in (\alpha, \beta)$. Some sufficient conditions for some special systems on the monotonicity of P were obtained by Li and Zhang [84], and Han [49]. Obviously, if $P(\alpha, b_2, \dots, b_k) \neq P(\beta, b_2, \dots, b_k)$ for some $(b_2, \dots, b_k)$ then Eq. (3.1) can have a limit cycle.

Next, we give some conditions for Eq. (3.1) to have 2 or 3 limit cycles. We will suppose $\beta < \infty$ and L_β is a homoclinic loop with a hyperbolic saddle S on it. First, we prove

LEMMA 3.3. *Let $\phi(x, y)$ be a C^∞ function with $\phi(S) = 0$. Then along the orbit L_h of Eq.* (3.2) *the limit* $\lim_{h\to\beta} \oint_{L_h} \phi(x, y)\, \mathrm{d}t = \oint_{L_\beta} \phi(x, y)\, \mathrm{d}t$ *exists finitely.*

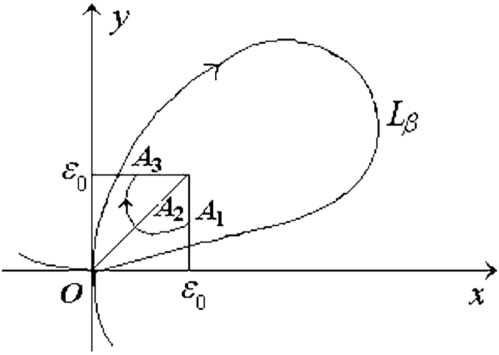

Fig. 10.

PROOF. Without loss of generality, we may suppose the saddle S is at the origin and the Eq. (3.2) has the form

$$\dot{x} = \lambda x + f(x, y), \quad \dot{y} = -\lambda y + g(x, y) \tag{3.23}$$

where $f,\ g = \mathrm{O}(|x, y|^2)$, which implies that $H(x, y) = \lambda xy + \mathrm{O}(|x, y|^3)$, $\lambda \neq 0$ with $\beta = 0$. For definiteness, assume $\lambda < 0$ and L_h locates in the first quadrant. See Fig. 10.

For $\varepsilon_0 > 0$ small take points $A_1 \in L_h \cap \{x = \varepsilon_0\}$, $A_2 \in L_h \cap \{x = y\}$, $A_3 \in L_h \cap \{y = \varepsilon_0\}$. Then the coordinate (a, a) of A_2 satisfies $a = a(h) = \sqrt{\frac{h}{\lambda}} + \mathrm{O}(h)$. Let $y = xu$. Then

$$H(x, y) = x^2\big[\lambda u + x\phi_0(x, u)\big],$$

where, by the integral mean value theorem, $\phi_0 \in C^\infty$. The orbit arc $\widehat{A_1 A_2}$ satisfies the equation

$$H(x, y) = h, \quad a(h) \leqslant x \leqslant \varepsilon_0,$$

which is equivalent to

$$V(x, u, v) = 0, \quad a(h) \leqslant x \leqslant \varepsilon_0, \tag{3.24}$$

where $V(x, u, v) = \lambda u + x\phi_0(x, u) - v$, $v = \frac{h}{x^2} \in [\frac{h}{\varepsilon_0^2}, \frac{h}{a^2}]$. Note that

$$V\left(0, \frac{v}{\lambda}, v\right) = 0, \qquad V_u\left(0, \frac{v}{\lambda}, v\right) = \lambda.$$

Taking v as a parameter we can solve uniquely from (3.24)

$$u = u(x, v) = \frac{v}{\lambda} + \mathrm{O}(x) \quad \text{with } u_v = \frac{1}{\lambda} + \mathrm{O}(x).$$

It is clear that along $\widehat{A_1A_2}$

$$\frac{\phi(x,y)}{\lambda x+f(x,y)}=\frac{\phi(x,xu(x,v))}{\lambda x+f(x,xu(x,v))}=\frac{\phi(S)}{\lambda x}+R_0(x)+R_1(x,v)v, \tag{3.25}$$

where $R_0, R_1 \in C^\infty$. Hence, by (3.23) and $\phi(S)=0$

$$\int_{\widehat{A_1A_2}}\phi(x,y)\,\mathrm{d}t=\int_{\varepsilon_0}^{a}(R_0+R_1v)\,\mathrm{d}x=\int_{\varepsilon_0}^{a}R_0\,\mathrm{d}x+\int_{\varepsilon_0}^{a}R_1v\,\mathrm{d}x.$$

Since

$$\left|\int_{\varepsilon_0}^{a}v\,\mathrm{d}x\right|=\left|h\int_{\varepsilon_0}^{a}\frac{\mathrm{d}x}{x^2}\right|=\left|\frac{h}{a}-\frac{h}{\varepsilon_0}\right|=\mathrm{O}\big(|h|^{1/2}\big),$$

it follows that

$$\lim_{h\to 0}\int_{\widehat{A_1A_2}}\phi(x,y)\,\mathrm{d}t=\int_{\varepsilon_0}^{0}R_0\,\mathrm{d}x=\int_{\widehat{A_{10}A_{20}}}\phi(x,y)\,\mathrm{d}t\in\mathbb{R},$$

where $A_{i0}=\lim_{h\to 0}A_i$, $i=1,2,3$.

Similarly,

$$\lim_{h\to 0}\int_{\widehat{A_2A_3}}\phi(x,y)\,\mathrm{d}t=\int_{\widehat{A_{20}A_{30}}}\phi(x,y)\,\mathrm{d}t\in\mathbb{R}.$$

Also, it is obvious that

$$\lim_{h\to 0}\int_{\widehat{A_3A_1}}\phi(x,y)\,\mathrm{d}t=\int_{\widehat{A_{30}A_{10}}}\phi(x,y)\,\mathrm{d}t\in\mathbb{R}.$$

Thus

$$\begin{aligned}\lim_{h\to 0}\oint_{L_h}\phi(x,y)\,\mathrm{d}t&=\lim_{h\to 0}\int_{\widehat{A_1A_2}\cup\widehat{A_2A_3}\cup\widehat{A_3A_1}}\phi(x,y)\,\mathrm{d}t\\&=\int_{\widehat{A_{10}A_{20}}}\phi\,\mathrm{d}t+\int_{\widehat{A_{20}A_{30}}}\phi\,\mathrm{d}t+\int_{\widehat{A_{30}A_{10}}}\phi\,\mathrm{d}t\\&=\oint_{L_\beta}\phi(x,y)\,\mathrm{d}t\in\mathbb{R}.\end{aligned}$$

This finishes the proof. □

By Lemmas 3.2 and 3.3 we have immediately

COROLLARY 3.4. *Let L_h be oriented clockwise and expand with h increasing. Then for any C^∞ functions $\bar{p}(x,y)$ and $\bar{q}(x,y)$ the Abelian*

$$I(h)=\oint_{L_h}\bar{q}\,\mathrm{d}x-\bar{p}\,\mathrm{d}y$$

has the derivative

$$I'(h)=\oint_{L_h}(\bar{p}_x+\bar{q}_y)\,\mathrm{d}t,$$

and

$$I'(\alpha)=(\bar{p}_x+\bar{q}_y)(L_\alpha)T_\alpha,\qquad I'(h)=c_0T_h+c_1+c_2(h),$$

where T_h denotes the period of L_h, $T_\alpha=\lim_{h\to\alpha}T_h$, $c_0=(\bar{p}_x+\bar{q}_y)(S)$, $c_1=\oint_{L_\beta}[\bar{p}_x+\bar{q}_y-c_0]\,\mathrm{d}t$, $\lim_{h\to\beta}c_2(h)=0$. Further, by (3.25) *it is easy to see that*

$$\lim_{h\to\beta}\frac{T_h}{\ln|h-\beta|}=p_0<0.\tag{3.26}$$

The following lemma gives formulas for computing the value of the function P and its derivative at $h=\alpha$.

LEMMA 3.4. *Let* (3.7), (3.8) *and* (3.22) *hold. Suppose*

$$(p_x+q_y)(L_\alpha,0,\delta)=\sum_{j=1}^{k}d_{j0}b_j,\quad d_{10}\neq 0,\tag{3.27}$$

and

$$v_3^*=\sum_{j=2}^{k}v_{3j}b_j\quad \text{as } b_1=-\frac{1}{d_{10}}\sum_{j=2}^{k}d_{j0}b_j,\tag{3.28}$$

where $v_3^*=\frac{\partial v_3}{\partial\varepsilon}|_{\varepsilon=0}$ and v_3 is the first focus value of Eq. (3.1) *at the focus near L_α obtained by using Theorem* 2.1, *and d_{j0} $(1\leqslant j\leqslant k)$ and $v_{3j}(2\leqslant j\leqslant k)$ are constants. Then*

$$P(\alpha,b_2,\dots,b_k)=-\frac{1}{d_{10}}\sum_{j=2}^{k}d_{j0}b_j,$$

$$P_h'(\alpha,b_2,\dots,b_k)=-\frac{4\pi}{Kb_{10}}\sum_{j=2}^{k}v_{3j}b_j,$$

where $K>0$, and $b_{10}=I_1'(\alpha)$ which can be obtained by Corollary 3.4.

PROOF. Let

$$I_j(h) = b_{j0}(h-\alpha) + b_{j1}(h-\alpha)^2 + \mathrm{O}\big(|h-\alpha|^3\big), \quad j = 1, \ldots, k.$$

Then

$$M(h,\delta) = b_0^*(h-\alpha) + b_1^*(h-\alpha)^2 + \mathrm{O}\big(|h-\alpha|^3\big),$$

where $b_i^* = \sum_{j=1}^k b_{ji} b_j$, $i = 0, 1$. By Lemma 2.9 and Corollary 3.4 we have

$$b_0^* = 0 \quad \text{if and only if} \quad (p_x + q_y)(L_\alpha, 0, \delta) = 0,$$

and

$$v_3^* = \frac{K}{4\pi} b_1^* \quad \text{when } b_0^* = 0.$$

Therefore, by (3.27) $b_0^* = 0$ implies

$$b_1 = -\frac{1}{b_{10}} \sum_{j=2}^k b_{j0} b_j = -\frac{1}{d_{10}} \sum_{j=2}^k d_{j0} b_j,$$

and hence

$$v_3^* = \frac{K}{4\pi}\left[b_{11} b_1 + \sum_{j=2}^k b_{j1} b_j \right] = \frac{K}{4\pi b_{10}} \sum_{j=2}^k (b_{10} b_{j1} - b_{11} b_{j0}) b_j,$$

when $b_0^* = 0$. Hence, by (3.22) and (3.8)

$$\begin{aligned}
P(h, b_2, \ldots, b_k) &= -\sum_{j=2}^k \frac{b_j I_j(h)}{I_1(h)} \\
&= -\sum_{j=2}^k \frac{b_j[b_{j0} + b_{j1}(h-\alpha) + \mathrm{O}(|h-\alpha|^2)]}{b_{10} + b_{11}(h-\alpha) + \mathrm{O}(|h-\alpha|^2)} \\
&= -\frac{1}{b_{10}^2} \sum_{j=2}^k b_j \big[b_{10} b_{j0} + (b_{10} b_{j1} - b_{11} b_{j0})(h-\alpha) \\
&\quad + \mathrm{O}\big(|h-\alpha|^2\big) \big] \\
&= -\frac{1}{b_{10}} \sum_{j=2}^k b_{j0} b_j - \frac{4\pi}{K b_{10}} v_3^*(h-\alpha) + \mathrm{O}\big(|h-\alpha|^2\big)
\end{aligned}$$

$$= -\frac{1}{d_{10}}\sum_{j=2}^{k} d_{j0}b_j - \frac{4\pi}{Kb_{10}}\sum_{j=2}^{k} v_{3j}b_j(h-\alpha) + \mathrm{O}\big(|h-\alpha|^2\big).$$

Then the conclusion follows from (3.28) and the above easily. The proof is ended. □

Now we can give a condition for the existence of 2 limit cycles.

THEOREM 3.5. *Let L_h be oriented clockwise and expand with h increasing. Suppose* (3.7), (3.8), (3.22), (3,27) *and* (3.28) *are satisfied. If there exists $\delta_0 \in D$ such that*

$$\text{(i)}\quad (p_x + q_y)(S, 0, \delta_0) = \sum_{j=1}^{k} d_j b_j(\delta_0),$$

$$\sigma(\delta_0) = \sum_{j=2}^{k}\left(d_j - \frac{\mathrm{d}_1 I_j(\beta)}{I_1(\beta)}\right)b_j(\delta_0) \neq 0;$$

$$\text{(ii)}\quad \sigma(\delta_0)\sum_{j=2}^{k} v_{3j}b_j(\delta_0) < 0;$$

$$\text{(iii)}\quad b_1'(\delta_0) \neq 0 \quad \textit{and}$$

$$b_1(\delta_0) = \begin{cases} \min\big\{P\big(\alpha, b_2(\delta_0), \dots, b_k(\delta_0)\big), P\big(\beta, b_2(\delta_0), \dots, b_k(\delta_0)\big)\big\} \\ \quad \textit{as } \sigma(\delta_0)I_1(\beta) < 0, \\ \max\big\{P\big(\alpha, b_2(\delta_0), \dots, b_k(\delta_0)\big), P\big(\beta, b_2(\delta_0), \dots, b_k(\delta_0)\big)\big\} \\ \quad \textit{as } \sigma(\delta_0)I_1(\beta) > 0 \end{cases}$$

then Eq. (3.1) *has at least two limit cycles for some* (ε, δ) *near* $(0, \delta_0)$.

PROOF. By (3.8) and (3.22) we have $M = I_1(b_1 - P)$. Hence $M' = I_1'(b_1 - P) - I_1 P'$ and

$$\frac{P'}{T_h} = \frac{I_1'}{T_h}\cdot\frac{b_1 - P}{I_1} - \frac{M'}{T_h}\cdot\frac{1}{I_1}.$$

Take $b_1 = P(\beta, b_2, \dots, b_k)$ and apply Corollary 3.4 to function I_1 and M so that

$$\begin{aligned}\lim_{h\to\beta}\frac{P'}{T_h} &= -\frac{1}{I_1(\beta)}\lim_{h\to\beta}\frac{M'}{T_h}\bigg|_{b_1 = P(\beta, b_2, \dots, b_k)} \\ &= -\frac{1}{I_1(\beta)}(p_x + q_y)(S, 0, \delta)|_{b_1 = P(\beta, b_2, \dots, b_k)} \\ &= -\frac{1}{I_1(\beta)}\sigma(\delta).\end{aligned} \tag{3.29}$$

Then noting $I_1'(\alpha)I_1(\beta) > 0$, by Lemma 3.4 we know that for h near β the product $P_h'(\alpha, b_2, \ldots, b_k)P_h'(h, b_2, \ldots, b_k)$ has the same sign as $\sigma(\delta)\sum_{j=2}^{k} v_{3j}b_j$. Then it follows from (ii) that for $\delta = \delta_0$ the function $P(h, b_2, \ldots, b_k)$ has a minimum or maximum in the interval (α, β). Therefore, by (3.29) and (iii) for some δ near δ_0 the function $b_1 - P(h, b_2, \ldots, b_k)$ has two zeros with odd multiplicity in the interval (α, β). Then the conclusion follows from Theorem 3.1. This ends the proof. □

EXAMPLE 3.5. Consider the system

$$\dot{x} = y(1 - y) - \varepsilon\bigl(x^3 - \delta x\bigr), \qquad \dot{y} = -x, \tag{3.30}$$

where $\varepsilon > 0$ is small and $\delta \in \mathbb{R}$ is bounded. For $\varepsilon = 0$, Eq. (3.30) has a family of periodic orbits giving by

$$L_h\colon\ \frac{1}{2}\bigl(x^2 + y^2\bigr) - \frac{1}{3}y^3 = h, \quad 0 < h < \frac{1}{6},\ y < 1.$$

By (3.4) we have

$$M(h, \delta) = \delta I_1(h) - 3I_2(h) = I_1(h)\bigl(\delta - P(h)\bigr)$$

where

$$P(h) = \frac{3I_2(h)}{I_1(h)},$$
$$I_j(h) = -\frac{1}{2j - 1}\oint_{L_h} x^{2j-1}\,\mathrm{d}y = \iint_{Int.L_h} x^{2j-2}\,\mathrm{d}x\,\mathrm{d}y, \quad j = 1, 2.$$

By Corollary 3.4, $I_1(h) = 2\pi h + \mathrm{O}(h^2)$, $I_2(h) = \mathrm{O}(h^2)$. By Theorem 2.1, we have $v_3^* = -\frac{3}{8}$ as $\delta = 0$. Let

$$\sigma = \frac{3I_2(\frac{1}{6})}{I_1(\frac{1}{6})} = \delta_0.$$

Since $L_{1/6}$ can be represented as $x^2 = \frac{2}{3}(y - 1)^2(y + \frac{1}{2})$, $-\frac{1}{2} \leqslant y \leqslant 1$, it is easy to see that

$$I_1\left(\frac{1}{6}\right) = 2\int_{-1/2}^{1}(1 - y)\sqrt{1 - \frac{2}{3}(1 - y)}\,\mathrm{d}y = \frac{6}{5},$$
$$I_2\left(\frac{1}{6}\right) = \frac{2}{3}\int_{-1/2}^{1}(1 - y)^3\left(1 - \frac{2}{3}(1 - y)\right)^{3/2}\mathrm{d}y = \frac{108}{385}.$$

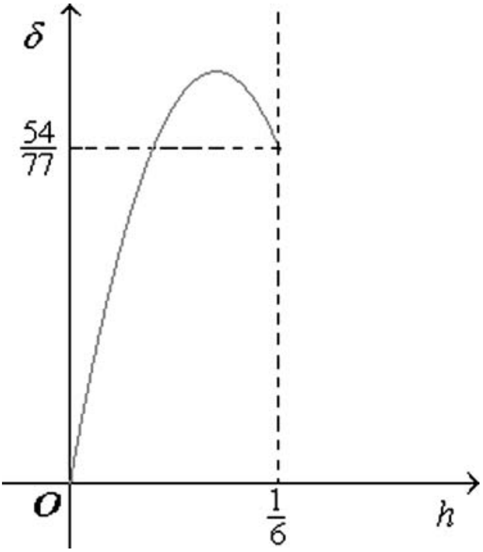

Fig. 11. The graph of $P(h)$ for Eq. (3.27).

Thus, $\delta_0 = \frac{54}{77}$. By Theorem 3.5 for Eq. (3.30) the system has two limit cycles for (ε, δ) near $(0, \frac{54}{77})$ with $\delta > \frac{54}{77}$. The graph of the function $\delta = P(h)$ on the (h, δ) plan is as shown in Fig. 11.

For the existence of three limit cycles, we have:

THEOREM 3.6. *Let L_h be oriented clockwise and expand with h increasing. Suppose* (3.7), (3.8), (3.22), (3.27) *and* (3.28) *are satisfied. Assume further*

(i) *there exists $\delta_0 \in D$ such that*

$$(p_x + q_y)(S, 0, \delta_0) \sum_{j=2}^{k} v_{3j} b_j(\delta_0) > 0, \quad b_1'(\delta_0) \neq 0,$$

$$b_1(\delta_0) = P\big(\alpha, b_2(\delta_0), \dots, b_k(\delta_0)\big) = P\big(\beta, b_2(\delta_0), \dots, b_k(\delta_0)\big);$$

(ii) *there exists δ^* near δ_0 such that*

$$\begin{aligned} &I_1(\beta)(p_x + q_y)(S, 0, \delta_0) \\ &\quad \times \big[P\big(\alpha, b_1(\delta^*), \dots, b_k(\delta^*)\big) - P\big(\beta, b_1(\delta^*), \dots, b_k(\delta^*)\big)\big] > 0. \end{aligned}$$

Then for $\varepsilon > 0$ small and $\delta = \delta^*$ Eq. (3.1) *has* 3 *limits cycles.*

We will give an example to show the way to prove the above theorem.

EXAMPLE 3.6. Consider a system of the form

$$\begin{cases} \dot{x} = y(1-y) - \varepsilon\big(x^3 - \delta_1 x + \delta_2 xy\big), \\ \dot{y} = -x. \end{cases} \tag{3.31}$$

We claim that for $\varepsilon > 0$, $\delta_1 < 0$, $\delta_2 < -54/11$ and $\varepsilon + |\delta_1| + |\delta_2 + 54/11|$ small Eq. (3.31) has 3 limit cycles.

For this system we have

$$M(h) = b_1 I_1(h) + b_2 I_2(h) + b_3 I_3(h),$$

where $b_1 = \delta_1$, $b_2 = -3$, $b_3 = \delta_2$ and $I_1(h)$, $I_2(h)$ are the same as in Example 3.5, and $I_3(h) = \oint_{L_h} xy\,\mathrm{d}y$ with $I_3(\frac{1}{6}) = -\frac{6}{35}$. Let

$$P(h, b_2, b_3) = -\frac{1}{I_1(h)}\big[b_2 I_2(h) + b_3 I_3(h)\big].$$

Also, let $b_{10} = \delta_{10} = 0$, $b_{20} = -3$, $b_{30} = \delta_{20} = 3I_2(\frac{1}{6})/I_3(\frac{1}{6}) = -\frac{54}{11}$. Then

$$b_{10} = P(0, b_{20}, b_{30}) = P\left(\frac{1}{6}, b_{20}, b_{30}\right) = 0.$$

Further, by Lemma 3.4 and (3.29) we have

$$P'_h(0, b_{20}, b_{30}) = \frac{1}{2}(3 + \delta_{20}) < 0,$$

$$\lim_{h \to \frac{1}{6}} \frac{P'_h(h, b_{20}, b_{30})}{T_h} = \frac{\delta_{20}}{I_1(\frac{1}{6})} < 0,$$

$$P\left(\frac{1}{6}, b_2, b_3\right) = -\frac{I_3(\frac{1}{6})}{I_1(\frac{1}{6})}(\delta_2 - \delta_{20}).$$

Denote by Γ^0 and Γ^* respectively the graph of the function $P(h, b_2, b_3)$ on the (b_1, h) plane for $\delta_2 = \delta_{20}$ and $\delta_2 = \delta_2^*$, where $\delta_2^* < \delta_{20}$ with $|\delta_2^* - \delta_{20}|$ small. See Fig. 12.

It is clear that for $\delta_1^* < 0$ and $|\delta_1^*|$ sufficiently small, the line $b_1 = \delta_1^*$ and Γ^*: $b_1 = P(h, -3, \delta_2^*)$ have at least 3 intersection points. Then the conclusion follows easily.

3.3. *Near-Hamiltonian polynomial systems*

We now give an important application of Theorem 3.3 to polynomial systems.

Consider a near-Hamiltonian polynomial system of the form

$$\begin{aligned} \dot{x} &= H_y(x, y, \mu) + \varepsilon p(x, y, a), \\ \dot{y} &= -H_x(x, y, \mu) + \varepsilon q(x, y, a), \end{aligned} \tag{3.32}$$

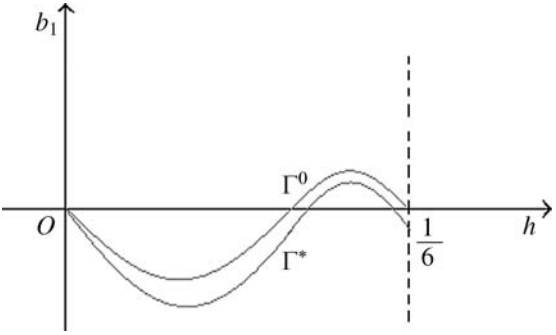

Fig. 12. Curves Γ^0 and Γ^*.

where

$$H(x,y,\mu)=\frac{1}{2}\left(x^2+y^2\right)+\sum_{i+j=3}^{m} h_{ij}x^i y^j,\quad m\geqslant 3,$$

$$p(x,y,a)=\sum_{i+j=1}^{n} a_{ij}x^i y^j,\qquad q(x,y,a)=\sum_{i+j=1}^{n} b_{ij}x^i y^j,$$

and $\mu=\{h_{ij}\}\in\mathbb{R}^r$, $r=\frac{1}{2}(m+1)(m+2)-6$, $a=\{a_{ij},b_{ij}\}\in\mathbb{R}^{n^2+3n}$, $n\geqslant 2$. For each μ, there exists $\beta=\beta(\mu)\in(0,+\infty]$ such that for $h\in(0,\beta)$ the equation $H(x,y,\mu)=h$ defines a smooth closed curve L_h which surrounds a unique singular point (the origin) of the system (3.32) ($\varepsilon=0$). By (3.4) we can write

$$M(h,a)=\sum_{i+j=0}^{n-1} c_{ij}I_{ij}(h)=\sum_{j=1}^{k} b_j I_j(h),$$

where

$$I_{ij}=\iint_{H\leqslant h} x^i y^j\,\mathrm{d}x\,\mathrm{d}y,$$

$$\{I_1,\dots,I_k\}=\{I_{ij},\ 0\leqslant i+j\leqslant n-1\},\quad I_1=I_{00},$$

$$\{b_1,\dots,b_k\}=\{c_{ij},\ 0\leqslant i+j\leqslant n-1\},\quad k=\frac{1}{2}n(n+1).$$

Denote by $W(h,\mu)$ the Wronskian defined by (3.9). Then the equation $W(0,\mu)=0$ defines an $(r-1)$-dimensional surface $\Sigma_{r-1}^{(1)}$ in $\mathbb{R}^r$ and the equations $W(h,\mu)=W_h'(h,\mu)=0$ with $0\leqslant h<\beta(\mu)$ define another $(r-1)$-dimensional surface $\Sigma_{r-1}^{(2)}$. Let

$$B_r=\mathbb{R}^r-\Sigma_{r-1}^{(1)}-\Sigma_{r-1}^{(2)}.$$

Then B_r is an open set in $\mathbb{R}^r$ with boundary $\Sigma_{r-1}^{(1)} \cup \Sigma_{r-1}^{(2)}$. For each $\mu \in B_r$, we have

$$W(0,\mu) \neq 0, \qquad \left|W(h,\mu)\right| + \left|W_h'(h,\mu)\right| \neq 0, \quad h \in [0,\beta).$$

Note that for each $\mu \in B_r$ and $\bar{h} \in (0,\beta)$, the analytic function $W(h,\mu)$ has only finitely many zeros $h_1,\ldots,h_l$ on $(0,\bar{h}]$. Then by Theorem 3.3 we have immediately:

THEOREM 3.7. *There exists an open set B_r in $\mathbb{R}^r$ whose boundary consists of $r-1$ dimensional surfaces such that for each $\mu \in B_r$, and $\bar{h} \in (0,\beta)$ there may exist constants $0 < h_1 < \cdots < h_l$ with $l \geqslant 0$ such that*

(i) *for $h \in [0,\bar{h}] - \{h_1,\ldots,h_l\}$, Eq.* (3.32) *has cyclicity $\frac{1}{2}n(n+1)-1$ at L_h;*

(ii) *for $h \in \{h_1,\ldots,h_l\}$, Eq.* (3.32) *has cyclicity $\frac{1}{2}n(n+1)$ at L_h.*

In particular, for each $\mu \in B_r$, Eq. (3.32) *has Hopf cyclicity $\frac{1}{2}n(n+1)-1$ at the origin.*

Roughly speaking, for almost all $\mu \in \mathbb{R}^r$, Eq. (3.32) has cyclicity $\frac{1}{2}n(n+1)-1$ or $\frac{1}{2}n(n+1)$ at each L_h with $h \in [0,\beta)$.

REMARK 3.3. It is easy to see that in some cases, Theorem 3.7 is still valid if μ is a vector parameter of dimension r with $r < \frac{1}{2}(m+1)(m+2)-6$.

As an application, let us consider quadratic systems. By Ye et al. [117], a quadratic system having a focus or center can be changed into the form

$$\begin{aligned}\dot{x} &= -y + \delta x + lx^2 + mxy + ny^2,\\ \dot{y} &= x(1 + ax + by).\end{aligned}$$

The system is Hamiltonian if and only if $\delta = m = b + 2l = 0$. Then taking $\delta = \varepsilon\delta_1$, $m = \varepsilon m_1$, $b = -2l_0 + \varepsilon b_1$, $l = l_0 + \varepsilon l_1$, $a = a_0 + \varepsilon a_1$, it becomes

$$\begin{aligned}\dot{x} &= H_y + \varepsilon\left(\delta_1 x + l_1 x^2 + m_1 xy + n_1 y^2\right),\\ \dot{y} &= -H_x + \varepsilon\left(a_1 x^2 + b_1 xy\right),\end{aligned} \tag{3.33}$$

where

$$H(x,y) = -\frac{1}{2}\left(x^2+y^2\right) + l_0 x^2 y + \frac{1}{3}n_0 y^3 - \frac{1}{3}a_0 x^3.$$

For (3.33), we have

$$M(h) = \delta_1 I_1(h) + \bar{b}_1 I_2(h) + m_1 I_3(h), \quad \bar{b}_1 = b_1 + 2l_1,$$

where

$$\begin{aligned}I_1(h) &= \iint_{-H\leqslant h} \mathrm{d}x\,\mathrm{d}y, \quad I_2(h) = \iint_{-H\leqslant h} x\,\mathrm{d}x\,\mathrm{d}y,\\ I_3(h) &= \iint_{-H\leqslant h} y\,\mathrm{d}x\,\mathrm{d}y, \quad h \in [0,\beta).\end{aligned}$$

By [117], up to a positive constant, the first four focus values of the origin can be taken as

$$W_0 = \varepsilon V_0, \qquad W_i = \varepsilon V_i + \mathrm{O}\big(\varepsilon^2\big), \quad i = 1, 2, 3,$$

where

$$\begin{aligned} &V_0 = \delta_1, \quad V_1 = m_1(n_0 + l_0) - a_0\bar{b}_1, \\ &V_2 = 5m_1a_0^2\big[(l_0 + n_0)^2(n_0 - 2l_0) - a_0^2n_0\big]. \end{aligned}$$

Thus,

$$\det \frac{\partial(V_0, V_1, V_2)}{\partial(\delta_1, \bar{b}_1, m_1)} = -5a_0^3\big[(l_0 + n_0)^2(n_0 - 2l_0) - a_0^2n_0\big].$$

Hence, by Lemma 2.9 and (3.12), it is easy to see that

$$W(0, a_0, l_0, n_0) = N_0a_0^3\big[(l_0 + n_0)^2(n_0 - 2l_0) - a_0^2n_0\big], \qquad N_0 \neq 0.$$

Then from the discussion before Theorem 3.7 it follows that for any $(a_0, l_0, n_0) \in \mathbb{R}^3$ satisfying

$$a_0\big[(l_0 + n_0)^2(n_0 - 2l_0) - a_0^2n_0\big] \neq 0,$$

the Hopf cyclicity of (3.33) at the origin is 2.

3.4. *Homoclinic bifurcation*

In the rest of the chapter, we introduce a way to find limit cycles in a neighborhood of the homoclinic loop L_β.

As a preliminary, we first discuss the stability of an isolated homoclinic loop. Consider a C^∞ planar system of the form

$$\dot{x} = f(x, y), \qquad \dot{y} = g(x, y). \tag{3.34}$$

Suppose that (3.34) has a homoclinic loop L with a hyperbolic saddle. Assume that the saddle is at the origin. Then on the stability of L we have

LEMMA 3.5. *Let*

$$c_1 = (f_x + g_y)(0), \qquad c_2 = \oint_L (f_x + g_y - c_1)\,\mathrm{d}t. \tag{3.35}$$

Then L is stable (*unstable*) *if* $c_1 < 0$, *or* $c_1 = 0$, $c_2 < 0$ ($c_1 > 0$, *or* $c_1 = 0$, $c_2 > 0$).

For a proof of the lemma, see Han [47,51], Han and Chen [57], and Feng and Qian [27].

Further, let $c_1 = c_2 = 0$. We can assume the functions f and g have the following form:

$$f(x, y) = \lambda x + \mathrm{O}\bigl(|x, y|^2\bigr), \quad g(x, y) = -\lambda y + \mathrm{O}\bigl(|x, y|^2\bigr), \quad \lambda > 0.$$

In this case, let

$$c_3 = \frac{1}{2\lambda}\left[f_{xxy} + g_{xyy} - \frac{1}{\lambda}(f_{xx} f_{xy} - g_{xy} g_{yy}) \right]\Bigg|_{x=y=0}, \tag{3.36}$$

which is called the first saddle value of (3.34) at the origin.

If f and g satisfy

$$f(x, y) = \lambda y + \mathrm{O}\bigl(|x, y|^2\bigr), \qquad g(x, y) = \lambda x + \mathrm{O}\bigl(|x, y|^2\bigr),$$

then, instead of (3.36), let

$$\begin{aligned} c_3 = -\frac{1}{2\lambda}\biggl[& f_{xxx} - f_{xyy} + g_{xxy} - g_{yyy} + \frac{1}{\lambda}\bigl(f_{xy}(f_{yy} - f_{xx}) \\ & + g_{xy}(g_{yy} - g_{xx}) - f_{xx} g_{xx} + f_{yy} g_{yy}\bigr)\biggr]\Bigg|_{x=y=0}. \end{aligned} \tag{3.37}$$

Then we have the following lemma obtained by Han, Hu and Liu [58].

LEMMA 3.6. *Let* $c_1 = c_2 = 0$, *and* $c_3 \neq 0$. *Then* L *is stable if and only if one of the following occurs*:

(i) $c_3 < 0$, *a Poincaré map is well-defined near inside* L *and* L *is oriented anti-clockwise*;
(ii) $c_3 < 0$, *a Poincaré map is well-defined near outside* L *and* L *is oriented clockwise*;
(iii) $c_3 > 0$, *a Poincaré map is well-defined near outside* L *and* L *is oriented anti-clockwise*;
(iv) $c_3 > 0$, *a Poincaré map is well-defined near inside* L *and* L *is oriented clockwise.*

We remark that the formula (3.37) can be obtained from (3.36) by introducing a liner transformation $x = \frac{1}{\sqrt{2}}(u - v)$ and $y = \frac{1}{\sqrt{2}}(u + v)$ where u and v are new variables.

Going back to (3.1) we introduce the following four functions:

$$\begin{aligned} d_0(\delta) &= \oint_{L_\beta} (q\,\mathrm{d}x - p\,\mathrm{d}y)\Bigg|_{\varepsilon=0} = M(\beta, \delta), \\ d_1(\delta) &= (p_x + q_y)(S, 0, \delta), \\ d_2(\delta) &= \oint_{L_\beta} \bigl[p_x + q_y - d_1(\delta)\bigr]\,\mathrm{d}t, \\ d_3(\delta) &= \frac{\partial c_3}{\partial \varepsilon}(\varepsilon, \delta)\Bigg|_{\varepsilon=0}, \end{aligned} \tag{3.38}$$

where c_3 is obtained by (3.36) or (3.37).

The following theorem was obtained by Han [43].

THEOREM 3.8. (i) *Let there exist* $\delta_0 = (\delta_{10}, \dots, \delta_{m0}) \in D$, $m \geqslant 2$ *such that*

$$d_0(\delta_0) = d_1(\delta_0) = 0, \qquad d_2(\delta_0) \neq 0, \qquad \det \frac{\partial(d_0, d_1)}{\partial(\delta_1, \delta_2)}(\delta_0) \neq 0.$$

Then for any $\varepsilon_0 > 0$ *and neighborhood* U *of* δ_0 *there exists an open subset* $V_\varepsilon \subset U$ *for* $0 < \varepsilon < \varepsilon_0$ *such that Eq.* (3.1) *has* 2 *limit cycles near* L_β *for* $a \in V_\varepsilon$.

(ii) *Let there exist* $\delta_0 = (\delta_{10}, \dots, \delta_{m0}) \in D$, $m \geqslant 3$, *such that*

$$d_i(\delta_0) = 0, \quad i = 0, 1, 2, \qquad d_3(\delta_0) \neq 0, \qquad \det \frac{\partial(d_0, d_1, d_2)}{\partial(\delta_1, \delta_2, \delta_3)}(\delta_0) \neq 0.$$

Then for any $\varepsilon_0 > 0$ *and neighborhood* U *of* δ_0 *there exists an open subset* $V_\varepsilon \subset U$ *for* $0 < \varepsilon < \varepsilon_0$ *such that Eq.* (3.1) *has* 3 *limit cycles near* L_β *for* $a \in V_\varepsilon$.

We briefly outline the proof of the first conclusion. For definiteness, suppose L_β is oriented clockwise and the Poincaré map is well defined inside it as before. For $\varepsilon > 0$ small a unique saddle S_ε near S and two separatrices L_ε^u and L_ε^s near L_β exist. The directed distance between L_ε^s and L_ε^u on a cross section is given by (see [14,51,112])

$$d(\varepsilon, \delta) = \varepsilon N\big[d_0(\delta) + \mathrm{O}(\varepsilon)\big], \quad N > 0.$$

By the assumption, we can suppose $d'_{00} = \frac{\partial d_0}{\partial \delta_1}(\delta_0) \neq 0$. The implicit function theorem implies that a unique function $\delta_1 = \varphi_1(\varepsilon, \delta_2, \dots, \delta_m) = \varphi_{10}(\delta_2, \dots, \delta_m) + \mathrm{O}(\varepsilon)$ exists such that for $\varepsilon > 0$ and $|\delta - \delta_0|$ small $d(\varepsilon, \delta) \geqslant 0$ if and only if $d'_{00}[\delta_1 - \varphi_1] \geqslant 0$. Hence, a homoclinic loop L_ε^* appears near L_β if $\delta_1 = \varphi_1$.

Let $\delta_1 = \varphi_1$ and define

$$c_1(\varepsilon, \delta_2, \dots, \delta_m) = \varepsilon(p_x + q_y)(S_\varepsilon, 0, \delta) = \varepsilon\big[c_{10}(\delta_2, \dots, \delta_m) + \mathrm{O}(\varepsilon)\big],$$

where

$$c_{10} = (p_x + q_y)(S, 0, \delta)|_{\delta_1 = \varphi_{10}}.$$

Then our assumption implies that

$$c_{10}(\delta_{20}, \dots, \delta_{m0}) = 0, \qquad d'_{10} = \frac{\partial c_{10}}{\partial \delta_2}(\delta_{20}, \dots, \delta_{m0}) \neq 0.$$

Thus a unique function $\delta_2 = \varphi_2(\varepsilon, \delta_3, \dots, \delta_m) = \varphi_{20}(\delta_3, \dots, \delta_m) + \mathrm{O}(\varepsilon)$ exists such that

$$c_1(\varepsilon, \delta_2, \dots, \delta_m) \geqslant 0 \quad \text{if and only if} \quad d'_{10}[\delta_2 - \varphi_2] \geqslant 0.$$

Let $\delta_1 = \varphi_1, \delta_2 = \varphi_2$ and define

$$c_2(\varepsilon, \delta_3, \ldots, \delta_m) = \varepsilon \oint_{L_\varepsilon^*} (p_x + q_y)\,\mathrm{d}t = \varepsilon\big[c_{20}(\delta_3, \ldots, \delta_m) + \mathrm{O}(\varepsilon)\big],$$

where

$$c_{20}(\delta_3, \ldots, \delta_m) = \oint_{L_\beta} (p_x + q_y)|_{\delta_1=\varphi_{10},\, \delta_2=\varphi_{20}}\,\mathrm{d}t.$$

It is easy to see that

$$c_{20}(\delta_{30}, \ldots, \delta_{m0}) = d_2(\delta_0) \neq 0.$$

Without loss of generality, suppose $d_2(\delta_0) > 0$. Then for $\varepsilon > 0$, $\delta_1 = \varphi_1, \delta_2 = \varphi_2$ and $\varepsilon + |\delta - \delta_0|$ small L_ε^* is unstable by Lemma 3.6. Fix $\varepsilon > 0$ and δ_j near δ_{j0} for $j = 3, \ldots, m$, and vary δ_1 and δ_2 such that

$$\delta_1 = \varphi_1, \qquad 0 < |\delta_2 - \varphi_2| \ll 1, \qquad c_1(\varepsilon, \delta_2, \ldots, \delta_m) < 0.$$

Then, L_ε^* has changed its stability from unstable into stable and therefore an unstable limit cycle has appeared near it at the same time. Next, noting that we have assumed that L_β is oriented clockwise and the Poincaré map is well-defined inside it, we then change δ_1 such that $0 < |\delta_1 - \varphi_1| \ll |\delta_2 - \varphi_2|$, $d(\varepsilon, \delta) < 0$. Clearly, L_ε^* has broken and a stable limit cycle has appeared. Therefore, 2 limit cycles can appear near L_β.

We can summarize the method used above into 3 steps:

1. For $\varepsilon > 0$ fixed, a homoclinic loop L_ε^* appears for δ on a codimension 1 surface in $\mathbb{R}^m$ when $d(\varepsilon, \delta) = 0$.
2. Keep L_ε^* to appear and study its stability and then change the stability of L_ε^* in turn to produce limit cycles.
3. Find a final limit cycle by making the homoclinic loop broken.

This method was first used by Han [43] and then developed by Han and Chen [57] and Han, Hu and Liu [58] to study the number of limit cycles near a double homoclinic loop.

General theorems like Theorem 3.8 on double homoclinic bifurcations can be found in Han and Zhang [71]. Interesting applications of the method to quadratic and cubic systems et al. for the existence limit cycles are given in [65–68,70,72,122–126].

EXAMPLE 3.7. Consider

$$\begin{aligned} \dot{x} &= y - \varepsilon\big(a_1 x + a_2 x^2 + x^4\big), \\ \dot{y} &= x - x^2. \end{aligned} \tag{3.39}$$

For $\varepsilon = 0$, (3.39) has a first integral of the form

$$H(x, y) = \frac{1}{2}\big(y^2 - x^2\big) + \frac{1}{3}x^3,$$

which gives a family of periodic orbits

$$L_h\colon\ H(x,y)=h,\quad -\frac{1}{6}<h<0.$$

The limit of L_h as $h\to 0$ is a homoclinic loop L_0. We can prove that (3.39) has 2 limit cycles near L_0 for some (a_1,a_2).

In fact, for (3.39) we have

$$d_0(a_1,a_2)=-a_1I_{00}-2a_2I_{01}-4I_{03},$$

where

$$I_{0j}=\oint_{L_0}x^jy\,\mathrm{d}x=2\int_0^{3/2}x^{j+1}\sqrt{1-\frac{2}{3}x}\,\mathrm{d}x,\quad j=0,1,3.$$

It easy to get that

$$I_{00}=\frac{6}{5},\qquad I_{01}=\frac{36}{35},\qquad I_{03}=\frac{72}{77}I_{00}.$$

Thus,

$$d_0(a_1,a_2)=-I_{00}\left[a_1+\frac{12}{7}a_2+\frac{288}{77}\right].$$

By (3.38), we have further

$$\begin{aligned}d_1(a_1,a_2)&=-a_1,\\ d_2(a_1,a_2)&=-\oint_{L_0}\left(2a_2x+4x^3\right)\mathrm{d}t\\ &=-2\int_0^{3/2}\frac{2a_2x+4x^3}{\sqrt{1-\frac{2}{3}x}}\,\mathrm{d}x=-6\left[2a_2+\frac{24}{5}\right].\end{aligned}$$

Hence, if $a_1=0, a_2=-\frac{24}{11}$, then

$$d_0=d_1=0,\qquad d_2\neq 0.$$

It follows from Theorem 2.8 that Eq. (3.39) has 2 limit cycles for $\varepsilon>0$ small and some (a_1,a_2) near $(0,-\frac{24}{11})$.

From Han [51] we know Eq. (3.39) has at most 2 limit cycles on the plane for all $\varepsilon>0$ small and (a_1,a_2) bounded.

REMARK 3.4. Study of the number of limit cycles for near-Hamiltonian systems has been a significant and important part of bifurcation theory for decades. Most results can be divided into two aspects. One is to give a lower bound of the number for a given system with parameters. In other words, this aspect mainly concentrates on finding limit cycles as many as possible by choosing suitable parameters. The other is to study the maximal number of limit cycles and give an upper bound of it. In this section we mainly concern with the theory and methods in the first aspect. Theorem 3.1 is well known as Poincaré–Pontryagin–Andronov theorem. The formula in Lemma 3.2 was first obtained by Han [39]. Theorems 3.2, 3.3 and 3.7 are just recently obtained by Han, Chen and Sun [56]. Theorem 3.4 is from Han [51]. Results in Lemma 3.3 were given by Luo, Han and Zhu [100]. Here we present a new and simple proof. Conclusions of Lemma 3.4 were first established in Han and Ye [69]. The homoclinic bifurcation under the condition of Lemma 3.6 was studied in Zhu [130] in detail. Theorems 3.5 and 3.6 are new and obtained by the author. There have been many interesting results in the second aspect on the estimate of an upper bound for the number of limit cycles planar systems. For the theory and methods on this aspect, the reader can consult [13,15–18,23–26,42–44,49,74,76,83,107,109,115–118,127, 128]. For the bifurcation of periodic solutions of higher dimensional systems, see [14,16, 35,37,39,41,51–53,111,112,131].

1. Introduction

Studies of single differential equations with state-dependent delayed or advanced arguments go back at least to Poisson [181], but as an object of a broader mathematical activity the area is rather young.

Most work during the past 50 years is devoted to equations with state-dependent delays, which arise as models in applications. A prominent example is the two-body problem of electrodynamics, which remained a mathematical terra incognita until R.D. Driver's work began to appear in the sixties of the last century.

The present survey reports about the more recent work on equations with state-dependent delays, with emphasis on particular models and on the emerging theory from the dynamical systems point of view. Several new results are presented. It will also become obvious that challenging problems remain to be solved.

State-dependent delays were addressed earlier in survey papers on the larger area of functional differential equations, notably by Halanay and Yorke [94] and Myshkis [165]. It is tempting to borrow as a motto from Halanay and Yorke [94] their nice statement

> *This … proved once more, if necessary, that the delay existing at the present time between the moment results are obtained and the moment of publication (as well as the great number of publications which are very difficult to follow) makes it necessary to present from time to time such reports on yet unpublished results and unsolved problems.*

The simplest example of a differential equation with constant delay is the linear equation

$$y'(t) = ay(t-h)$$

with the fixed delay $h > 0$ and a parameter $a \in \mathbb{R}$. Analogues with state-dependent delay like

$$x'(t) = ax\big(t - r\big(x(t)\big)\big),$$

with a bounded delay map $r : \mathbb{R} \to [0, h]$, are already nonlinear in general. Both equations can be written in the same general form

$$x'(t) = f(x_t) \tag{1.0.1}$$

of a delay differential equation. Here $f : U \to \mathbb{R}^n$ is defined on a subset U of the set $(\mathbb{R}^n)^{[-h,0]}$ of all functions $\phi : [-h, 0] \to \mathbb{R}^n$. The *solution segment* $x_t : [-h, 0] \to \mathbb{R}^n$ is given by

$$x_t(s) = x(t+s), \quad -h \leqslant s \leqslant 0.$$

In case of the examples above, we have

$$n = 1, \quad U = \mathbb{R}^{[-h,0]}, \quad f(\phi) = a\phi(-h) \quad \text{and} \quad f(\phi) = a\phi\big(-r\big(\phi(0)\big)\big),$$

respectively.

The maps $f : U \to \mathbb{R}^n$ describing equations with state-dependent delay have in general less smoothness properties than those representing equations with constant delay, and the theory of Retarded Functional Differential Equations (RFDEs) which has been developed since the fifties of the last century (see, e.g., [54,98]) is not applicable to equations with state-dependent delay. This concerns already basic questions of existence, uniqueness and smooth dependence on initial data for the initial value problem (IVP)

$$x'(t) = f(x_t), \quad x_{t_0} = \phi \tag{1.0.2}$$

which for data $\phi \in U$ and for $t_0 \in \mathbb{R}$ is associated with Eq. (1.0.1). When in the sequel we speak of a solution $x : [t_0 - h, T) \to \mathbb{R}^n$, $t_0 < T \leqslant \infty$, to the IVP (1.0.2) it is always understood that x at least satisfies

$$x_t \in U \quad \text{for all } t \in [0, T), \quad x_{t_0} = \phi,$$

and that x is differentiable on (t_0, T) with

$$x'(t) = f(x_t) \quad \text{for all } t \in (0, T).$$

In Section 3 solutions of well-posed IVPs will even be continuously differentiable.

The following Section 2 describes examples of differential equations with state-dependent delays which arise in physics, automatic control, neural networks, infectious diseases, population growth, and cell production. Some of these models differ considerably from others, and most of them do not look simple. Typically the delay is not given explicitly as a function of what seems to be the natural state variable; the delay may be defined implicitly by a functional, integral or differential equation and should often be considered as part of the state variables.

Modelling systems with state-dependent delays seems to require extra care, perhaps because there is not much experience with this phenomenon. We tried to avoid models for which as yet no consistent motivation can be given.

The models in Section 2 indicate the types of equations to which the subsequent sections are confined. Not covered are, for example, nonautonomous systems, delays of the form $r = r(t) = a\,t + b\,x(t)$ or $r(t) = at + bx''(t)$ like in [186–188], and constructions of explicit solutions as in [104]. Also we do not say much about state-dependent delays in control theory. Early work in this area is found in [80–82,160].

Section 3 presents a framework for the study of the IVP (1.0.2). We analyze how state-dependent delays prevent the IVP (1.0.2) from being well-posed on open subsets U of familiar Banach spaces, and see that under mild smoothness hypotheses the IVP (1.0.2) *is* well-posed for data only in a submanifold of finite codimension. This *solution manifold* is given by the equation considered and generalizes the familiar domain of the generator of the semigroup given by a linear autonomous RFDE (as in [54,98]). On the solution manifold the IVP (1.0.2) with $t_0 = 0$ defines a semiflow of continuously differentiable solution operators. This resolves the problem of linearization for equations with state-dependent delay, which had been pointed out earlier by Cooke and Huang [48]. The widely known heuristic technique of *freezing the delay at equilibrium and then linearizing the resulting*

RFDE, often skilfully applied, can now be understood in terms of the true linearization. It is clarified why familiar characteristic equations for linear autonomous RFDEs can be used to analyze local dynamics generated by differential equations with state-dependent delay.

At stationary points the continuously differentiable solution operators have local center, stable, and unstable manifolds. It is shown that these stable and unstable manifolds of maps yield local stable and unstable manifolds also for the semiflow. In particular there is a convenient Principle of Linearized Stability. Center manifolds for the semiflow can not be immediately obtained as just described; they are constructed in Section 4.

Examples to which the results of Section 3 apply are given in [206,208]; for the proof in [208] that hyperbolic stable periodic orbits exist the smoothness results of Section 3 are indispensable. Most other work about which we report was accomplished before the basic theory of Section 3 was developed; some further work was done in parallel. We do not attempt to present these other results in the framework of Section 3. In fact, for many models it remains to be studied whether they fit into this framework or not.

In Section 4 a new result is proved, namely existence of Lipschitz continuous local center manifolds for the semiflow found in Section 3, at stationary points. The more technical proof that these center manifolds actually are continuously differentiable will appear elsewhere. An important open problem is to obtain more smoothness, as it was established for local unstable manifolds [129].

Section 5 is about local Hopf bifurcation, i.e., about the appearance of small periodic orbits close to a stationary point when a parameter in the underlying differential equation is varied and passes a critical value. We state a Hopf bifurcation theorem recently obtained by M. Eichmann [65], which seems to be the first such result for differential equations with state-dependent delays.

Section 6 presents results about differentiability of solutions with respect to parameters and initial data, for a certain class of nonautonomous differential equations with state-dependent delay. The framework is different from the one developed in Section 3. The IVP is considered for Lipschitz continuous initial data, and a quasi-normed space derived from Sobolev spaces turns out to be useful for studying differentiability under relaxed smoothness assumptions, which may be convenient for applications.

Section 7 deals with periodic orbits. The search for periodic solutions has been an important topic in the study of nonlinear autonomous delay differential equations since the sixties of the last century. By now, several methods have been developed in this area. The most general results on existence and global bifurcation employ fixed point theorems and the fixed point index. Others are based on the study of 2-dimensional invariant sets, or on Poincaré–Bendixson type analysis of plane curves which are obtained from evaluations like $x_t \mapsto (x(t), x(t-1))$ along certain solutions. There are local and global Hopf bifurcation theorems for RFDEs, the Fuller index counting periodic orbits is used, and certain symmetric periodic solutions can be obtained from associated ordinary differential systems. Not all approaches mentioned here have been tried for equations with state-dependent delays, which cause complications. We describe results which use the topological concept of ejectivity, and an approach which yields stable periodic orbits. Let us add here that topological tools (fixed point theorems, degree, coincidence degree) have also been employed to prove existence of periodic solutions to nonautonomous, *periodic* differential equations with state-dependent delay [43,138,139,221,225]; related work on nonautonomous equations is found in [50,55].

The topic of Section 8 is limiting behaviour with respect to the independent variable and with respect to parameters. Section 8.1 presents a study of a two-dimensional attractor with periodic orbits, which extends a part of a result for equations with constant delay. Section 8.2 reports about results of Mallet-Paret and Nussbaum on the precise asymptotic shape of periodic solutions in a singular perturbation problem. These results are genuine for equations with state-dependent delay, and involve work on unusual eigenvalue problems for so-called *max-plus operators*. Section 8.3 describes an approach to periodic solutions in case of small delay. Section 8.4 contains an application of the monotone dynamical systems theory which yields a generic convergence result, and Section 8.5 comments on further results about stability and oscillation properties.

Section 9 deals with numerical methods. The study of numerical approximation of solutions to differential equations with state-dependent delay goes back at least to the mid-sixties of the last century, and since then it has been an intensively investigated area. The section begins with a brief summary of continuous Runge–Kutta methods for ordinary differential equations and reports about modifications and extensions which are necessary in case of state-dependent delays.

Let us mention here a few out of many open questions, in addition to those addressed in the subsequent sections. Do equations with state-dependent delay generate semiflows with better smoothness properties than obtained in Section 3, on suitable invariant sets? The results from [129] on unstable manifolds point in this direction. A suspicion is that periodic solutions of equations with state-dependent delay may have stronger stability properties than their counterparts in related equations with constant delay. Can this be made precise and established, for suitable classes of equations? Complicated motion, like chaos, has not yet been rigorously shown to exist for equations with state-dependent delay. Very little is known about the general two-body problem of electrodynamics with two charged particles in a 3-dimension configuration space. Vanishing state-dependent delays, like in a collision in the two-body problem, are also limiting cases of advanced arguments; this indicates that a better understanding of more general differential equations with both delayed and advanced state-dependent arguments may be needed.

It is convenient to end this introduction with notation, for function spaces which occur frequently in the sequel. The Banach spaces of continuous, Lipschitz continuous, and continuously differentiable maps $\phi : [-h, 0] \to \mathbb{R}^n$ are denoted by

$$C = C\bigl([-h,0];\mathbb{R}^n\bigr), \quad C^{0,1} = C^{0,1}\bigl([-h,0];\mathbb{R}^n\bigr), \quad \text{and}$$
$$C^1 = C^1\bigl([-h,0];\mathbb{R}^n\bigr),$$

respectively. The norms on these spaces are given by

$$\|\phi\|_C = \max_{-h\leqslant t\leqslant 0}\bigl|\phi(t)\bigr|, \quad \|\phi\|_{C^{0,1}} = \|\phi\|_C + \sup_{t\neq s}\frac{|\phi(t)-\phi(s)|}{|t-s|},$$
$$\|\phi\|_{C^1} = \|\phi\|_C + \bigl\|\phi'\bigr\|_C,$$

respectively.

If X and Y are real or complex Banach spaces then $L(X, Y)$ denotes the Banach space of continuous linear mappings $T : X \to Y$, with the norm given by $\|T\| = \sup_{\|x\| \leqslant 1} \|Tx\|$.

2. Models and applications

A remark in [206] says that *state-dependent delays arise in various circumstances, but it seems not obvious how to single out a tractable class of equations which contains a large set of examples which are well motivated.* The difficulty of singling out a tractable class of equations to include many interesting models may prove to be an extremely valuable source to stimulate new mathematical techniques and theories. In this section we describe differential equations with state-dependent delay that arise from electrodynamics, automatic and remote control, machine cutting, neural networks, population biology, mathematical epidemiology and economics.

2.1. *A two-body problem of classical electrodynamics*

In Driver [58] (see also [57,59]), a mathematical model for a two-body problem of classical electrodynamics incorporating retarded interaction is proposed and analyzed. He considers the motion for two charged particles moving along the x-axis and substituted the expressions for the field of a moving charge, calculated from the Liénard–Wiechert potential, into the Lorentz–Abraham force law. Radiation reaction is omitted, but time delays are incorporated due to the finite speed of propagation, c, of electrical effects. As a result, the model is a system of delay differential equations involving time delays, which depend on the unknown trajectories. From this model and after some analysis, he obtains a system of six delay-differential equations for the evolution of the states, the velocities and the time delays.

To describe his model, we denote by $x_i(t)$ $(i = 1, 2)$ the positions of the two point charges on the axis in a given inertial system at time t, the time of an observer in that system. Let $v_i(t) = x_i'(t)$ $(i = 1, 2)$ be the velocities of the charges. As mentioned above, we omit radiation reaction but allow an external electric field, $E_{\text{ext}}(t, x)$, in the x-direction, that is assumed to be continuous over some open set D in the (t, x)-plane. Then the equation of motion of charge i is

$$\frac{m_i v_i'(t)}{[1 - v_i^2(t)/c^2]^{3/2}} = q_i E_j\bigl(t, x_i(t)\bigr) + q_i E_{\text{ext}}\bigl(t, x_i(t)\bigr), \quad i, j \in \{1, 2\},\ j \neq i, \tag{2.1.1}$$

where m_i is the rest mass and q_i is the magnitude of charge i, c is the speed of light, and $E_j(t, x)$ is the electric field at (t, x) due to other charge $j \neq i$. The magnetic field of charge j is not involved in this one-dimensional case.

The field at time t and at the point $x_i(t)$ produced by charge j is assumed to be that computed from the Liénard–Wiechert potentials. The expression for this field involves a time lag, $t-\tau_{ji}$, representing the instant at which a light signal would have to leave charge j in order to arrive at $x_i(t)$ at the instant t. Therefore, the delay $\tau_{ji}(t)$ must be a solution of the functional equation

$$\tau_{ji}(t)=\bigl|x_i(t)-x_j\bigl(t-\tau_{ji}(t)\bigr)\bigr|/c. \tag{2.1.2}$$

Clearly, $\tau_{ji}(t)$ cannot be written explicitly.

Because of the occurrence of time delays in the model equation (2.1.1), one needs to specify initial trajectories of the two charges over some appropriate interval $[\alpha, t_0]$. Consider now those initial trajectories and their extensions $(x_1(t), x_2(t))$ defined on some interval $[\alpha, \beta)$, where $\beta > t_0$, such that

(a) each $x_i'(t)$ is continuous and $|x_i'(t)| < c$ for all $t \in [\alpha, \beta)$;
(b) $x_2(t) > x_1(t)$ and $(t, x_i(t)) \in D$ for all $t \in [t_0, \beta)$;
(c) the two functional equations $\tau_{ji}^0 = |x_i(t_0) - x_j(t_0 - \tau_{ji}^0)|/c$ have solutions τ_{ji}^0, $i \neq j$, $i, j \in \{1, 2\}$.

Then Driver proves that $(x_1(t), x_2(t))$ is a solution of (2.1.1)–(2.1.2) if and only if it satisfies the following system of six delay differential equations for $t \in (t_0, \beta)$:

$$\begin{cases} x_i'(t)=v_i(t), \\ \tau_{ji}'(t)=\dfrac{(-1)^i v_i(t)-(-1)^i v_j(t-\tau_{ji}(t))}{c-(-1)^i v_j(t-\tau_{ji}(t))}, \\ \dfrac{v_i'(t)}{[1-v_i^2(t)/c^2]^{3/2}}=\dfrac{(-1)^i a_i c}{\tau_{ji}^2(t)}\cdot\dfrac{c+(-1)^i v_j(t-\tau_{ji}(t))}{c-(-1)^i v_j(t-\tau_{ji}(t))}+q_i E_{\text{ext}}\bigl(t, x_i(t)\bigr)/m_i, \end{cases} \tag{2.1.3}$$

where $\tau_{ji}(t_0) = \tau_{ji}^0$, $a_i = q_1 q_2/(4\pi\epsilon_0 m_i c^3)$ (a constant, and in particular, ϵ_0 is the dielectric constant of free space), and $(i, j) = (1, 2)$ or $(2, 1)$.

It is shown in Driver [58] that if given initial trajectories satisfy condition (a) for $\alpha \leqslant t \leqslant t_0$, condition (b) at t_0, and condition (c), and if $E_{\text{ext}}(t, x)$ is Lipschitz continuous with respect to x in each compact subset of D and if the initial velocity of each particle is Lipschitz continuous, then a unique solution does exist. This solution can be continued as long as the charges do not collide ($\lim x_1(t) = \lim x_2(t)$ as t approaches the right endpoint of the maximal interval for existence) and neither $(t, x_1(t))$ nor $(t, x_2(t))$ approaches the boundary D.

We remark here that in Driver and Norris [64], the above Lipschitz continuity for the initial velocities is relaxed to the integrability of the initial velocity on $[\alpha, t_0]$. In Driver [61], one special case was given where the positions and velocities of the particles *at some instant* will determine the state of the system. More precisely, in this example of electrodynamic equations of motion, instantaneous values of positions and velocities of the particles will determine their trajectories, if the solutions are defined for all future time. This property was frequently conjectured, asserted, or implicitly assumed, as in Newtonian mechanics and as indicated by the long list of related references in Driver [61], but this property should not be expected for general electrodynamic equations.

In the case where $E_{\text{ext}}(t,x)=0$ for all $(t,x)\in\mathbb{R}^2$ and if $q_1q_2>0$ (two point charges of like sign), then $\lim_{t\to\infty}[x_2(t)-x_1(t)]=\infty$ and $|v_i(t)|\leqslant\bar{c}<c$ for all $t\geqslant\alpha$. This is a quite interesting result as it indicates that the delay $\tau_{ji}(t)$ may become unbounded, as such, one obtains a system of functional differential equation with unbounded state-dependent delays.

It is noted that if three-dimensional motions are considered, then one obtains a functional differential system of neutral type where the delays are dependent on the states, and the change rate of v_i at the current time also depends on its historical value $v_j'(t-\tau_{ji})$. More precisely, if we introduce a unit vector

$$u_i=\frac{x_i-x_j(t-\tau_{ji})}{c\tau_{ji}}$$

and a scalar quantity

$$\gamma_{ij}=1-\frac{1}{c}v_j(t-\tau_{ji})\cdot u_i$$

as Driver [62] does, where $\cdot$ indicates the dot or scalar product in $\mathbb{R}^3$ (note, of course, x_1, x_2 are now vectors in $\mathbb{R}^3$), then the Lorentz force law yields

$$v_i'(t)=\frac{q_i(1-|v_i|^2/c^2)^{1/2}}{m_i}\big[E_j+(v_i/c\cdot E_j)(u_i-v_i/c)-(v_i/c\cdot u_i)E_j\big], \tag{2.1.4}$$

where E_j is the retarded (vector-valued) electric field arriving at x_i at the instant t from particle j. This field, in $\mathbb{R}^3$, can be found from the Liénard–Weichert potentials as

$$\begin{aligned}E_j={}&\frac{kcq_j}{\tau_{ji}^2\gamma_{ij}^3}\big[u_i-v_i(t-\tau_{ji})/c\big]\big[1-|v_j|^2(t-\tau_{ji})\big]\\&+\frac{kq_j}{\tau_{ji}\gamma_{ij}^3}u_i\times\big(\big[u_i-v_j(t-\tau_{ji})/c\big]\times v_j'(t-\tau_{ji})\big),\end{aligned} \tag{2.1.5}$$

where $k>0$ is a constant depending on the units, and $\times$ indicates the vector cross product in $\mathbb{R}^3$. The dynamical adaptation for τ_{ji} is given by

$$\tau_{ji}'(t)=\frac{u_i\cdot[v_i-v_j(t-\tau_{ji})]}{c\gamma_{ij}}. \tag{2.1.6}$$

In the above discussions, the motion of each particle is influenced by the electromagnetic fields of the others, and due to the finite speed of the propagation of these fields, the model equations describing the motion of charged particles via action at a distance will involve time delays which depends on the state of the whole system. In Driver [63] and in Hoag and Driver [111], it is noted that if one considers that the basic laws of physics are symmetric with respect to time reversal, then the existence of these delays implies that there should also be advanced terms in the equations, and thus one is led to a system of functional differential equations with mixed arguments (Hoag and Driver [111]), and of neutral type (Driver [63]).

In summary and in conclusion, despite the fact that much of the work by Driver and his collaborators on electrodynamics was published nearly 40 years ago, many interesting questions related to the fundamental issues of electrodynamics remain unsolved mathematically and Driver's models remain as a source of inspiration for the theoretical development and a testing tool for new results.

2.2. *Position control*

State-dependent delays arise naturally in automatic position control if in the feedback loop running times of signals between the object of study and a reference point are taken into account.

In [205], the following simple and idealized situation is considered: An object moves along a line and regulates its position relative to an obstacle by means of signals which are reflected by the obstacle. Let $x(t)$ denote the position of the object at time $t \in \mathbb{R}$. The aim of control is that the object should not collide with the obstacle located at $-w < 0$, and that the object should be close to a preferred position at distance w from the obstacle, i.e., at $0 \in \mathbb{R}$. The difficulty for the control is that measurement of the position via signal running times takes time during which the object is moving. More precisely, assume that signals travel from the object to the obstacle at a speed $c > 0$ and are reflected. The object senses the reflected signals and measures the signal running time $s(t)$ between the emission and detection at time t:

$$cs = \left|x\bigl(t - s(t)\bigr) + w\right| + \left|x(t) + w\right|.$$

Then it uses s to compute a distance d from the obstacle according to

$$d = \frac{c}{2}s.$$

This seems to be reasonable since it gives the true distance at time t at least if at times $t - s(t)$ and t the object is in the same position. We must however emphasize that in general d is only a *computed* length and not the true distance, and that we consider a situation where there is no direct, immediate access to the true position.

Depending on the computed distance $d - w$ from the preferred the object adjusts its speed in size and direction, with a reaction time lag $r > 0$ which is assumed to be constant. This negative feedback mechanism is then described by the differential equation

$$x'(t) = v\bigl(d(t - r) - w\bigr)$$

where $v : \mathbb{R} \to \mathbb{R}$ represents negative feedback with respect to the preferred position $0 \in \mathbb{R}$ in the sense that

$$\delta v(\delta) < 0 \quad \text{for all } \delta \neq 0$$

holds. Therefore, we are led to the system

$$x'(t) = v\left(\frac{c}{2}s(t-r) - w\right), \tag{2.2.1}$$

$$cs(t) = \left|x\big(t - s(t)\big) + w\right| + \left|x(t) + w\right| \tag{2.2.2}$$

for positive parameters c, w, r and a negative feedback nonlinearity v. Notice that for motion $x : \mathbb{R} \to \mathbb{R}$ with speed $|x'|$ bounded by a constant $b < c$, that is, slower than the signal speed, the equation

$$s = \frac{1}{c}\big(\left|x(t-s) + w\right| + \left|x(t) + w\right|\big)$$

equivalent to (2.2.2) has a unique solution $s = \sigma(x|_{(-\infty,t]})$ because for given x and t the right-hand side of the equation defines a contraction $[0, \infty) \to [0, \infty)$. Then one can take the right-hand side of Eq. (2.2.2) with $t - r - \sigma(x|_{(-\infty,t-r]})$ and $t - r$ instead of $t - s$ and t, respectively, and replace $cs(t - r)$ in Eq. (2.2.1), which yields a single delay differential equation with state-dependent delay. Essentially the same reasoning shows that for Lipschitz continuous solutions $x : [-h, t_e) \to \mathbb{R}$, $h > 0$ and $t_e > 0$, which have Lipschitz constants strictly less than c and satisfy suitable boundedness conditions, the system (2.2.1)–(2.2.2) can be rewritten as a single delay differential equation of the form (1.0.1).

A closely related model, with an explicit expression for a fraction of the signal running time instead of Eq. (2.2.2) for the total signal running time, was mentioned earlier by Nussbaum [177]. A similar model was also proposed by Messer [161].

It is perhaps more realistic to replace the first order differential equation (2.2.1) with the constant reaction lag $r > 0$ by Newton's law

$$x'' = A$$

with an instantaneous restoring force A which depends on the computed distance d. Also friction might be taken into account. Such a model was studied in [208], by means of the fundamental theory presented in the next section.

We describe the main results from [205,208], namely existence of stable periodic orbits, in Section 7.3.

In [32,33] Büger and Martin study a case of velocity control which involves signal running times. They consider an object travelling along a line which, ideally, should have a certain prescribed constant velocity v_0 throughout its whole journey. The object regulates its velocity $v = x'$ by adjusting its acceleration $a = v'$ according to a negative feedback relation

$$a \cdot (v - v_0) < 0 \quad \text{for all } v \in \mathbb{R} \setminus \{v_0\},$$

that is, the object speeds up if $v < v_0$ and slows down when $v > v_0$. This strategy is remotely controlled by a base located at $x = 0$ to which the object transfers its current velocity v with a certain transmission velocity $c_1 > 0$, and the negative feedback information is then transmitted back from the base to the object with a transmission velocity $c > 0$. The total signal running time of the signals emitted from the object in the past and transmitted back from the base to the object as to arrive at time t is given by

$$s = s_1 + s_2$$

where

$$s_1 = \frac{1}{c_1}\bigl|x(t-s)\bigr| \quad \text{and} \quad s_2 = \frac{1}{c}\bigl|x(t)\bigr|.$$

If an additional constant reaction time $r > 0$ of the base is taken into account then the total transmission delay is

$$r + s(t)$$

where now

$$s(t) = \frac{1}{c_1}\bigl|x\bigl(t - r - s(t)\bigr)\bigr| + \frac{1}{c}\bigl|x(t)\bigr|.$$

The preceding equation and the second order differential equation

$$x''(t) = A\bigl(x'\bigl(t - r - s(t)\bigr) - v_0\bigr)$$

with a negative feedback nonlinearity $A : \mathbb{R} \to \mathbb{R}$ constitute the model. Büger and Martin investigated a simplification which neglects the running time of the signal from the object to the base, in which case the model is reduced to the single equation

$$x''(t) = A\left(x'\left(t - r - \frac{1}{c}\bigl|x(t)\bigr|\right) - v_0\right) \tag{2.2.3}$$

with an explicitly given state-dependent delay. It is shown in [32,33] that close to segments of constant velocity solutions $t \mapsto v_0 t + c$ there exist segments of solutions of Eq. (2.2.3) for which $t - r - \frac{1}{c}|x(t)|$ remains bounded from above by some T. In this case the object reacts only to velocities achieved before $t = T$, which may not be adequate for larger velocities reached later. The phenomenon occurs for solutions whose speed $|v| = |x'|$ approaches the signal speed c or grows beyond. Büger and Martin call it the *escaping disaster*. In [33] they design another control mechanism which overcomes this kind of instability of the constant velocity solutions.

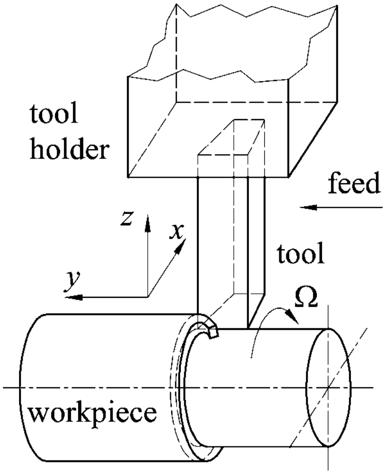

Fig. 1. A cutting process.

2.3. *Mechanical models*

State-dependent models have been proposed and investigated in mechanics, as well. Johnson [123] studied a steel rolling mill control system in 1972 where state-dependent delays have already been encountered. Nevertheless, state-dependent delay models have not frequently used in mechanics, since the required mathematical methods, like linearization techniques, were only recently developed (see Sections 3.4 and 3.6).

Insperger, Stépán and Turi [117] proposed a two degree of freedom model for turning process. This models a machine tool where a workpiece is rotating, the tool cuts the surface that was formed in the previous cut, see Fig. 1. The chip thickness is determined by the current and a previous position of the tool and the workpiece. In standard models the time delay between two succeeding cuts is considered to be equal to the period of the workpiece rotation. More realistic models given in the machine tool literature include the feed motion and the consequent trochoidal path of the cutter tooth. In this case the time delay between the succeeding cuts is not constant, it changes periodically in time. Time periodic delays also arise in the model of varying spindle speed machining. If the regeneration process is modeled more accurately, then the vibration of the tool is also included in the model, and this results a model with state-dependent delay. The system can be modeled as a two degree of freedom oscillator that is excited by the cutting force, so the governing equations are

$$m\ddot{x}(t) + c_x\dot{x}(t) + k_x x(t) = F_x, \tag{2.3.1}$$

$$m\ddot{y}(t) + c_y\dot{y}(t) + k_y y(t) = -F_y, \tag{2.3.2}$$

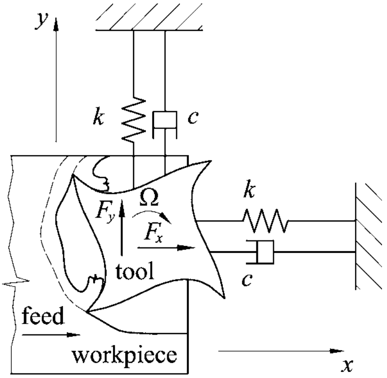

Fig. 2. A milling process.

where the associated model parameters are mass m, damping c_x, c_y and stiffness k_x, k_y. The x and y components of the cutting force are, respectively,

$$F_x = K_x w h^q, \quad F_y = K_y w h^q,$$

where K_x and K_y are the cutting coefficients in the x and y components, w is the depth of cut, h is the chip thickness, and the exponent $0 < q < 1$ is constant. The time delay between the present and the previous cuts is determined by the equation

$$R\Omega\tau(x_t) = 2R\pi + x(t) - x\bigl(t - \tau(x_t)\bigr), \tag{2.3.3}$$

where Ω is the spindle speed given in [rad/s] and R is the radius of the workpiece. This is an implicit equation for the time delay, and τ depends on the solution, as well. The chip thickness satisfies

$$h = v\tau(x_t) + y(t) - y\bigl(t - \tau(x_t)\bigr),$$

where v is the feed speed. Therefore the model equations are

$$m\ddot{x}(t) + c_x\dot{x}(t) + k_x x(t) = K_x w\bigl(v\tau(x_t) + y(t) - y\bigl(t - \tau(x_t)\bigr)\bigr)^q,$$

$$m\ddot{y}(t) + c_y\dot{y}(t) + k_y y(t) = -K_y w\bigl(v\tau(x_t) + y(t) - y\bigl(t - \tau(x_t)\bigr)\bigr)^q,$$

where the delay function is defined by (2.3.3). In [117] the linearized stability of an equilibrium solution was also studied using the method of [101] and [108]. It was shown that the linearized equation is almost equal to the standard constant delay machine tool vibration equation, the difference is a term with a small coefficient.

A related problem was studied in [116], where a two degree freedom model of milling process is considered. In this machine a tool with equally spaced teeth rotating with constant spindle speed, and cuts the surface that was formed in the previous cut, see Fig. 2. In this case the system again can be described by (2.3.1)–(2.3.2), but now the damping and stiffness parameters are equal in both x and y directions: $c_x = c_y = c$, $k_x = k_y = k$, and it was shown that the model equations have the form

$$m\ddot{x}(t) + c\dot{x}(t) + kx(t) = \sum_{j=1}^{N} \alpha_{x,j}(t)\Big(R\big(1 - \cos(\Omega\tau_j - \vartheta)\big) + \big(v\tau_j + x(t-\tau_j) - x(t)\big)\sin\varphi_j(t) + \big(y(t-\tau_j) - y(t)\big)\cos\varphi_j(t)\Big)^q, \tag{2.3.4}$$

$$m\ddot{y}(t) + c\dot{y}(t) + ky(t) = \sum_{j=1}^{N} \alpha_{y,j}(t)\Big(R\big(1 - \cos(\Omega\tau_j - \vartheta)\big) + \big(v\tau_j + x(t-\tau_j) - x(t)\big)\sin\varphi_j(t) + \big(y(t-\tau_j) - y(t)\big)\cos\varphi_j(t)\Big)^q. \tag{2.3.5}$$

Here N is the number of teeth,

$$\alpha_{x,j}(t) = wg\big(\varphi_j(t)\big)\big(K_t\cos\big(\varphi_j(t)\big) + K_n\sin\big(\varphi_j(t)\big)\big),$$
$$\alpha_{y,j}(t) = wg\big(\varphi_j(t)\big)\big(K_n\cos\big(\varphi_j(t)\big) - K_t\sin\big(\varphi_j(t)\big)\big),$$

K_t and K_n are tangential and normal cutting coefficients, g is a screen function, it is equal to 1 if the jth tooth is active, and it is 0 if not, $\phi_j(t) = -\Omega t + (j-1)\vartheta$, Ω is the spindle speed, $\vartheta = 2\pi/N$ is the pitch angle, and the time delays $\tau_j = \tau_j(t, x_t, y_t)$ are defined by the implicit relations

$$\begin{aligned}&\big(v\tau_j + x(t-\tau_j) - x(t)\big)\cos\phi_j(t) - \big(y(t-\tau_j) - y(t)\big)\sin\phi_j(t)\\ &\quad = R\sin(\Omega\tau_j - \vartheta)\end{aligned} \tag{2.3.6}$$

for $j = 1, \ldots, N$. It is easy to check that the functions on the right-hand sides of (2.3.4) and (2.3.5) are periodic in time with period $\bar{\tau} = 2\pi/(N\Omega)$, and the time delay functions τ_j are periodic in time with period $T = N\bar{\tau}$. Moreover, $\tau_j(t + \bar{\tau}, x_t, y_t) = \tau_{j-1}(t, x_t, y_t)$ gives the connection between time delays associated to two succeeding cuts. Note that if the vibration of the tool is not included in the delay model, i.e., $x(t) = 0$ and $y(t) = 0$, then Eq. (2.3.6) is simplified to

$$v\tau_j\cos\phi_j(t) = R\sin(\Omega\tau_j - \vartheta),$$

which yields that the delay depends only on time. This case of time periodic delay was investigated earlier in the literature. If the feed is negligible relatively to the diameter, i.e., $v\tau_j \ll R$, then if we substitute $v\tau_j = 0$ into the previous equation we get $\sin(\Omega\tau_j - \vartheta) = 0$.

This gives the constant delays $\tau_j = \bar{\tau} = \vartheta/\Omega$ that was usually used in standard milling models. Linearized stability of model (2.3.4)–(2.3.5) was also studied in [116] using the results of [101] and was compared to the stability of the standard time-periodic time delay models.

2.4. *Delay adaptation in neural networks and distributed systems*

A synaptic connection between two neurons is referred as to a delay line if the signal transmission is delayed. In neural circuits, time delays arise because interneural distances and axonal conduction times are finite [5,141–143,147,163,219]. In several sensory systems, delay lines are essential for coordinating activities. Examples include the auditory system of barn owls, echo location in bats, and the lateral line system of weakly electric fish. See [41] and the survey article [40]. Delay lines are also important for managing distributed systems, for such systems a fundamental problem concerns how the flow of information from distinct, independent components can be best regulated to optimize a prescribed performance of the network. For example, in parallel computing machines the asynchronous output of independent processors must be integrated to yield well-defined results.

Several possible biophysical mechanisms can be envisioned by which adjustable delays could be achieved, and recent development in the physiology of synapses and dendrites suggests that not only synaptic weights, but also synaptic delays vary [1,215] and changing synaptic delays have significant impact on the neural signal processing.

Time delays have important influence on learning algorithms. As noted in [19], not only delays affect the learning of other parameters such as gains, time constants or synaptic weights but also *delays themselves may be part of the adjustable parameters of a neural system so as to increase the range of its dynamics*. There exist numerous examples of finely tuned delays and delay lines, and *certainly many delays are subject to variations, for instance during the growth of an organism.*

Much of the existing work related to delay adaptation in neural networks have been concentrating on the fine tuning of a selected set of parameters in architectures already endowed of a certain degree of structure. In these applications, the delays are arranged in orderly arrays of delay lines, these delay lines are essentially part of a feedforward network for which the learning task is much more simple and the delays adjust on a slow time scale. In [199], the successive parts of a spoken word are delayed differentially in order to arrive simultaneously onto a unit assigned to the recognition of that particular word. Baldi and Atiya [19] viewed this as a "time warping" technique for optimal matching in the sense that for a given input $I(t)$, the output of the ith delay line is given by the convolution

$$O_i(t) = \int_0^\infty K(i,s) I(t-s)\,\mathrm{d}s,$$

where $K(i,s)$ is a Gaussian delay kernel

$$K(i,s) = \frac{1}{\sqrt{2\pi}\sigma} \mathrm{e}^{-(s-iT)^2/(2\sigma^2)}$$

and T is a parameter used to discretize the possible delays. In this application, the adjustment of delays on a slow time scale may take place across several speakers during the basic development of a speech recognizer and thus the adjustment is independent of the dynamics of the network. However, it is also desirable that delays adjust on a fast scale to adapt in real time to one particular speaker during normal functioning. The above work of Baldi and Atiya, as well as those in [51,166], develops models for delay adaptation with the help of a global teacher signal. It is shown in [51] that a network with adaptable delays can achieve smaller errors than a network with fixed delays, if they both have the same number of neurons and connections. Other rules and algorithms have been developed by which excitatory postsynaptic potentials from different synapses can be gradually pulled into coincidence, see, for example, [113].

Examples of self-organized delay adaptation can be found in [73]. For example, time delays in the optic nerve are equalized [192], signals in visual callosal axons arrive simultaneously at all axonal endings [115], and neurons in vitro can inhibit the formation of a myelin sheet by firing at a low frequency [193].

Two different mechanisms, delay shift and delay selection, are investigated in [73,74] for the self-organized adaptation of transmission delays in the nervous system.

To formulate the model for a network consisting of a large number of presynaptic neurons and one postsynaptic neuron which receives its input lines, we consider the idealized situation where there is a continuous set of input connections described by two functions, $\rho(\tau,t)$ and $\omega(\tau,t)$, for the delays and weights, respectively: $\rho(\tau,t)\,\mathrm{d}\tau$ gives the fraction of connections with delays in $[\tau,\tau+\mathrm{d}\tau]$, and $\omega(\tau,t)$ is the average weight of connections with delay τ. We assume that delays in the system adapt on a developmental time scale, and thus the model formulated below does not involve the internal dynamics of the network. In the continuous description, the input density $J(\tau,t)$ provided by the synapses at delay τ after presentation of a pattern has the simple form

$$J(\tau,t)=\rho(\tau,t)\omega(\tau,t).$$

The dynamics of the input are governed by two simultaneous equations: a balance equation for the input density

$$\frac{\partial}{\partial t}J(\tau,t)=-\frac{\partial}{\partial\tau}\bigl[J(\tau,t)v(\tau,t)\bigr]+Q(\tau,t),\tag{2.4.1}$$

and a continuity equation for $\rho(\tau,t)$, indicating the conservation of the number of neural connections

$$\frac{\partial}{\partial}\rho(\tau,t)=-\frac{\partial}{\partial\tau}\bigl[\rho(\tau,t)v(\tau,t)\bigr].\tag{2.4.2}$$

The drift velocity, $v(\tau,t)$, and the source term, $Q(\tau,t)$, are defined according to the Hebbian principles. In particular, in the case of delay shifts, the weights are not modified and the source term vanishes. Therefore, the dynamics is completely governed by (2.4.2) where the velocity, $v = \mathrm{d}\tau/\mathrm{d}t$, of the delays realizes the Hebbian adaptation

$$v(\tau, t) = \gamma_\tau \int_{-\infty}^{+\infty} W_\tau(\tau - s) P(s, t)\, \mathrm{d}s, \tag{2.4.3}$$

and γ_τ denotes the learning rate, $W_\tau(x)$ denotes a learning window for delay adaptation. $W_\tau(x)$ should be positive when the presynaptic contribution precedes the postsynaptic spike, and negative in the other case, and this rule will adjust the delays such that their effects will align in time at the soma [72]. The distribution of spike times, $P(s, t)$, of a neuron depends on the input and its statistics, and this is assumed to be of the form $P(s, t) = \beta J(s, t)$ in the work of [73,74] and it is justified if the input is sufficiently high and if there is some random background activity. Note that delay shift mechanism assumes that the transmission delays themselves are altered. This mechanism is possible because transmission velocities in the nervous system can be altered, for example, by changing the length and thickness of dendrites and axons, the extent of myelination of axons, or the density and type of ion channels. See [74,75].

In the case of delay selection, the drift velocity of the delays vanishes and the total input of the postsynaptic neuron is not conserved. Equations (2.4.1) and (2.4.2) result in

$$\rho(\tau, t) \frac{\partial}{\partial t} \omega(\tau, t) = Q(\tau, t). \tag{2.4.4}$$

Again, the source term is derived from the Hebbian rule by

$$Q(\tau, t) = \gamma_\omega \omega(\tau, t) \rho(\tau, t) \int_{-\infty}^{+\infty} W_\omega(\tau - s) P(s, t)\, \mathrm{d}s,$$

with γ_ω denoting the corresponding learning rate, and W_ω representing a learning window that is maximal just before the time of spiking—leading to a selection of delay lines for which the effects align at soma.

In the aforementioned delay-adaptation models, it is assumed that delays in the system adapt on a developmental time scale, and thus the temporal development of ρ and ω is determined by an average over an ensemble of presynaptic input patterns. In the recent work [114], the self-organized adaptation of transmission delays is incorporated into the projective adaptive resonance theory developed in [38,39], and this self-organized adaptation of delay is driven by the dissimilarity between input patterns and stored patterns in a neural network designed for pattern recognition from data sets in high dimensional spaces. This adaptation can be regarded as a consequence of the Hebbian learning law, and the dynamic adaptation can be modeled by a nonlinear differential equation and hence a system of delay differential equations with adaptive delay is used.

We now describe the model for such a network that consists of two layers of neurons. Denote the nodes in F_1 layer (Comparison/Input Processing layer) by P_i, $i \in \Lambda_p := \{1, \ldots, m\}$; nodes in F_2 layer (Clustering layer) by C_j, $j \in \Lambda_c := \{m+1, \ldots, m+n\}$; the activation of F_1 node P_i by x_i, the activation of F_2 node C_j by y_j; the bottom-up weight from P_i to C_j by z_{ij}, the top-down weight from C_j to P_i by w_{ji}.

The STM (short-term memory) equations for neurons in F_1 layer are given by

$$\epsilon_p \frac{\mathrm{d}x_i(t)}{\mathrm{d}t} = -x_i(t) + I_i, \quad t \geqslant -1,\ i \in \Lambda_p, \tag{2.4.5}$$

where $0 < \epsilon_p \ll 1$, I_i is the constant input imposed on P_i.

The change of the STM for a F_2 neuron depends on the internal decay, the excitation from self-feedback, the inhibition from other F_2 neurons and the excitation by the bottom-up filter inputs from F_1 neurons. Namely, we have the STM equations for the committed neurons in F_2 layer:

$$\begin{aligned}\epsilon_c \frac{\mathrm{d}y_j(t)}{\mathrm{d}t} &= -y_j(t) + \bigl[1 - Ay_j(t)\bigr]\bigl[f_c\bigl(y_j(t)\bigr) + T_j(t)\bigr] \\ &\quad - \bigl[B + Cy_j(t)\bigr] \sum_{k \in \Lambda_c \setminus \{j\}} f_c\bigl(y_k(t)\bigr), \quad t \geqslant 0,\ j \in \Lambda_c,\end{aligned} \tag{2.4.6}$$

where $0 < \epsilon_c \ll 1$, $f_c : \mathbb{R} \to \mathbb{R}$ is a signal function, A, B, and C are non-negative constants, and the bottom-up filter input T_j is given by

$$T_j(t) = D \sum_{i \in \Lambda_p} z_{ij}(t) f_p\bigl(x_i\bigl(t - \tau_{ij}(t)\bigr)\bigr)\mathrm{e}^{-\alpha\tau_{ij}(t)}, \quad t \geqslant 0, \tag{2.4.7}$$

where D is a scaling constant, $f_p : \mathbb{R} \to \mathbb{R}$ is the signal function of the input layer. It is assumed here that the signal transmissions between two layers are not instantaneous and the signal decays exponentially at a rate $\alpha > 0$. This assumption that signal strength decays if the transmission is delayed can be replaced by the mechanism of *delay selection* by replacing (2.4.7) by

$$\begin{aligned}T_j(t) = D_f &\sum_{i \in \Lambda_p, \tau_{ij}(t)=0} z_{ij}(t) f_p\bigl(x_i(t)\bigr) \\ &+ D_d \sum_{i \in \Lambda_p, \tau_{ij}(t)>0} z_{ij}(t) f_p\bigl(x_i\bigl(t - \tau_{ij}(t)\bigr)\bigr)\end{aligned}$$

with two different weight factors $0 < D_d \ll D_f$.

The term τ_{ij} is the signal transmission delay between the cluster neuron C_j and the input neuron P_i. It is assumed that this delay is driven by the dissimilarity in the sense that the signal processing from the input neuron P_i to the cluster neuron C_j is faster when the output from P_i is similar to the corresponding component of w_{ji} of the feature vector $w_j = (w_{ji})_{i \in \Lambda_p}$ of the cluster neuron C_j. Therefore, we have

$$\beta \frac{\mathrm{d}\tau_{ij}(t)}{\mathrm{d}t} = -\tau_{ij}(t) + E\bigl[1 - h_{ij}(t)\bigr], \quad t \geqslant 0,\ i \in \Lambda_p,\ j \in \Lambda_c, \tag{2.4.8}$$

where $\beta > 0$, $E \in (0, 1)$ are constants and

$$h_{ij}(t) = S\bigl(d\bigl(f_p\bigl(x_i(t), w_{ji}(t)\bigr)\bigr), z_{ij}(t)\bigr)$$

is the similarity measure between the output signal $f_p(x_i(t))$ and the corresponding component $w_{ji}(t)$ of the feature vector of the cluster neuron C_j, with respect to the significance factor of the bottom-up synaptic weight $z_{ij}(t)$, here d is the usual absolute value function and $S:\mathbb{R}^+ \times [0,1] \to [0,1]$ is a given function, non-increasing with respect to the first argument and nondecreasing with respect to the second argument. Moreover, $S(0,1) = 1$ (the similarity measure is 1 with complete similarity and maximal synaptic bottom-up weight) and $S(+\infty, z) = S(x, 0) = 0$ for all $z \in [0,1]$ and $x \in \mathbb{R}^+$ (the similarity measure is 0 with complete dissimilarity or minimal bottom-up synaptic weight). Therefore, if $\tau_{ij}(0) = 0$ then from (2.4.8) it follows that $0 \leqslant \tau_{ij}(t) \leqslant E$ for all $t \in \mathbb{R}^+$, and moreover, if $h_{ij}(t) = 1$ on an interval $[0, b)$ for a given $b > 0$ then $\tau_{ij}(t) = 0$ for all $t \in [0, b)$.

The equation governing the change of the weights follows from the usual synaptic conservation rule and only connections to activated neurons are modified. The top-down weights are modified so that the template will point to the direction of the delayed and exponentially decayed outputs from F_1 layer. Therefore, we have

$$\gamma \frac{\mathrm{d}w_{ji}(t)}{\mathrm{d}t} = f_c\big(y_j(t)\big)\big[-w_{ji}(t) + f_p\big(x_i\big(t - \tau_{ij}(t)\big)\mathrm{e}^{-\alpha\tau_{ij}(t)}\big)\big] \tag{2.4.9}$$

for $t \geqslant 0$, $i \in \Lambda_p$, $j \in \Lambda_c$, where $\gamma > 0$ is a given constant.

The bottom-up weights are changed according to the competitive learning law and Weber law that says that LTM size should vary inversely with input pattern scale. Thus the LTM equations for committed neurons C_j in F_2 layer are

$$\begin{aligned}\delta \frac{\mathrm{d}z_{ij}(t)}{\mathrm{d}t} = f_c\big(y_j(t)\big)\Big[&\big(1 - z_{ij}(t)\big)h_{ij}(t)L - z_{ij}(t)\big(1 - h_{ij}(t)\big) \\ &- z_{ij}(t) \sum_{k \in \Lambda_p \setminus \{i\}} h_{kj}(t)\Big], \quad t \geqslant 0,\ i \in \Lambda_p,\ j \in \Lambda_c,\end{aligned} \tag{2.4.10}$$

where $0 < \delta \ll \gamma = \mathrm{O}(1)$ and $L > 0$ is a given constant.

Equations (2.4.5)–(2.4.10) give a system of functional differential equations where the dynamics of the delay $\tau_{ij}(t)$ is adaptive and is described by the nonlinear equation (2.4.8). The dynamics is investigated in [114] in the case where the signal functions f_p and f_c are step functions, though much remains to be done in the general case.

2.5. *Disease transmission and threshold phenomena*

Delay differential equations with state-dependent delay arise naturally from the modeling of infection disease transmission, the modeling of immune response systems and the modeling of respiration, where the delay is due to the time required to accumulate an appropriate dosage of infection or antigen concentration.

Following [201], we consider a particular infectious disease in an isolated population that is divided into several disjoint classes (compartments) of individuals: the susceptible class (those individuals who are not infective but are capable of contracting the disease and become infective), the exposed class (those who are exposed but not yet infective), and the infective class (those individuals who are capable of transmitting the disease to others), and the removed class (those who have had the disease and are dead, or have recovered and are permanently immune, or are isolated until recovery and permanent immunity occur). Let $S(t)$, $E(t)$, $I(t)$ and $R(t)$ be the size of each class at time t, and assume the following:

(i) the rate of exposure of susceptibles to infectives at time t is given by $-rS(t)I(t)$;

(ii) an individual who becomes infective at time t recovers from the infection (is thus removed from the population) at time $t+\sigma$, where σ is a positive constant;

(iii) an individual who is first exposed at time τ becomes infective at time t if

$$\int_{\tau}^{t} \bigl[\rho_1(x)+\rho_2(x)I(x)\bigr]\,\mathrm{d}x = m,$$

where ρ_1, ρ_2 are nonnegative functions and m is a given positive constant;

(iv) the population size remains to be a constant N.

The motivation for assumption (iii), the basis for a threshold model, is that human body can often control a small exposure to an infection, that is, there is a tolerance level below which the body's immune system can combat exposure to infection. When too large an exposure results, the individual contracts the disease. The amount of exposure received depends on the duration of the exposure and the amount of infectivity around the individual, that is assumed to be proportional to the number of infective individuals in the population. Thus, during the time interval $[t, t+h]$ an exposure of $\int_t^{t+h} \rho_2(x)I(x)\,\mathrm{d}x$ is accumulated where ρ_2 is a proportionality function which is a measure of the amount of infection communicated per infective (virulence). When the total exposure reaches the threshold m, the individual moves from class (E) to class (I). The term ρ_1 is the rate of accumulation of exposure independent of the number of infectives (such as constant input of virus from the external environment). In what follows, we consider the simple case where $\rho_1 = 0$, $\rho_2 = \rho$.

We assume the initial distribution of the infectives is given by a monotone function $I_0 : [-\sigma, 0] \to [0, \infty)$ such that $I_0(-\sigma) = 0$, and $I_0(0) > 0$ infective individuals are inserted in the population at $t = 0$. It is convenient to extend I_0 to the whole real line

$$I_0^{\mathrm{e}}(t) = \begin{cases} 0, & |t| > \sigma; \\ I_0(t), & -\sigma < t \leqslant 0; \\ I_0(0) - I_0(t-\sigma), & 0 \leqslant t \leqslant \sigma, \end{cases}$$

so that the extension $I_0^{\mathrm{e}}(t)$ describes the number of initial infectives who are still present as infectives at time $t \in [-\sigma, \infty)$.

From (i) and (ii), it follows that the number of new infectives introduced into the population at time t is given by $-\int_{t-\sigma}^{t} \frac{\mathrm{d}}{\mathrm{d}x} S(\tau(x))H(x)\,\mathrm{d}x$, where $H(x) = 0, x < 0$ and $H(x) = 1$, $x > 0$. Therefore,

$$I(t) = I_0^{\mathrm{e}}(t) - \int_{t-\sigma}^{t} \frac{\mathrm{d}}{\mathrm{d}x} S\bigl(\tau(x)\bigr)H(x)\,\mathrm{d}x, \quad t \geqslant 0.$$

For the infection to spread, some of the initial susceptible population must become infective before time σ. Thus, we assume there is $t_0 < \sigma$ so that the following "admissibility" condition,

$$\int_0^{t_0} \rho(x) I_0^{\mathrm{e}}(x)\,\mathrm{d}s = m,$$

must be met.

Then the model equations become

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} S(t) = -rS(t)I(t), \\ I(t) = I_0^{\mathrm{e}}(t) - \displaystyle\int_{t-\sigma}^{t} \frac{\mathrm{d}}{\mathrm{d}x} S\big(\tau(x)\big) H(x)\,\mathrm{d}x, \\ E(t) = S\big(\tau(t)\big) - S(t), \\ R(t) = N - S(t) - I(t) - E(t), \\ \displaystyle\int_{\tau(t)}^{t} \rho(x) I(x)\,\mathrm{d}x = m. \end{cases}$$

If we further adopt the convention that $\tau(t) = 0$ for $t \leqslant t_0$, then we obtain a state-dependent delay differential equation for $S(t)$:

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} S(t) = -rS(t)I(t), \\ I(t) = I_0(t) + S\big(\tau(t-\sigma)\big) - S\big(\tau(t)\big), \\ \displaystyle\int_{\tau(t)}^{t} \rho(x) I(x)\,\mathrm{d}x = m, \quad t > t_0, \\ \tau(t) = 0, \quad t \leqslant t_0. \end{cases}$$

Other related models involving threshold conditions that determine the state-dependence of delay can be found in Gatica and Waltman [87–89], Hoppensteadt and Waltman [112], Smith [189], and Waltman [201]. Relatively complete references can be found in the work of Kuang and Smith [136,137], where the prototype equation takes the form

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} x(t) = -\nu x(t) - \mathrm{e}^{-\eta\tau} f\big(x(t-\tau)\big), \\ \displaystyle\int_{t-\tau}^{t} k\big(x(t), x(s)\big)\,\mathrm{d}s = m, \end{cases} \tag{2.5.1}$$

with nonnegative constants ν, η and m, and a positive function k, as well as a nonlinearity $f : \mathbb{R} \to \mathbb{R}$. Again, in the contents of epidemiological modeling, $x(t)$ may represent the proportion of a population which is infective at time t and the second equation in system (2.5.1) may reflect that an individual who is first exposed to the disease at time $t - \tau$ becomes infectious at time t if, during the interval from $t - \tau$ to t, a threshold level of exposure is accumulated where per unit time exposure depends on the infective fraction $x(s)$ via $k(x(t), x(s))$.

2.6. *Population models and size-dependent interaction*

Recent efforts in modeling state-dependent phenomena in population dynamics involve structured models, and state-dependent delay normally arises from a certain threshold condition. For example, in the work [170], Nisbet and Gurney considered insect populations which have several life stages (instars). After constructing a mathematical model consisting of an equation for the mass density function of the population, and under the homogeneity assumption for the population at each life stage, they reduced the model to a system of delay differential equations for the size of the population in each life stage. The threshold delays then appear due to the assumption that the insect must spend an amount of time in the larval stage sufficient to accumulate a threshold amount of food. See also [3].

This idea was adopted in the work of Arino, Hbid and Bravo de la Parra [8] for the growth of a population of fish where they introduce an additional stage between the eggs and the mobile larvae, the so-called (S1) larval stage. The state variable for this stage is $n_1(a,t)$, and the passage through (S1) is described with the help of another variable $q_1(a,t)$, the amount of food eaten up to time t by an individual entered in (S1) a units of time earlier. The introduction of this variable makes it possible to formulate the condition for any individual to have eaten a certain amount of food Q_1 (threshold) during the whole duration (bounded above by T_1) an individual can spend in (S1). The variation of ingested food is governed by the standard structured model (see [162]) subject to zero boundary and initial conditions that can be solved by integration along the characteristics to give

$$q_1(a,t) = \int_{t-a}^{t} \frac{K_1}{N_1(\sigma)+C_1}\,\mathrm{d}\sigma, \qquad t > a,$$

where K_1 is the quantity of food flowing into the species habitat per unit of volume, per unit of time, C_1 is the food(converted into a number of individuals) taken per unit of volume by consumers other than (S1) stage, and $N_1(t) = \int_0^{T_1} n_1(a,t)\,\mathrm{d}a$ is the population in stage (S1) which is susceptible to enter the next stage at time t per unit of volume. Hence an individual moves out of the (S1) stage exactly at time t if it entered in the (S1) stage $a_1(t)$ units of time earlier, where $a_1(t)$ is given by the threshold condition

$$\int_{t-a_1(t)}^{t} \frac{K_1}{N_1(\sigma)+C_1}\,\mathrm{d}\sigma = Q_1,$$

from which it follows that

$$\frac{\mathrm{d}}{\mathrm{d}t}a_1(t) = -\frac{N_1(t-a_1(t)) - N_1(t)}{N_1(t)+C_1}. \tag{2.6.1}$$

The introduction of $a_1(t)$ through the above threshold condition ties the change of individual states to the dynamics of the population at the population level. From the definition of $a_1(t)$, one naturally has $n_1(a,t) = 0$ for all $a > a_1(t)$. The dynamics for $n_1(a,t)$ with $0 < a < a_1(t)$ is given by

$$\begin{cases} \dfrac{\partial}{\partial a} n_1(a,t) + \dfrac{\partial}{\partial t} n_1(a,t) = -f(a) n_1(a,t), \quad 0 < a < a_1(t),\ t > 0, \\ n_1(a,0) = 0, \qquad n_1(0,t) = B(t), \end{cases}$$

where the function f is related to the individual resistance to fluctuation of food capacities, and $B(t)$ is the density of eggs laid per unit of volume at time t. In the special case where the eggs of a given year are determined directly in terms of passive larvae that survived some years earlier, we have

$$B(t) = kN_1(t-r)$$

for some positive constants r and k. This yields

$$\begin{cases} N_1(t) = k \displaystyle\int_{t-a_1(t)}^{t} \exp\left(-\int_0^{t-a} f(\sigma)\,\mathrm{d}\sigma\right) N_1(a-r)\,\mathrm{d}a, \\ \displaystyle\int_{t-a_1(t)}^{t} \frac{K_1}{N_1(\sigma)+C_1}\,\mathrm{d}\sigma = Q_1, \end{cases} \tag{2.6.2}$$

or, equivalently,

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} N_1(t) = kN_1(t-r) - \big(1 - a_1'(t)\big) \exp\left(-\displaystyle\int_0^{a_1(t)} f(\sigma)\,\mathrm{d}\sigma\right) kN_1(t-r) \\ \qquad\qquad - k \displaystyle\int_{t-a_1(t)}^{t} f(t-a) \exp\left(-\int_0^{t-a} f(\sigma)\,\mathrm{d}\sigma\right) N_1(t-a)\,\mathrm{d}a, \\ \displaystyle\int_{t-a_1(t)}^{t} \frac{K_1}{N_1(\sigma)+C_1}\,\mathrm{d}\sigma = Q_1. \end{cases} \tag{2.6.3}$$

Note that in the above system of FDEs, there are two components of the delay: a constant delay r and a state-dependent delay.

As the second equation can be written as (2.6.1) by differentiation, it is natural that Arino, Hadeler and Hbid [7] and Magal and Arino [148] considered the system with adaptive delays

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} x(t) = -f\big(x\big(t-\tau(t)\big)\big), \\ \dfrac{\mathrm{d}}{\mathrm{d}t} \tau(t) = h\big(x(t), \tau(t)\big). \end{cases}$$

The existence of periodic solutions for the above system with adaptive delays is considered, and their results will be described in Section 7.2.

In the context of population dynamics, the delay arises frequently as the maturation time from birth to adulthood and this time is in some cases a function of the total population [11]. In [52], the consequence of size-dependent competition among the individuals is investigated by using a system of delay differential equations with state-dependent delays for a population consisting of only two distinct size classes, juveniles and adults, under the assumption that individuals are born at a size $s = s_b$ and remain juvenile as long as $s < s_m$, and individuals mature on reaching the maturation size threshold $s = s_m$. Therefore, if the density of juvenile and adult individuals at time t are denoted by $J(t)$ and $A(t)$, respectively, and if juveniles and adults feed on a shared resource, denoted by $F(t)$, then

$$s_m - s_b = \int_{t-\tau(t)}^{t} \epsilon_g a F(x)\,\mathrm{d}x, \tag{2.6.4}$$

where it is assumed that juvenile individuals feed at a rate aF and use all ingested food for growth in size with conversion efficiency ϵ_g, and $\tau(t)$ is the juvenile delay at time t. Assuming further that adult individuals feed at a rate qaF and use all ingested food for reproduction with conversion efficiency ϵ_b (here q is the ratio between the adult and juvenile feeding rate), and that the (instantaneous) mortality is inversely proportional to food intake with proportionality constant μ, de Roos and Persson obtain the following set of equations for the dynamics of $(J(t), A(t), F(t))$:

$$\begin{cases} \dfrac{\mathrm{d}F(t)}{\mathrm{d}t} = D - aFA - qaFA, \\ \dfrac{\mathrm{d}J(t)}{\mathrm{d}t} = R(t) - R\bigl(t-\tau(t)\bigr)P(t)\dfrac{F(t)}{F(t-\tau(t)))} - \dfrac{\mu}{aF(t)}J(t), \\ \dfrac{\mathrm{d}A(t)}{\mathrm{d}t} = R\bigl(t-\tau(t)\bigr)P(t)\dfrac{F(t)}{F(t-\tau(t))} - \dfrac{\mu}{qaF(t)}A(t), \end{cases} \tag{2.6.5}$$

where

$$R(t) = \epsilon_b qaF(t)A(t)$$

is the total population birth rate at time t and

$$P(t) = \exp\left(-\int_{t-\tau(t)}^{t} \frac{\mu}{aF(x)}\,\mathrm{d}x\right)$$

denotes the probability that an individual which should mature at time t has survived its juvenile period. The ratio $F(t)/F(t-\tau(t))$ counts for the change in maturation rate due to a change in the juvenile delay $\tau(t)$, and this can be derived by considering the model formulation in terms of a hyperbolic partial differential equation for the size distribution of the consumer population $n(t, s)$. The corresponding boundary conditions reflect the fact that the flow rate at time t across the boundary of the size domain $s = s_b$ into the juvenile class equals to total population birth rate $R(t)$ at that time, and that the flow rate at time t across the boundary $s = s_m$ into the adult class equals $\epsilon_g aF(t)n(t, s_m)$.

Note that differentiation of (2.6.4) then yields an equation to govern the evolution of the delay

$$\frac{\mathrm{d}\tau}{\mathrm{d}t} = 1 - \frac{F(t)}{F(t-\tau)}.$$

Similarly, in [23], it is showed that size dependent birth processes where the lifespan of individuals is a function of the current population size lead to a certain integral equation,

$$x(t) = \int_{t-L(x(t))}^{t} b\big(x(s)\big)\,\mathrm{d}s, \tag{2.6.6}$$

differentiation then leads to the delay differential equation

$$\frac{\mathrm{d}}{\mathrm{d}t}x(t) = \frac{b(x(t)) - b(x(t-L(x(t))))}{1 - L'(x(t))b(x(t-L(x(t))))}. \tag{2.6.7}$$

One should emphasize that, despite a close correspondence between solutions of (2.6.6) and (2.6.7), caution must be employed in using one equation to investigate the other. For example, any constant is a solution of (2.6.7), whereas equation (2.6.6) only admits constant solutions whose values satisfy $x = b(x)L(x)$.

We note that early development of state-dependent delay models in economics and population biology was motivated by phenomenological considerations. For example, in [25, 146] the dynamics of price adjustment in a single commodity market that involves time delays due to production lags and storage policies is considered. The importance of the incorporation of a variable production delay is pointed out as certain commodities, once produced, may be stored for a variable period of time until market prices are deemed advantageous by the producer. In the field of population dynamics, motivated by the observation in Gambell [85] that for antarctic whale and seal populations, the length of time to maturity is a function of the amount of food (mostly krill) available, Aiello, Freedman and Wu [2] propose a stage-structured model of population growth, where the time to maturity is itself state dependent and the special form is suggested by the work [6] that describes how the duration of larval development of flies is a nonlinear increasing function of larval density. This model is further analyzed in [224]. An alternative version, which is designed to address the drawback in the Aiello–Freedman–Wu model that the maturation time for any newborn depends on the existing population size at the same time, is proposed in [76] based on the assumption that the maturation time depends on the size of the population which existed at the time of birth. In particular, if $r(t)$ is the date of birth of individuals who become mature at time $t \geqslant 0$, then the age length up to maturity at time t will be given by the function $\tau(z(r(t)))$. Consequently, $r(t)$ can be solved implicitly by

$$r(t) = t - \tau\big(z\big(r(t)\big)\big), \quad t \geqslant 0.$$

This modification in defining the density-delay dependent term results in the following system for the population with two stages: immature and mature, whose densities are denoted by $z(t) - x_m(t)$ and $x_m(t)$:

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t} z(t) = -\gamma z(t) + (\alpha + \gamma) x_m(t) - f\big(x_m(t)\big) x_m(t), \\ \dfrac{\mathrm{d}}{\mathrm{d}t} x_m(t) = \alpha x_m\big(r(t)\big) r'(t) \exp\big[-\gamma \tau\big(z\big(r(t)\big)\big)\big] - f\big(x_m(t)\big) x_m(t), \end{cases}$$

where $\gamma > 0$ and $f(x_m)$ are the mortality rates during the immature and mature stages. A detailed derivation of the above model and a careful analysis of conditions which assure existence, uniqueness, positiveness and boundedness of solutions can be found in [76], and the additional analysis such as the existence of steady-state solutions and how the delay affects stability can be found in [9,11].

Not much progress has been made for population dynamics involving both spatial dispersal and state-dependent delay, which would naturally involve certain types of partial functional differential equations. In [184], a new class of non-local partial functional differential equations is proposed for the evolution of a single species population that involves delayed feedback, where the delay such as the time length for reproduction, is selective and the selection depends on the status of the system. The abstract model in the work [184] is the following non-local partial differential equation with state-dependent selective delay:

$$\frac{\partial}{\partial t} u(t,x) + A u(t,x) + d u(t,x) = \big(F(u_t)\big)(x), \quad x \in \Omega, \tag{2.6.8}$$

where

$$\big(F(u_t)\big)(x) := \int_{-r}^{0} \left\{ \int_{\Omega} b\big(u(t+\theta, y)\big) f(x-y)\, \mathrm{d}y \right\} \xi\big(\theta, \|u(t)\|\big)\, \mathrm{d}\theta,$$

A is a densely-defined self-adjoint positive linear operator with domain $D(A) \subset L^2(\Omega)$ and with compact resolvent, Ω is a smooth bounded domain in $\mathbb{R}^n$, $f : (\Omega - \Omega) \to \mathbb{R}$ is a certain bounded function, $b : \mathbb{R} \to \mathbb{R}$ is a locally Lipschitz map and satisfies $|b(w)| \leqslant C_1 |w| + C_2$ with $C_1 \geqslant 0$ and $C_2 \geqslant 0$, d is a positive constant. The function $u(\cdot,\cdot) : [-r, +\infty) \times \Omega \to \mathbb{R}$ is given such that for any t the function $u(t) \equiv u(t,\cdot) \in L^2(\Omega)$, $\|\cdot\|$ is the $L^2(\Omega)$-norm. The function $\xi : [-r, 0] \times \mathbb{R} \to \mathbb{R}$ represents the state-selective delay, for example, if

$$\xi(\theta, s) = \mathrm{e}^{-\beta(g(s)-\theta)^2}, \quad \theta \in [-r, 0], \ s \in \mathbb{R},$$

then the function g gives the coordinate of the maximum of ξ. Thus the system selects the maximal historical impact on the current change rate according to the system's current state.

2.7. *Cell biology and hematological disorders*

The monograph [162] contains a brief discussion of a modified structured model for the control of the bone marrow stem cell population which supplies the circulating red blood cell population. For this case, the maturing stem cell population is structured by a maturation variable and the rate of maturation is assumed to depend only on the total mature red blood cell population. Since a threshold level of maturation is required in order for an immature cell to enter the population, a threshold delay differential equation arises naturally.

Age-structured models have also been used in the study of hematological disorders, and these models can be reduced via the method of characteristics to systems of threshold type differential delay equations, see [24,26,149,185]. Here we describe the work [149].

We first note that the precursor cells begin from a pool of burst-forming units of the erythroid line (BFU) that have differentiated into a self-sustaining population which eventually leads to the production of mature erythrocytes. At some point, the BFUs further differentiate and start down a proliferative path that can ultimately produce erythrocytes. Early in this proliferative phase of development the hormone Epo, alone with other hormones, affects the number of BFU that become erythrocytes. Increase in the concentration of Epo may increase the number of BFU recruited to mature into erythrocytes. Alternatively, there may be a relatively constant supply of committed BFU, but only the cells tagged with sufficient Epo survive the rapidly proliferating colony forming units (CFU) phase to complete maturation.

Let $p(t,\mu)$ denote the population of precursor cells at time t with age μ, and let $V(E)$ be the velocity of maturation, which may depend on the hormone concentration, E. The maturity level μ for erythropoiesis can represent the accumulation of hemoglobin in the precursor cells. If $S_0(E)$ is the number of cells recruited into the proliferating precursor population, then the entry of new precursor cells into the age-structured model satisfies the boundary condition

$$V(E)p(t,0) = S_0(E). \tag{2.7.1}$$

Let μ_F be the maximum age for a cell reaching maturity, then the dynamics of the precursor cells is governed by the age-structured model

$$\left(\frac{\partial}{\partial t} + V(E)\frac{\partial}{\partial \mu}\right)p(t,\mu) = \bigl[\beta(\mu,E) - H(\mu)\bigr]p(t,\mu), \quad t > 0,\ 0 < \mu < \mu_F, \tag{2.7.2}$$

where $\beta(\mu,E)$ is the net birth rate for proliferating precursor cells, and $H(\mu)$ is the disappearance rate given by

$$H(\mu) = \frac{h(\mu - \bar{\mu})}{\int_{\mu}^{\mu_F} h(s - \bar{\mu})\,\mathrm{d}s}$$

and $h(\mu - \bar{\mu})$ is the distribution of maturity levels of the cells when released into the circulating blood, with $\bar{\mu}$ being the mean age of mature precursor cells and the normalization $\int_0^{\mu_F} h(\mu - \bar{\mu})\,\mathrm{d}\mu = 1$.

Let $m(t, \nu)$ be the population of mature non-proliferating cells at time t and age ν, and assume the mature cells age at a constant rate W. The boundary condition for cells entering the maturation population is given by

$$Wm(t, 0) = V(E) \int_0^{\mu_F} h(\mu - \bar{\mu}) p(t, \mu)\,\mathrm{d}\mu. \tag{2.7.3}$$

The complete feedback involves the Epo level E, its growth is regulated by the total population of mature cells. Therefore, we need to determine the maximum age $\nu_F(t)$ of erythrocytes, which varies in t as the destruction of erythrocytes occurs by active removal of the oldest cells. We assume a constant erythrocyte removal rate Q, which can be justified by either assuming a constant supply of markers or a constant number of phagocytes that become satiated in their destruction of the oldest erythrocytes, then consideration of the moving boundary condition at $\nu = \nu_F(t)$ yields

$$\bigl(W - \nu_F'(t)\bigr)m\bigl(t, \nu_F(t)\bigr) = Q, \tag{2.7.4}$$

or equivalently,

$$\frac{\mathrm{d}}{\mathrm{d}t}\nu_F(t) = W - \frac{Q}{m(t, \nu_F(t))}. \tag{2.7.5}$$

To obtain this unusual moving boundary condition, we notice that when erythrocytes age, their cell membrane breaks down and marcophages destroy the least pliable cells. On the other hand, since we assume the macrophages are in constant supply and are saturated in their consumption of erythrocytes, the age of destruction of erythrocytes then varies. In particular, during the time interval $[t, t + \Delta t]$, one can use the Mean Value Theorem to find $\chi, \eta \in [t, t + \Delta t]$ so that

$$Q\Delta t + \bigl[\nu_F(t + \Delta t) - \nu_F(t)\bigr]m\bigl(\eta, \nu_F(\eta)\bigr) = W\Delta t m\bigl(\chi, \nu_F(\chi)\bigr)$$

from which (2.7.4) follows.

The dynamics of matured cells before its maximum age is governed by the age-structured model

$$\left(\frac{\partial}{\partial t} + W\frac{\partial}{\partial \nu}\right)m(t, \nu) = -W\gamma(\nu)m(t, \nu), \quad t > 0,\ 0 < \nu < \nu_F(t), \tag{2.7.6}$$

where $\gamma(\nu)$ is the age-dependent death rate of mature cells.

To complete the feedback cycle, we note that the Epo level E is governed by a negative feedback of the total population of mature cells

$$M(t) = \int_0^{\nu_F(t)} m(t, \nu)\,\mathrm{d}\nu, \tag{2.7.7}$$

via

$$\frac{\mathrm{d}}{\mathrm{d}t}E(t) = F\big(M(t)\big) - kE(t), \tag{2.7.8}$$

where k is the decay constant for the hormone and $F(M)$ is a monotonically decreasing function of M.

In the simple case, that we consider in the remaining part of this subsection, where $V(E) = W = 1$ and $\beta(\mu, E) = \beta(\mu)$ is independent of E, if the initial condition

$$p(0, \mu) = \phi(\mu), \qquad m(0, \nu) = \psi(\nu)$$

is given, then the method of characteristics yields that

$$p(t, \mu) = \begin{cases} \phi(\mu - t)\exp\left[\int_0^t F(\mu - t + w)\,\mathrm{d}w\right], & t < \mu; \\ S_0\big(E(t-\mu)\big)\exp\left[\int_{t-\mu}^t F(w - t + \mu)\,\mathrm{d}w\right], & t > \mu, \end{cases} \tag{2.7.9}$$

with $F(\mu) = \beta(\mu) - H(\mu)$, and

$$m(t, \nu) = \begin{cases} \psi(\nu - t)\exp\left[-\int_0^t (\nu + \sigma - t)\,\mathrm{d}\sigma\right], & t < \nu; \\ \int_0^{\mu_F} h(\mu - \bar{\mu})p(t - \nu, \mu)\,\mathrm{d}\mu \exp\left[-\int_0^\nu \gamma(\sigma)\,\mathrm{d}\sigma\right], & t > \nu. \end{cases} \tag{2.7.10}$$

If t is sufficiently large, then we get

$$M(t) = \int_0^{\nu_F(t)} \int_0^{\mu_F} h(\mu - \bar{\mu})p(t - \nu, \mu)\,\mathrm{d}\mu \exp\left[-\int_0^\nu \gamma(\sigma)\,\mathrm{d}\sigma\right]\mathrm{d}\nu. \tag{2.7.11}$$

Thus, (2.7.5), (2.7.8) and (2.7.11), with p given in (2.7.9) form a complete system of integro-differential equations with the delay ν_F being adaptive.

3. A framework for the initial value problem

3.1. *Preliminaries*

For differential delay equations with state-dependent delays it is less obvious than in case of time-invariant delays on which state space IVPs are well-posed. For initial data in the familiar space $C = C([-h, 0]; \mathbb{R}^n)$ solutions to equations with state-dependent delay are in general not unique in cases where for similar equations with constant delay the IVP is well-posed. Winston [216] gave the following example: The functions defined by

$$x(t) = t + 1 \quad \text{and} \quad x(t) = t + 1 - t^{3/2}$$

for small $t > 0$ both are solutions of the equation

$$x'(t) = -x\bigl(t - \bigl|x(t)\bigr|\bigr)$$

with initial values

$$x(t) = \begin{cases} -1, & \text{if } t \leqslant -1; \\ \frac{3}{2}(t+1)^{1/3} - 1, & \text{if } -1 < t \leqslant -\frac{7}{8}; \\ \frac{10}{7}t + 1, & \text{if } -\frac{7}{8} < t \leqslant 0. \end{cases}$$

Early results on existence, uniqueness, and continuous dependence for solutions of IVPs with state-dependent delays are due to Driver [57–62], who studied cases of the two-body problem of electrodynamics; see also work by Driver and Norris [64], Travis [198], and Hoag and Driver [111]. The latter investigated equations with both delayed and advanced state-dependent shifted arguments. Winston [216,218] studied uniqueness for special scalar equations, among others. Well-posed initial value problems are the basis for work on periodic solutions, notably by Nussbaum [174], Alt [4], Mallet-Paret and Nussbaum [151, 152,155], Kuang and Smith [136,137,190], Mallet-Paret, Nussbaum and Paraskevopoulos [156], Arino, Hadeler and Hbid [7], Krisztin and Arino [132], Magal and Arino [148], and in [205]. Further existence and uniqueness results are due to Gatica and Waltman [88,89] and Jackiewicz [119,121], and to Ito and Kappel [118] in an approach to more general IVPs. The delay differential and integral equations addressed in these results belong to special classes where the state-dependent delay appears explicitly or is defined implicitly by an additional equation. Typically, the IVP is uniquely solved for initial and other data which satisfy suitable Lipschitz conditions. Manitius [160] and Brokate and Colonius [29] deal with differentiability of operators given by the right-hand side of differential equations with state-dependent delay, in the context of control theory. Section 6 below reports about work of Hartung and Turi [106] who proved differentiability of solutions with respect to parameters—including Lipschitz continuous initial data—in Sobolev spaces and related quasi-normed spaces. Louihi, Hbid, and Arino [144] consider a class of equations with state-dependent delay in the framework of nonlinear semigroup theory. Their results are used in an approach of Ouifki and Hbid [178] to periodic solutions which is described in Section 8.3 below.

Let us now see where the difficulty with uniqueness arises if a given differential equation with state-dependent delay is written in the general form (1.0.1). Our discussion of the uniqueness problem will naturally lead us to a manifold on which Eq. (1.0.1) defines a continuous semiflow with continuously differentiable solution operators. We shall obtain continuously differentiable local stable and unstable manifolds of the semiflow at stationary points, also center manifolds for the solution operators, and a convenient Principle of Linearized Stability, among others.

We begin with an equation

$$x'(t) = g\big(x\big(t - r(x_t)\big)\big), \tag{3.1.1}$$

with a given map $g : \mathbb{R}^n \to \mathbb{R}^n$ and a given delay functional $r : U \to [0, h]$, for $h > 0$, $n \in \mathbb{N}$, and $U \subset (\mathbb{R}^n)^{[-h,0]}$. Equation (3.1.1) has the form (1.0.1) for

$$f = g \circ ev \circ \big(id \times (-r)\big)$$

where

$$ev : \big(\mathbb{R}^n\big)^{[-h,0]} \times [-h, 0] \to \mathbb{R}^n$$

is the evaluation map defined by

$$ev(\phi, s) = \phi(s).$$

Notice that the restriction of ev to $C \times [-h, 0]$ is not locally Lipschitz continuous: Lipschitz continuity would imply Lipschitz continuity of elements $\phi \in C$. Therefore in general f is not locally Lipschitz continuous on open subsets of C, and the familiar results on existence, uniqueness, and dependence of solutions on initial data and parameters for RFDEs from, say, [54,98] fail.

The difficulty just mentioned disappears if C is replaced by the smaller Banach space $C^1 = C^1([-h, 0]; \mathbb{R}^n)$ since the restricted evaluation map

$$Ev : C^1 \times [-h, 0] \ni (\phi, s) \mapsto \phi(s) \in \mathbb{R}^n$$

is continuously differentiable, with

$$\mathrm{D}_1 Ev(\phi, s)\chi = Ev(\chi, s) \quad \text{and} \quad \mathrm{D}_2 Ev(\phi, s)1 = \phi'(s).$$

So, for $g : \mathbb{R}^n \to \mathbb{R}^n$ and $r : U \to [0, h]$, $U \subset C^1$ open, both continuously differentiable, the resulting functional

$$f = g \circ Ev \circ \big(id \times (-r)\big)$$

is continuously differentiable from U to $\mathbb{R}^n$, with

$$\begin{aligned} \mathrm{D}f(\phi)\chi &= \mathrm{D}g\big(\phi\big(-r(\phi)\big)\big)\big[\mathrm{D}_1 Ev\big(\phi, -r(\phi)\big)\chi - \mathrm{D}_2 Ev\big(\phi, -r(\phi)\big)\mathrm{D}r(\phi)\chi\big] \\ &= \mathrm{D}g\big(\phi\big(-r(\phi)\big)\big)\big[\chi\big(-r(\phi)\big) - \mathrm{D}r(\phi)\chi\phi'\big(-r(\phi)\big)\big] \end{aligned}$$

for $\phi \in U$ and $\chi \in C^1$.

However, yet another obstacle is in the way. Suppose $U \subset C^1$ is open, $f : U \to \mathbb{R}^n$ is continuously differentiable, and the IVP

$$x'(t) = f(x_t) \quad \text{for } t > 0, \quad x_0 = \phi, \tag{3.1.2}$$

is well-posed for $\phi \in U$. A solution $x : [-h, t_e) \to \mathbb{R}^n$, $0 < t_e \leqslant \infty$, has segments $x_t \in U \subset C^1$, $0 \leqslant t < t_e$. Therefore x is continuously differentiable, and the curve $[0, t_e) \ni t \mapsto x_t \in C^1$ is continuous. Continuity at $t = 0$ yields

$$\phi'(0) = x'(0) = f(x_0) = f(\phi),$$

a necessary condition on initial data which may or may not be satisfied.

In any case, the last equation suggests to consider the IVP (3.1.2) for initial data only in the closed subset

$$X_f = \{\phi \in U\colon\ \phi'(0) = f(\phi)\}$$

of $U \subset C^1$.

From now on, a solution is understood to be a continuously differentiable function $x : [-h, t_*) \to \mathbb{R}^n$, $0 < t_* \leqslant \infty$, which satisfies $x_t \in U$ for $0 \leqslant t < t_*$, $x_0 = \phi$, and $x'(t) = f(x_t)$ for $0 < t < t_*$.

Incidentally, notice that X_f is a nonlinear analogue of the domain

$$\{\phi \in C^1\colon\ \phi'(0) = L\phi\}$$

of the generator of the semigroup given by the solutions to the linear IVP

$$y'(t) = Ly_t, \quad y_0 = \phi \in C,$$

for $L : C \to \mathbb{R}^n$ linear continuous [54,98].

3.2. *The semiflow on the solution manifold*

There is a mild smoothness condition (S) on the functional $f : U \to \mathbb{R}^n$, $U \subset C^1$ open, which is often satisfied if f represents an equation with state-dependent delay, and which implies all the desired results, namely

(S1) f is continuously differentiable,
(S2) each derivative $\mathrm{D}f(\phi)$, $\phi \in U$, extends to a linear map $\mathrm{D}_e f(\phi) : C \to \mathbb{R}^n$, and
(S3) the map

$$U \times C \ni (\phi, \chi) \mapsto \mathrm{D}_e f(\phi)\chi \in \mathbb{R}^n$$

is continuous.

Let us see what condition (S) means for the example

$$f = g \circ Ev \circ \big(id \times (-r)\big)$$

above, with $r : U \to [0, h]$, $U \subset C^1$ open, and $g : \mathbb{R}^n \to \mathbb{R}^n$ continuously differentiable. Suppose the delay functional r satisfies condition (S) (with $n = 1$). If then $\mathrm{D}_e f$ is defined by the formula above for $\mathrm{D}f$, with $\mathrm{D}r$ replaced by $\mathrm{D}_e r$, one sees that condition (S) holds for f. Notice that r satisfies (S) provided it is the restriction of a continuously differentiable map $V \to [0,h]$, $V \subset C$ open, to $U = V \cap C^1$.

THEOREM 3.2.1. *Suppose $U \subset C^1$ is open, $f : U \to \mathbb{R}^n$ has property* (S), *and $X_f \neq \emptyset$. Then X_f is a continuously differentiable submanifold of U with codimension n, and each $\phi \in X_f$ uniquely defines a noncontinuable solution $x^\phi : [-h, t_+(\phi)) \to \mathbb{R}^n$ of the IVP* (3.1.2). *All segments x_t^ϕ, $0 \leqslant t < t_+(\phi)$ and $\phi \in X_f$, belong to X_f, and the relations*

$$F(t,\phi) = x_t^\phi, \quad \phi \in X_f,\ 0 \leqslant t < t_+(\phi)$$

define a domain $\Omega \subset \mathbb{R} \times X_f$ and a continuous semiflow $F : \Omega \to X_f$. Each map

$$F(t,\cdot) : \{\phi \in X_f\colon\ (t,\phi) \in \Omega\} \to X_f$$

is continuously differentiable, and for all $(t,\phi) \in \Omega$ and $\chi \in T_\phi X_f$ we have

$$\mathrm{D}_2 F(t,\phi)\chi = v_t^{\phi,\chi}$$

with the solution $v^{\phi,\chi} : [-h, t_+(\phi)) \to \mathbb{R}^n$ of the linear IVP

$$v'(t) = \mathrm{D}f\bigl(F(t,\phi)\bigr)v_t, \quad v_0 = \chi. \tag{3.2.1}$$

At each (t,ϕ) with $\phi \in X_f$ and $h < t < t_+(\phi)$, the partial derivative $\mathrm{D}_1 F(t,\phi)$ *exists, and*

$$\mathrm{D}_1 F(t,\phi)1 = \bigl(x_t^\phi\bigr)'.$$

The restriction of F to the submanifold $\{(t,\phi) \in \Omega\colon\ h < t\}$ of $\mathbb{R} \times X_f$ is continuously differentiable.

Notice that the tangent spaces of the manifold X_f are given by

$$T_\phi X_f = \{\chi \in C^1\colon\ \chi'(0) = \mathrm{D}f(\phi)\chi\}.$$

Theorem 3.2.1 is proved in [206,207]. The construction of the semiflow is also sketched in [209].

The first part (S1) of the hypothesis and continuity of each extension $\mathrm{D}_e f(\phi)$ suffice for X_f to be a continuously differentiable submanifold. The proof of this is simple: For

$$p : C^1 \ni \phi \mapsto \phi'(0) \in \mathbb{R}^n,$$

$$X_f = (p - f)^{-1}(0),$$

and the Implicit Function Theorem yields local representations of X_f as graphs over the kernels of the linear maps $\mathrm{D}(p - f)(\phi) = p - \mathrm{D}f(\phi))$, $\phi \in X_f$, provided these linear maps are surjective. In case $n = 1$ surjectivity follows since using the continuity of $\mathrm{D}_e f(\phi)$ at $0 \in C$ one finds $\chi \in C^1 \subset C$ with $\chi'(0) = 1$ and $\mathrm{D}f(\phi)\chi = \mathrm{D}_e f(\phi)\chi < 1 = p\chi$, which gives $(p - \mathrm{D}f(\phi))C^1 = \mathbb{R}$. In case $n > 1$ similar arguments yield a basis of $\mathbb{R}^n$ in $(p - \mathrm{D}f(\phi))C^1$.

Condition (S3) implies that the map $D_e f$ is locally bounded. From this one derives easily the following local Lipschitz property:

(L) For every $\phi \in U$ there are a neighbourhood V and $L \geqslant 0$ with $|f(\psi) - f(\chi)| \leqslant L\|\psi - \chi\|_C$ for all $\psi \in V$, $\chi \in V$,

see Corollary 1 in [207]. Notice that the last norm is the norm on C and not the larger norm on the smaller space C^1. So (L) is not a consequence of (S1). Property (L) (together with (S1), (S2) and continuity of each $\mathrm{D}_e f(\phi)$) yields existence and continuity of the semiflow as well as the properties of the maps $F(t,\cdot)$ stated in Theorem 3.2.1. Only for the two last statements of Theorem 3.2.1, on smoothness, the full hypothesis (S) is needed.

It is worth noting that continuity of the map

$$U \ni \phi \mapsto \mathrm{D}_e f(\phi) \in L\big(C, \mathbb{R}^n\big),$$

which seems only slightly stronger than property (S3) above, does in general *not* hold for functionals f which represent differential equations with state-dependent delay.

A key issue in the proof of Theorem 3.2.1 is how the local Lipschitz property (L) is used for the construction of local solutions to the IVP. Let us briefly explain this.

In order to solve the integrated version

$$x(t) = \phi(0) + \int_0^t f(x_s)\,\mathrm{d}s, \quad x_0 = \phi \in X_f,$$

of the IVP for $0 \leqslant t \leqslant T$ by a continuously differentiable map

$$x : [-h, T] \to \mathbb{R}^n,$$

which is continuously differentiable with respect to ϕ, the desired solution is first written as the sum of a linear, continuously differentiable continuation $\hat{\phi}$ of ϕ and of a function u which is zero on $[-h, 0]$. The fixed point problem for u is

$$u(t) = \int_0^t \big(f\big(u_s + \hat{\phi}_s\big) - f(\phi)\big)\,\mathrm{d}s, \quad 0 \leqslant t \leqslant T.$$

The advantage of this formulation is that for the operator $u \mapsto A(\phi, u)$ given by the right hand side dependence on ϕ is more explicit than in the equation for x. For $A(\phi,\cdot)$ to become a contraction with respect to the norm $\|u\|_{T,1} = \max_{0\leqslant s\leqslant T}|u(s)| + \max_{0\leqslant s\leqslant T}|u'(s)|$ we use the following estimate for $v = A(\phi, u)$, $\overline{v} = A(\phi, \overline{u})$, and $0 \leqslant t \leqslant T$:

$$\big|v'(t) - \overline{v}'(t)\big| = \big|f\big(u_t + \hat{\phi}_t\big) - f\big(\overline{u}_t + \hat{\phi}_t\big)\big| \leqslant L\|u_t - \overline{u}_t\|_C$$

(due to the local Lipschitz property, for T and u and $\overline{u}$ small)

$$\leqslant L \max_{0\leqslant s\leqslant T} \bigl|u(s) - \overline{u}(s)\bigr| = L \max_{0\leqslant s\leqslant T} \left| \int_0^s \bigl(u'(r) - \overline{u}'(r)\bigr)\,\mathrm{d}r \right| \leqslant LT\|u - \overline{u}\|_{T,1}.$$

The proof that the semiflow F is continuously differentiable on the manifold given by $t > h$ is based on growth estimates and smoothness properties of solutions to the IVP

$$v'(t) = \mathrm{D}_e f\bigl(F(t,\phi)\bigr)v_t, \quad v_0 = \chi \tag{3.2.2}$$

for initial data $\chi \in C$.

The previous result is optimal in the sense that typically the semiflow F has no partial derivatives with respect to the first variable for $0 \leqslant t < h$.

The framework presented up to here is instrumental in the proof in [208] that for a certain differential system with state-dependent delay, which models position control by echo, hyperbolic stable periodic orbits exist.

With regard to results for solutions $x : [-h, t_+) \to \mathbb{R}^n$ to equations of the form (3.1.1) and generalizations thereof in the sense that x is continuous but differentiable only for $0 < t < t_+$, notice that for $h \leqslant t < t_+$ we have

$$x_t \in X_f$$

(with $f = g \circ ev \circ (id \times (-r))$ in case of Eq. (3.1.1)), so all dynamical properties like structure and stability of invariant sets (stationary points, periodic orbits, unstable manifolds, global attractors, ...) are determined by the semiflow F on X_f—provided the mild smoothness condition (S) holds.

Some notions of the approach to well-posedness and smoothness which we described here are related to ideas from earlier work. The Lipschitz property (L) from the proof of Theorem 3.2.1 was used before in [205] and is analogous to the notion of being *locally almost Lipschitzian* from [156]. The condition that (S1) holds and each $\mathrm{D}_e f(\phi)$ is continuous was introduced in [156] as *almost Fréchet differentiability*. It also is a special case of a smoothness condition used in [129]. Sets analogous to X_f were considered in [134] as state space for neutral functional differential equations, and by Louihi, Hbid and Arino [144]. In [144] the IVP for a certain class of equations of the form (3.1.1) defines a semigroup of locally Lipschitz continuous solution operators on the space $C^{0,1}$. The positively invariant subset $E \subset C^{0,1}$ of data $\phi \in C^1$ with $\phi'(0) = g(\phi(-r(\phi)))$ is identified as the domain of strong continuity of the semigroup. In the present notation, $E = X_f$ for $f = g \circ Ev \circ (id \times (-r))$. It is stated in [144] that E is a Lipschitz manifold.

3.3. *Compactness*

Recall that a map from a subset of a Banach space into a Banach space is called compact if images of bounded sets have compact closure. A simple compactness result for the semiflow of Theorem 3.2.1 is the following. Notice in which way the hypotheses strengthen property (S).

PROPOSITION 3.3.1. *Suppose $f : U \to \mathbb{R}^n$, $U \subset C^1$ open, is bounded, satisfies condition* (S), *and*

(Lb) *for every bounded set $B \subset U$ there exists $L_B \geqslant 0$ with $|f(\phi) - f(\psi)| \leqslant L_B \|\phi - \psi\|_C$ for all ϕ, ψ in B.*

Then all maps $F(t, \cdot)$, $t \geqslant h$, are compact.

PROOF. Let $t \geqslant h$ and let a bounded set $B \subset \{\phi \in X_f\colon (t, \phi) \in \Omega\}$ be given. In order that $\overline{F(t, B)} \subset C^1$ be compact it is enough to show that every sequence in $F(t, B)$ has a convergent subsequence, which follows by means of the Ascoli–Arzelà Theorem provided both sets $M = \{x_t^\phi \in C^1\colon \phi \in B\}$ and $M' = \{(x_t^\phi)' \in C\colon \phi \in B\}$ are bounded with respect to the norm $\|\cdot\|_C$ and equicontinuous. The boundedness of B and f in combination with Eq. (1.0.1) shows that

$$b = \sup_{\phi \in B, -h \leqslant s \leqslant t} \left|\left(x^\phi\right)'(s)\right| < \infty.$$

Then the boundedness of B and integration yield

$$\sup_{\phi \in B, -h \leqslant s \leqslant t} \left|x^\phi(s)\right| < \infty.$$

In particular, M' and M are bounded with respect to $\|\cdot\|_C$. The boundedness of M' yields the equicontinuity of M. We also have that the set

$$Y = \left\{F(s, \phi)\colon \phi \in B, 0 \leqslant s \leqslant t\right\} \subset X_f \subset U$$

is bounded with respect to $\|\cdot\|_{C^1}$. Now equicontinuity of M' follows from the estimate

$$\begin{aligned}
\left|\left(x_t^\phi\right)'(s) - \left(x_t^\phi\right)'(u)\right| &= \left|\left(x^\phi\right)'(t+s) - \left(x^\phi\right)'(t+u)\right| \\
&= \left|f\left(F(t+s, \phi)\right) - f\left(F(t+u, \phi)\right)\right| \\
&\leqslant L_Y \left\|F(t+s, \phi) - F(t+u, \phi)\right\|_C \\
&= L_Y \max_{-h \leqslant v \leqslant 0} \left|x^\phi(t+s+v) - x^\phi(t+u+v)\right| \\
&= L_Y \max_{-h \leqslant v \leqslant 0} \left|\int_{t+u+v}^{t+s+v} (x^\phi)'(w)\,\mathrm{d}w\right| \leqslant L_Y b|s-u|
\end{aligned}$$

for all $\phi \in B$ and all s, u in $[-h, 0]$. □

In case of the example $f = g \circ Ev \circ (id \times (-r))$ with $r : U \to [0, h]$, $U \subset C^1$ open, and $g : \mathbb{R}^n \to \mathbb{R}^n$ continuously differentiable the hypotheses of Proposition 3.3.1 are satisfied if in addition U is convex, r has property (S), g is bounded, and $\mathrm{D}_e r$ and $\mathrm{D}g$ map bounded sets onto bounded sets: The boundedness of f is obvious. The formula which computes $\mathrm{D}_e f$ from $\mathrm{D}g$ and $\mathrm{D}_e r$ shows that $\mathrm{D}_e f$ maps bounded sets onto bounded subsets. For a given bounded set $B \subset U$ there is a larger convex bounded subset $B^* \subset U$, and for ϕ, ψ in B^* we have

$$\begin{aligned}\left|f(\phi) - f(\psi)\right| &= \left|\int_0^1 \mathrm{D}f\big(\psi + t(\phi - \psi)\big)(\phi - \psi)\,\mathrm{d}t\right| \\ &= \left|\int_0^1 \mathrm{D}_e f\big(\psi + t(\phi - \psi)\big)(\phi - \psi)\,\mathrm{d}t\right| \\ &\leqslant \int_0^1 \left|\mathrm{D}_e f\big(\psi + t(\phi - \psi)\big)(\phi - \psi)\right|\mathrm{d}t \\ &\leqslant \sup_{\chi \in B^*} \left\|\mathrm{D}_e f(\chi)\right\| \|\phi - \psi\|_C,\end{aligned}$$

which yields property (Lb).

For another result on compactness, for solution operators on the space $C^{0,1}$, see [144].

3.4. *Linearization at equilibria*

Theorem 3.2.1 reveals in particular how to linearize semiflows defined by differential equations with state-dependent delay, an issue which had been mysterious before. Consider $f : U \to \mathbb{R}^n$, $U \subset C^1$ open, with property (S). Let a stationary point $\phi_0 \in X_f$ of the semiflow F from Theorem 3.2.1 be given. The linearization of F at ϕ_0 is the semigroup T of the linear continuous operators $T(t) = \mathrm{D}_2 F(t, \phi_0)$, $t \geqslant 0$, on the Banach space $T_{\phi_0} X_f$ with the norm $\|\cdot\|_{C^1}$. T is strongly continuous since the solutions $v^{\phi_0,\chi} : [-h, \infty) \to \mathbb{R}^n$ of the IVP (3.2.1) with $\chi \in T_{\phi_0} X_f$ are continuously differentiable.

Before the present approach was available a heuristic technique had been developed in order to circumvent the linearization problem in studies of local stability and instability properties of equilibria. This technique associates to the given nonlinear equation an auxiliary linear equation in the following way: First the delay is frozen at equilibrium, then the resulting nonlinear equation with constant delay is linearized. Of course, this makes sense only for equations where the delay appears explicitly, like, e.g., in Eq. (3.1.1). Let us use Eq. (3.1.1) to show that the auxiliary equation found by the heuristic technique is

$$v'(t) = \mathrm{D}_e f(\phi_0) v_t$$

in our framework. Suppose for simplicity that $n = 1$, that $g : \mathbb{R} \to \mathbb{R}$ satisfies $g(0) = 0$ and that g and the delay functional $r : U \to [0, h]$, $U \subset C^1$ open, are continuously differentiable. Freezing the delay in Eq. (3.1.1) at $\phi_0 = 0$ and linearizing the resulting RFDE

$$x'(t) = g\big(x\big(t - r(0)\big)\big)$$

at the zero solution yields

$$v'(t) = g'(0) v\big(t - r(0)\big).$$

On the other hand, for the functional $f_{g,r} = g \circ Ev \circ (id \times (-r))$ and $\chi \in C^1$ the computation of derivatives above yields

$$\mathrm{D} f_{g,r}(0)\chi = \mathrm{D}g(0)\chi\big(-r(0)\big) = g'(0)\chi\big(-r(0)\big).$$

Obviously the right-hand side of this equation defines a continuous linear extension $\mathrm{D}_e f_{g,r}(0) : C \to \mathbb{R}$ of $\mathrm{D} f_{g,r}(0)$, which verifies our previous statement. In other words, the auxiliary equation found by the heuristic method yields the true linear variational equation by restriction to the tangent space $T_0 X_f$.

In the sequel we clarify the relation between the spectral properties of the linearization T of the semiflow F of Theorem 3.2.1 at a stationary point $\phi_0 \in X_f$ and the strongly continuous semigroup T_e on the space C which is defined by the solutions of the IVP (3.2.2). Recall that the generator $G_e : dom \to C$ of T_e is given by $dom = \{\phi \in C^1 \colon\ \phi'(0) = D_e f(\phi_0)\phi\}$ and $G_e\phi = \phi'$.

We have $T_{\phi_0} X_f = dom$, $T(t)\phi = T_e(t)\phi$ for $t \geqslant 0$ and $\phi \in dom$, and the norm $\|\cdot\|_{C^1}$ coincides with the graph norm $\|\cdot\|_e = \|\cdot\|_C + \|G_e \cdot\|_C$ of the operator G_e.

It is a simple general fact that for a strongly continuous semigroup S of linear continuous operators on a Banach space B, with generator $A : D_A \to B$, the induced linear operators

$$D_A \ni x \mapsto S(t)x \in D_A$$

are continuous with respect to the graph norm $\|\cdot\|_A = \|\cdot\| + \|A\cdot\|$ and form a strongly continuous semigroup on the Banach space $(D_A, \|\cdot\|_A)$, with the generator A_d defined on the domain

$$D_d = \{x \in D_A \colon\ Ax \in D_A\}$$

of A^2 and given by $A_d x = Ax$. Proofs are immediate from $S(t)D_A \subset D_A$ and

$$S(t)Ax = AS(t)x \quad \text{on } D_A$$

for all $t \geqslant 0$.

Our semigroups and their generators are precisely in the relation just described, so we have

$$\begin{aligned} D = (D_d =) &\left\{\chi \in C^1 \colon\ \chi'(0) = \mathrm{D}f(\phi_0)\chi,\, \chi' \in C^1,\, \chi''(0) = \mathrm{D}f(\phi_0)\chi'\right\} \\ &= \left\{\chi \in C^2 \colon\ \chi'(0) = \mathrm{D}f(\phi_0)\chi,\, \chi''(0) = \mathrm{D}f(\phi_0)\chi'\right\} \end{aligned}$$

and $G\chi = \chi'$ on D.

We return to the general case. Below, ρ and σ denote resolvent sets and spectra, respectively.

PROPOSITION 3.4.1. *Suppose B is a Banach space over $\mathbb{C}$, S is a strongly continuous semigroup on B with generator $A : D_A \to B$, and A_d is the generator of the semigroup induced on the Banach space $(D_A, \|\cdot\|_A)$. Then the following holds.*

(i) *$\rho(A) \subset \rho(A_d) \subset \rho(A) \cup \{\lambda \in \mathbb{C}\colon\ A - \lambda I$ injective and $(A - \lambda I)D_A \neq B\}$, and $\sigma(A_d) \subset \sigma(A)$. For all $\lambda \in \rho(A)$, $(A_d - \lambda I)^{-1}x = (A - \lambda I)^{-1}x$ on D_A.*

(ii) *Let γ be a simple closed curve in $\rho(A)$ and let $\sigma_{\gamma,d} = int(\gamma) \cap \sigma(A_d)$, $\sigma_\gamma = int(\gamma) \cap \sigma(A)$. Then the spectral projections P_d, P and generalized eigenspaces $\mathcal{G}_d = P_d D_A$, $\mathcal{G} = PB$ associated with the sets $\sigma_{\gamma,d} \subset \sigma(A_d)$ and $\sigma_\gamma \subset \sigma(A)$, respectively, satisfy*

$$P_d x = Px \quad \text{on } D_A, \quad \mathcal{G}_d \subset \mathcal{G}, \quad \text{and} \quad \overline{\mathcal{G}_d}^B = \mathcal{G}.$$

PROOF. 1. Proof of (i).

1.1. Let $\lambda \in \rho(A)$ be given. The continuity of the inverse with respect to the norm on B and the definition of the graph norm combined show that for all $y \in D_A$ we have

$$\begin{aligned}\left\|(A - \lambda I)^{-1}y\right\|_A &= \left\|(A - \lambda I)^{-1}y\right\| + \left\|A(A - \lambda I)^{-1}y\right\| \\ &\leqslant \left\|(A - \lambda I)^{-1}y\right\| + \left\|(A - \lambda I)(A - \lambda I)^{-1}y\right\| \\ &\quad + \left\|\lambda(A - \lambda I)^{-1}y\right\| \\ &\leqslant \big((1 + |\lambda|)\left\|(A - \lambda I)^{-1}\right\| + 1\big)\|y\|.\end{aligned}$$

It follows that $(A - \lambda I)^{-1}$ defines a linear continuous map R from $(D_A, \|\cdot\|_A)$ into itself. The range of R contains the domain D_d of the generator A_d since for any $x \in D_A$ with $Ax \in D_A$ we have that $y = (A_d - \lambda I)x = (A - \lambda I)x \in D_A$, hence $x = (A - \lambda I)^{-1}y \in (A - \lambda I)^{-1}D_A = RD_A$.

Conversely, for $x = Ry = (A - \lambda I)^{-1}y$ with $y \in D_A$ we have $x \in D_A$ and $(A - \lambda I)x = y \in D_A$, hence $Ax = \lambda x + y \in D_A$, or $x \in D_d$.

So R maps D_A injectively onto the domain D_d of A_d. We have $R(A_d - \lambda I)y = R(A - \lambda I)y = y$ on D_d, $(A_d - \lambda I)Rx = (A - \lambda I)Rx = x$ on D_A, and it follows that $\lambda \in \rho(A_d)$ and $(A_d - \lambda I)^{-1}y = (A - \lambda I)^{-1}y$ on D_A.

The shown inclusion of resolvent sets yields the asserted result for spectra.

1.2. Proof of the remaining inclusion. Let $\lambda \in \rho(A_d)$ be given. $A - \lambda I$ is injective since $(A - \lambda I)x = 0$ implies $Ax \in D_A$, or $x \in D_d$, and therefore $(A_d - \lambda I)x = (A - \lambda I)x = 0$, which in turn gives $x = 0$, by $\lambda \in \rho(A_d)$.

Consider the injective continuous map

$$A_c\colon \big(D_A, \|\cdot\|_A\big) \ni x \mapsto (A - \lambda I)x \in B.$$

In case $(A - \lambda I)D_A = B$ the open mapping theorem shows that the inverse of A_c is continuous, which implies that

$$B \ni y \mapsto (A - \lambda I)^{-1}y \in B$$

is continuous. So in this case, $\lambda \in \rho(A)$, and the assertion becomes obvious.

2. Proof of (ii). The representation of $P_d x$ and Px, $x \in D_A$, as contour integrals in $(D_A, \| \cdot \|_A)$ and B, respectively, along the curve γ with integrands given by

$$(A_d - \lambda I)^{-1} x = (A - \lambda I)^{-1} x, \quad \lambda \in |\gamma|,$$

shows that $P_d x = Px$ on D_A. Consequently,

$$\mathcal{G}_d = P_d D_A \subset P D_A \subset PB = \mathcal{G},$$

and finally

$$\overline{\mathcal{G}_d}^B = \overline{P_d D_A}^B = \overline{P D_A}^B = PB$$

(since $\overline{D_A} = B$ and since P has closed range)

$$= \mathcal{G}. \qquad \square$$

It is easy to see that for a given semiflow S on a Banach space B over $\mathbb{R}$ and its generator $A : D_A \to B$, the complexification $A_{\mathbb{C}}$ of A coincides with the generator of the complexified semigroup $S_{\mathbb{C}} : t \mapsto S(t)_{\mathbb{C}}$, and that the semigroup induced by $S_{\mathbb{C}}$ on $(D_A)_{\mathbb{C}}$ is generated by the complexification of the generator $A_d : D_d \to (D_A, \| \cdot \|_A)$.

Returning to our case of semigroups T_e on C, T on $T_{\phi_0} X_f$ and their generators G_e, G, respectively, we recall that the embedding $(dom, \| \cdot \|_e) \to C$ is compact, by the Ascoli–Arzelà theorem. This yields that all resolvents of $(G_e)_{\mathbb{C}}$, which define continuous maps from $C_{\mathbb{C}}$ onto the complexification of the Banach space $(dom, \| \cdot \|_e)$, are compact. Therefore $\sigma(G_e) := \sigma((G_e)_{\mathbb{C}})$ is discrete and consists of eigenvalues with finite-dimensional generalized eigenspaces. Using Proposition 3.4.1 and the remarks following it we infer

$$\rho(G) = \rho(G_e), \qquad \sigma(G) = \sigma(G_e),$$

and for the spectral projections and generalized eigenspaces of $G_{\mathbb{C}}$ and $(G_e)_{\mathbb{C}}$ which are associated with $\lambda \in \sigma(G) = \sigma(G_e)$,

$$P(\lambda)\chi = P_e(\lambda)\chi \quad \text{on } T_{\phi_0} X_f = dom,$$

$$\mathcal{G}(\lambda) = \mathcal{G}_e(\lambda).$$

Recall that to the right of any line parallel to the imaginary axis there are at most a finite number of eigenvalues of G_e. Let C_u and C_c denote the unstable and center spaces of G_e, i.e., the finite-dimensional realified generalized eigenspaces given by the eigenvalues with positive real part and on the imaginary axis, respectively. The stable space C_s of G_e is the realified generalized eigenspace given by the spectrum with negative real part. More precisely, C_s is the realification of the space $(id - P_{\geqslant 0}) C_{\mathbb{C}}$ where $P_{\geqslant 0} : C_{\mathbb{C}} \to \mathbb{C}_{\mathbb{C}}$ denotes the spectral projection associated with the finite spectral set of all $\lambda \in \sigma(G_e)$ with $Re\lambda \geqslant 0$. We have

$$C_u \oplus C_c \subset D \subset dom = T_{\phi_0} X_f$$

while the infinite-dimensional, complementary space C_s is not contained in *dom*. Using the previous relations between spectral projections and generalized eigenspaces of the generators G and G_e it follows easily that the unstable and center spaces of G coincide with C_u and C_c, respectively, and that the stable space of G is

$$C_s \cap dom.$$

For each map $F(t,\cdot)$, $t > 0$, we have

$$\sigma\big(\mathrm{D}F(t,\cdot)(\phi_0)\big) = \sigma\big(T(t)\big) \subset \{0\} \cup \big\{\mathrm{e}^{zt}\colon\ z \in \sigma(G)\big\}, \tag{3.4.1}$$

and the linear unstable, center, and stable spaces for the derivative $\mathrm{D}F(t,\cdot)(\phi_0) = \mathrm{D}_2F(t,\phi_0) = T(t)$, which are defined by the eigenvalues outside, on, and inside the unit circle, are

$$C_u,\ C_c,\ \text{and } C_s \cap T_{\phi_0}X_f,\ \text{respectively.}$$

3.5. *Local invariant manifolds at stationary points*

Consider $f: U \to \mathbb{R}^n$, $U \subset C^1$ open, with property (S) and the associated semiflow $F: \Omega \to X_f$ of Theorem 3.2.1. It is convenient to set

$$\Omega_t = \big\{\phi \in X_f\colon\ (t,\phi) \in \Omega\big\} \quad \text{and} \quad F_t = F(t,\cdot),$$

for each $t \geqslant 0$. A stationary point $\phi_0 \in X_f$ of the semiflow F is a fixed point for each map $F_t: \Omega_t \to X_f$, $t > 0$. Results about local invariant manifolds for continuously differentiable maps on open subsets of Banach spaces [97,44,171,133] yield continuously differentiable local stable, center, and unstable manifolds

$$W_s \subset X_f, \quad W_c \subset X_f, \quad W_u \subset X_f$$

of F_t $t > 0$, at the fixed point ϕ_0, with tangent spaces at ϕ_0 given by

$$T_{\phi_0}W_s = C_s \cap T_{\phi_0}X_f, \qquad T_{\phi_0}W_c = C_c, \qquad T_{\phi_0}W_u = C_u.$$

In the sequel we recall details of this and use them to show that local stable manifolds W_s of any map F_a, $a > 0$, provide local stable manifolds of the semiflow F at the given stationary point. The last fact is familiar for flows of continuously differentiable vector fields in finite dimensions, but here we are concerned with semiflows on a Banach manifold of infinite dimension, and some care should be taken which properties of the underlying delay differential equation (1.0.1) ensure the result.

For local unstable manifolds an analogous result holds, and the proof is similar. Existence of smooth local center manifolds for the semiflow is more difficult, and the relationship between center manifolds of its time-t-maps and center manifolds for the semiflow is more subtle. This will be discussed in the next section.

So let a stationary point $\phi_0 \in X_f$ of the semiflow F be given. Recall from the preceding subsection the linear stable, center, and unstable spaces

$$C_s \cap T_{\phi_0} X_f, C_c, C_u$$

of the generator G of the semigroup T on $T_{\phi_0} X_f$. Choose $\beta > 0$ so that

$$-\beta > \max\left\{Re\, z\colon\ z \in \sigma(G), Re\, z < 0\right\}.$$

Let $a > 0$. In order to introduce the local stable manifold of the map $F_a : \Omega_a \to X_f$ at the fixed point ϕ_0 we use a manifold chart of X_f at ϕ_0. Let $Y = T_{\phi_0} X_f$. There is a subspace $E \subset C^1$ of dimension n which is a complement of Y in C^1. Let $P : C^1 \to C^1$ denote the projection along E onto Y. Then the equation $K(\phi) = P(\phi - \phi_0)$ defines a manifold chart on an open neighbourhood V of ϕ_0 in $\Omega_a \subset X_f$, with $Y_0 = K(V)$ an open neighbourhood of $0 = K(\phi_0)$ in the Banach space Y (with the norm given by $\|\cdot\|_{C^1}$). The inverse of K is given by a continuously differentiable map $R : Y_0 \to C^1$. Both derivatives $\mathrm{D}K(\phi_0)$ and $\mathrm{D}R(0)$ are given by the identity on Y. We may assume that there is a Lipschitz constant $L_R \geqslant 0$ so that

$$\left\|R(\chi) - R(\psi)\right\|_{C^1} \leqslant L_R \|\chi - \psi\|_{C^1} \quad \text{for all } \chi \in Y_0, \psi \in Y_0.$$

Choose an open neighbourhood $Y_1 \subset Y_0$ of 0 in Y with $F_a(R(Y_1)) \subset V$. In local coordinates the map F_a is represented by the continuously differentiable map

$$H : Y_1 \ni \chi \mapsto K\bigl(F_a\bigl(R(\chi)\bigr)\bigr) \in Y.$$

Obviously, $H(0) = 0$, $\mathrm{D}H(0) = \mathrm{D}F_a(\phi_0) = T(a)$, and $H(Y_1) \subset Y_0$. Using the last statement of the preceding subsection we infer that the linear stable, center, and unstable spaces of H at its fixed point $0 \in Y_1$ are $C_s \cap Y$, C_c, and C_u, respectively. Set $\lambda = \mathrm{e}^{-a\beta}$. Then (3.4.1) gives

$$\max\left\{|\zeta|\colon\ \zeta \in \sigma\bigl(\mathrm{D}H(0)\bigr), |\zeta| < 1\right\} < \lambda < 1.$$

The Stable Manifold Theorem (see Theorem I.2 in [133]) yields the following result.

PROPOSITION 3.5.1. *There exist* $\alpha \in (0, \lambda)$, *convex open neighbourhoods* $C_{s,2}$ *of* 0 *in* $C_s \cap Y$ *and* $C_{cu,2}$ *of* 0 *in* $C_c \oplus C_u$ *with* $N = C_{s,2} + C_{cu,2} \subset Y_2$, *a continuously differentiable map* $w : C_{s,2} \to C_{cu,2}$ *with* $w(0) = 0$ *and* $\mathrm{D}w(0) = 0$, *and an equivalent norm* $\|\cdot\|_H$ *on* Y *such that the following holds.*

(i) *The graph* $W = \{\chi + w(\chi)\colon\ \chi \in C_{s,2}\}$ *is equal to the set of all initial points* $\psi = \psi_0$ *of trajectories* $(\psi_j)_0^\infty$ *of* H *which satisfy* $\lambda^{-j}\psi_j \in N$ *for all* $j \in \mathbb{N}_0$ *and* $\lambda^{-j}\psi_j \to 0$ *as* $j \to \infty$.

(ii) $H(W) \subset W$.

(iii) $\|H(\phi) - H(\psi)\|_H \leqslant \alpha\|\phi - \psi\|_H$ *for all* $\psi \in W$, $\phi \in W$.

(iv) *For every trajectory* $(\psi_j)_0^\infty$ *of* H *with* $\lambda^{-j}\psi_j \in N$ *for all* $j \in \mathbb{N}_0$,

$$\psi_0 \in W.$$

Here, trajectories are defined by the equations $\psi_{j+1} = H(\psi_j)$ for all integers $j \geqslant 0$. The local stable manifold of F_a at ϕ_0 is the continuously differentiable submanifold

$$W_s = R(W)$$

of X_f. Obviously, $W_s \subset V$, $\phi_0 \in W_s$, and $T_{\phi_0}W_s = C_s \cap Y = C_s \cap T_{\phi_0}X_f$.

COROLLARY 3.5.2.

(i) $F_a(W_s) \subset W_s$, *and each neighbourhood of* ϕ_0 *in* W_s *contains a neighbourhood* $W_{s,1}$ *of* ϕ_0 *in* W_s *with* $F_a(W_{s,1}) \subset W_{s,1}$.

(ii) *There exists* $c_s \geqslant 0$ *so that for every trajectory* $(\psi_j)_0^\infty$ *of* F_a *in* W_s *and for all integers* $j \geqslant 0$,

$$\|\psi_j - \phi_0\|_{C^1} \leqslant c_s\alpha^j\|\psi_0 - \phi_0\|_{C^1}.$$

PROOF. 1. The first inclusion in assertion (i) follows from

$$K\bigl(F_a(W_s)\bigr) = K\bigl(F_a\bigl(R(W)\bigr)\bigr) = H(W) \subset W = K\bigl(R(W)\bigr)$$

by application of R. Proof of the second part of (i): For $\epsilon > 0$, set

$$Y_{H,\epsilon} = \bigl\{\psi \in Y\colon\ \|\psi\|_H < \epsilon\bigr\}.$$

Any given neighbourhood of ϕ_0 in $V \subset X_f$ contains $V_\epsilon = R(Y_{H,\epsilon})$ for some $\epsilon > 0$, and $R(W \cap Y_{H,\epsilon}) = R(W) \cap R(Y_{H,\epsilon}) = W_s \cap V_\epsilon$. Part (iii) of Proposition 3.5.1 yields $F_a(W_s \cap V_\epsilon) = R(K(F_a(R(W \cap Y_{H,\epsilon})))) = R(H(W \cap Y_{H,\epsilon})) \subset R(W \cap Y_{H,\epsilon}) = W_s \cap V_\epsilon$.

2. Proof of assertion (ii). There are positive constants $c_1 \leqslant c_2$ with

$$c_1\|\chi\|_{C^1} \leqslant \|\chi\|_H \leqslant c_2\|\chi\|_{C^1} \quad \text{for all } \chi \in Y.$$

Let a trajectory $(\psi_j)_0^\infty$ of F_a in W_s be given. The points $\chi_j = K(\psi_j) \in W$ form a trajectory of H since

$$\chi_{j+1} = K(\psi_{j+1}) = K\bigl(F_a(\psi_j)\bigr) = K\bigl(F_a\bigl(R(\chi_j)\bigr)\bigr) = H(\chi_j)$$

for each integer $j \geqslant 0$. Hence

$$\begin{aligned}\|\psi_j-\phi_0\|_{C^1} &= \big\|R(\chi_j)-R(0)\big\|_{C^1}\\ &\leqslant L_R\|\chi_j\|_{C^1}\\ &\leqslant L_R c_1^{-1}\|\chi_j\|_H\\ &\leqslant L_R c_1^{-1}\alpha^j\|\chi_0\|_H\\ &\leqslant L_R\frac{c_2}{c_1}\alpha^j\|\chi_0\|_{C^1}\\ &= L_R\frac{c_2}{c_1}\alpha^j\|P\|_{C^1}\|\psi_0-\phi_0\|_{C^1}.\end{aligned}$$

□

We want to show that the semiflow F maps a piece W^s of W_s close to ϕ_0 into W_s, in the sense that $F([0,\infty)\times W^s)\subset W_s$. The proof requires a quantitative version of continuous dependence on initial conditions. Notice that the proof of the latter employs the Lipschitz property (L) of the functional f.

PROPOSITION 3.5.3. *There exist an open neighbourhood* $X_{f,a}$ *of* ϕ_0 *in* X_f *and a constant* $c_a \geqslant 0$ *so that* $[0,a]\times X_{f,a}\subset\Omega$ *and*

$$\big\|F(t,\phi)-\phi_0\big\|_{C^1}\leqslant c_a\|\phi-\phi_0\|_{C^1}\quad \textit{for all } (t,\phi)\in[0,a]\times X_{f,a}.$$

PROOF. 1. Using continuity of the semiflow and compactness of the interval $[0,a]$ we find an open neighbourhood $X_{f,a}$ of the stationary point ϕ_0 in X_f so that $[0,a]\times X_{f,a}\subset\Omega$ and $F([0,a]\times X_{f,a})$ is contained in a neighbourhood of ϕ_0 in the domain U of f on which the Lipschitz estimate (L) holds.

2. Let $\xi=\phi_0(0)$, and let $\phi\in X_{f,a}$ be given. Set $x=x^\phi$. For $0\leqslant t\leqslant a$, we have

$$\begin{aligned}\big|x(t)-\xi\big| &= \left|x(0)-\xi+\int_0^t x'(s)\,\mathrm{d}s\right| = \left|x(0)-\xi+\int_0^t f(x_s)\,\mathrm{d}s\right|\\ &\leqslant \|x_0-\phi_0\|_C+L\int_0^t\|x_s-\phi_0\|_C\,\mathrm{d}s,\end{aligned}$$

as $f(\phi_0)=0$. For any $t\in[0,a]$ there exists $t_0\in[t-h,t]$ with $\|x_t-\phi_0\|_C=|x(t_0)-\xi|$. In case $t_0<0$ we obtain

$$\|x_t-\phi_0\|_C\leqslant\|x_0-\phi_0\|_C$$

while in case $t_0\geqslant 0$,

$$\begin{aligned}\|x_t-\phi_0\|_C &\leqslant \|x_0-\phi_0\|_C+L\int_0^{t_0}\|x_s-\phi_0\|_C\,\mathrm{d}s\\ &\leqslant \|x_0-\phi_0\|_C+L\int_0^t\|x_s-\phi_0\|_C\,\mathrm{d}s.\end{aligned}$$

In both cases,

$$\|x_t - \phi_0\|_C \leqslant \|x_0 - \phi_0\|_C + L\int_0^t \|x_s - \phi_0\|_C \, \mathrm{d}s.$$

Gronwall's lemma yields

$$\|F(t,\phi) - \phi_0\|_C \leqslant \|\phi - \phi_0\|_C \, \mathrm{e}^{Lt} \quad \text{on } [0,a] \times X_{f,a}.$$

Consequently, for all $(t,\phi) \in [0,a] \times X_{f,a}$,

$$\left|\left(x^\phi\right)'(t)\right| = \left|f\left(x_t^\phi\right) - f(\phi_0)\right| \leqslant L\left\|x_t^\phi - \phi_0\right\|_C \leqslant L\,\mathrm{e}^{Lt}\|\phi - \phi_0\|_C.$$

It follows that

$$\left\|\left(x_t^\phi\right)' - (\phi_0)'\right\|_C \leqslant L\,\mathrm{e}^{Lt}\|\phi - \phi_0\|_{C^1},$$

and finally

$$\left\|F(t,\phi) - \phi_0\right\|_{C^1} \leqslant (L+1)\mathrm{e}^{La}\|\phi - \phi_0\|_{C^1}$$

on $[0,a] \times X_{f,a}$. □

Now we can prove the desired invariance property of W_s with respect to the semiflow F, and an exponential estimate. Set

$$\gamma = -\frac{\log \alpha}{a};$$

then $0 < \beta < \gamma$.

PROPOSITION 3.5.4. *There exists an open neighbourhood W^s of ϕ_0 in W_s so that $[0,\infty) \times W^s \subset \Omega$, $F([0,\infty) \times W^s) \subset W_s$, and there is a constant $c_w \geqslant 0$ so that*

$$\left\|F(t,\psi) - \phi_0\right\|_{C^1} \leqslant c_w\,\mathrm{e}^{-\gamma t}\|\psi - \phi_0\|_{C^1} \quad \text{for all } \psi \in W^s,\ t \geqslant 0. \tag{3.5.1}$$

PROOF. 1. Set $V_N = R(N)$. Choose c_s according to Corollary 3.5.2(ii) and $X_{f,a}$ and c_a according to Proposition 3.5.3. It follows that there is an open neighbourhood W^s of ϕ_0 in $W_s \cap X_{f,a} \subset V_N \cap X_{f,a}$ so that

$$F_a\left(W^s\right) \subset W^s, \tag{3.5.2}$$

$$F\left([0,a] \times W^s\right) \subset V_N, \tag{3.5.3}$$

and

$$\left\{\chi \in Y\colon \|\chi\|_{C^1} \leqslant \|P\|_{C^1}\, c_a\, c_s \sup_{\eta \in W^s} \|\eta - \phi_0\|_{C^1}\right\} \subset N. \tag{3.5.4}$$

Using (3.5.2) and (3.5.3) and properties of the semiflow we get $[0,\infty) \times W^s \subset \Omega$ and $F([0,\infty) \times W^s) \subset V_N$.

2. Proof of $F([0,\infty) \times W^s) \subset W_s$. Let $t \geqslant 0$ and $\psi \in W^s$ be given. The assertion $\rho = F(t,\psi) \in W_s$ is equivalent to

$$K(\rho) \in K(W_s) = W. \tag{3.5.5}$$

By the remarks in part 1 the point ρ defines a trajectory $(\rho_j)_0^\infty$ of F_a in V_N, with $\rho_0 = \rho$, and the point $\psi \in W^s$ defines a trajectory $(\psi_j)_0^\infty$ of F_a in $W^s \subset V_N$, with $\psi_0 = \psi$. The points $\chi_j = K(\rho_j)$ form a trajectory of H in N since

$$\chi_{j+1} = K(\rho_{j+1}) = K\bigl(F_a(\rho_j)\bigr) = K\bigl(F_a\bigl(R(\chi_j)\bigr)\bigr) = H(\chi_j)$$

for all integers $j \geqslant 0$. Proposition 3.5.1(iv) shows that (3.5.5) follows from

$$\lambda^{-j}\chi_j \in N \quad \text{for all integers } j \geqslant 0. \tag{3.5.6}$$

Proof of (3.5.6). Let $j \in \mathbb{N}_0$, $k \in \mathbb{N}_0$, $ka \leqslant t < (k+1)a$. Then

$$\begin{aligned}
\|\chi_j\|_{C^1} &= \bigl\|K(\rho_j)\bigr\|_{C^1} \\
&= \bigl\|P(\rho_j - \phi_0)\bigr\|_{C^1} \\
&\leqslant \|P\|_{C^1}\|\rho_j - \phi_0\|_{C^1} \\
&= \|P\|_{C^1}\bigl\|F(ja,\rho) - \phi_0\bigr\|_{C^1} \\
&= \|P\|_{C^1}\bigl\|F\bigl(t-ka, F\bigl((j+k)a,\psi\bigr)\bigr) - \phi_0\bigr\|_{C^1} \\
&\leqslant \|P\|_{C^1} c_a \|\psi_{j+k} - \phi_0\|_{C^1} \\
&\leqslant \|P\|_{C^1} c_a c_s \alpha^{j+k}\|\psi - \phi_0\|_{C^1},
\end{aligned}$$

hence

$$\bigl\|\lambda^{-j}\chi_j\bigr\|_{C^1} \leqslant \|P\|_{C^1} c_a c_s \cdot 1 \cdot \sup_{\eta \in W^s} \|\eta - \phi_0\|_{C^1},$$

which yields

$$\lambda^{-j}\chi_j \in N,$$

according to (3.5.4).

3. Proof of (3.5.1). Let $\psi \in W^s$, $t \geqslant 0$, $j \in \mathbb{N}_0$, $ja \leqslant t < (j+1)a$. Then

$$\begin{aligned}
\bigl\|F(t,\psi) - \phi_0\bigr\|_{C^1} &= \bigl\|F\bigl(t - ja, F(ja,\psi)\bigr) - \phi_0\bigr\|_{C^1} \\
&\leqslant c_a\bigl\|F(ja,\psi) - \phi_0\bigr\|_{C^1}
\end{aligned}$$

$$
\begin{aligned}
&\leqslant c_a c_s \alpha^j \|\psi - \phi_0\|_{C^1} \\
&= c_a c_s \mathrm{e}^{j \log \alpha} \|\psi - \phi_0\|_{C^1} \\
&= c_a c_s \mathrm{e}^{(t \log \alpha)/a} \mathrm{e}^{(j - t/a) \log \alpha} \|\psi - \phi_0\|_{C^1} \\
&\leqslant c_a c_s \mathrm{e}^{(t \log \alpha)/a} \alpha^{-1} \|\psi - \phi_0\|_{C^1}. \qquad \square
\end{aligned}
$$

The C^1-submanifold W^s of X_f is the local stable manifold of F at ϕ_0. It is locally positively invariant under F, with tangent space

$$T_{\phi_0} W^s = C_s \cap T_{\phi_0} X_f,$$

and it has the following uniqueness property: There exists a constant $c > 0$ so that all initial data $\psi \in X_f$ with $[0, \infty) \times \{\psi\} \subset \Omega$ and

$$\mathrm{e}^{\beta t} \left\| F(t, \psi) - \phi_0 \right\|_{C^1} < c \quad \text{for all } t \geqslant 0$$

belong to W^s. This property is easily established by means of estimates as in the preceding proofs.

We said already that analogously to the approach to local *stable* manifolds just presented one obtains continuously differentiable local *unstable* manifolds for the semiflow from local unstable manifolds of the maps F_a, $a > 0$.

Local *unstable* manifolds for certain classes of differential equations with state-dependent delay were also obtained in earlier work, by Krishnan [126,127] and more generally in [129]. The proofs in [126,127] and [129] proceed without knowledge of a semiflow and use the heuristic approach with the auxiliary linear equation mentioned in Section 3.4. It is remarkable that in [129] higher order differentiability of local unstable manifolds is achieved.

Related to work on local invariant manifolds is a result of Arino and Sanchez [10] about saddle point behaviour of solutions close to a stationary point which is hyperbolic, i.e., there is no spectrum of the generator G_e on the imaginary axis. Also in [10] no semiflow is available, and the auxiliary linear equation is used.

3.6. *The principle of linearized stability*

For $f : U \to \mathbb{R}^n$, $U \subset C^1$ open, with property (S) and the associated semiflow F of Theorem 3.2.1 the results of Section 3.4 and Proposition 3.5.4 yield the following Principle of Linearized Stability.

THEOREM 3.6.1. *If all eigenvalues of G_e have negative real part then ϕ_0 is exponentially asymptotically stable for the semiflow F.*

For applications, recall that the eigenvalues of G_e and their multiplicities are given by the familiar transcendental characteristic equation which is obtained from the Ansatz $v(t) = \mathrm{e}^{\lambda t} c$ for a solution to the equation

$$v'(t) = \mathrm{D}_e f(\phi_0) v_t.$$

Earlier Principles of Linearized Stability, for certain classes of differential equations with state-dependent delay, are due to Cooke and Huang [48] and to Hartung and Turi [105, 108]. The proofs employ the heuristic approach described in Section 3.4. Related is work by Hartung [101] on exponential stability of periodic solutions to nonautonomous, periodic differential equations with state-dependent delay, and a result by Győri and Hartung [92] who derive exponential stability of the zero solution of the nonautonomous equation

$$x'(t) = a(t) x\big(t - r\big(t, x(t)\big)\big)$$

from exponential stability of the zero solution to the linear nonautonomous RFDE

$$y'(t) = a(t) y\big(t - r(t, 0)\big).$$

4. Center manifolds

4.1. *Preliminaries*

Assume $f : U \to \mathbb{R}^n$, $U \subset C^1$ open, with property (S) of Section 3, and define X_f as in Section 3. By Theorem 3.2.1, in case $X_f \neq \emptyset$ the solutions of the equation

$$x'(t) = f(x_t) \tag{1.0.1}$$

with initial function $x_0 = \phi \in X_f$ define a semiflow $F : \Omega \to X_f$. Assume that $0 \in U$ and 0 is a stationary point of F. Define $L = \mathrm{D} f(0)$, $L_e = \mathrm{D}_e f(0)$ and

$$r : U \ni \phi \mapsto f(\phi) - L\phi \in \mathbb{R}^n.$$

Clearly, r also satisfies (S), and $r(0) = 0$, $\mathrm{D}r(0) = 0$. Then (1.0.1) is equivalent to

$$x'(t) = L x_t + r(x_t). \tag{4.1.1}$$

The solutions of the IVP

$$y'(t) = L_e y_t, \quad y_0 = \phi \in C$$

define the strongly continuous semigroup $(T_e(t))_{t \geqslant 0}$ on C with generator $G_e : \mathrm{dom}(G_e) \to C$, $\mathrm{dom}(G_e) = \{\phi \in C^1 \colon \phi'(0) = L_e(\phi)\}$, $G_e \phi = \phi'$. The realified generalized eigenspaces of G_e given by the eigenvalues with negative, zero and positive real part are the stable C_s, center C_c and unstable C_u spaces, respectively. We have the decomposition

$$C = C_s \oplus C_c \oplus C_u,$$

C_s is infinite dimensional, C_c and C_u are finite dimensional, $C_c \subset \mathrm{dom}(G_e)$, $C_u \subset \mathrm{dom}(G_e)$. The set $C_s^1 = C_s \cap C^1$ is a closed subset of C^1. Hence we get the decomposition

$$C^1 = C_s^1 \oplus C_c \oplus C_u \tag{4.1.2}$$

of C^1.

The derivatives $D_2F(t, 0)$, $t \geqslant 0$, form the strongly continuous semigroup $T(t)$, $t \geqslant 0$, on $T_0X_f = \mathrm{dom}(G_e)$ with generator G. The stable, center and unstable subspaces of G are $C_s \cap \mathrm{dom}(G_e) = C_s^1 \cap \mathrm{dom}(G_e)$, C_c and C_u, respectively, and

$$T_0X_f = \mathrm{dom}(G_e) = \bigl(C_s^1 \cap \mathrm{dom}(G_e)\bigr) \oplus C_c \oplus C_u.$$

In the sequel we assume

$$\dim C_c \geqslant 1.$$

The main result of this section guarantees the existence of a Lipschitz smooth (local) center manifold of F at the stationary point 0.

THEOREM 4.1.1. *There exist open neighbourhoods $C_{c,0}$ of* 0 *in C_c and $C^1_{su,0}$ in $C_s^1 \oplus C_u$ with $N = C_{c,0} + C^1_{su,0} \subset U$, a Lipschitz continuous map $w_c : C_{c,0} \to C^1_{su,0}$ such that* $w_c(0) = 0$ *and for the graph*

$$W_c = \{\phi + w_c(\phi) \colon \phi \in C_{c,0}\}$$

of w_c the following holds.

(i) *$W_c \subset X_f$, and W_c is a* $\dim C_c$*-dimensional Lipschitz smooth submanifold of X_f.*

(ii) *If $x : \mathbb{R} \to \mathbb{R}^n$ is a continuously differentiable solution of* (1.0.1) *on* $\mathbb{R}$ *with $x_t \in N$ for all $t \in \mathbb{R}$, then $x_t \in W_c$ for all $t \in \mathbb{R}$.*

(iii) *W_c is locally positively invariant with respect to the semiflow F, i.e., if $\phi \in W_c$ and $\alpha > 0$ such that $F(t, \phi)$ is defined for all $t \in [0, \alpha)$, and $F(t, \phi) \in N$ for all $t \in [0, \alpha)$, then $F(t, \phi) \in W_c$ for all $t \in [0, \alpha)$.*

The proof will be given in Section 4.3. We follow the approach of [54] by applying the Lyapunov–Perron method. The variation-of-constants formula is from [54] which requires dual spaces and adjoint operators. Other forms of the variation-of-constants formula, obtained, e.g., via integrated semigroups or extrapolation theory, could also be used. The existence of a global center manifold for a modified version of Eq. (4.1.1) is formulated as a fixed point problem with a parameter. However, as the right-hand side of (4.1.1) has smoothness properties only in the space C^1, the space, where we look for fixed points, should contain smoother functions than the corresponding space in [54]. This is why the proof is not a straightforward application of the technique of [54]. The C^1-smoothness of W_c also holds under the hypotheses of Theorem 4.1.1. A proof can be found in [131].

4.2. *The linear inhomogeneous equation*

Let $|\cdot|$ be a norm in $\mathbb{R}^n$. The spaces C, C^1 and their norms are defined as in Section 1. Let $L^\infty(-h,0;\mathbb{R}^n)$ denote the Banach space of measurable and essentially bounded functions from $(-h,0)$ into $\mathbb{R}^n$ equipped with the essential least upper bound norm $\|\cdot\|_\infty$.

We denote dual spaces and adjoint operators by an asterisk $*$ in the sequel. The elements $\phi^\odot$ of C^* for which the curve

$$[0,\infty)\ni t\mapsto T_e^*(t)\phi^\odot\in C^*$$

is continuous form a closed subspace $C^\odot$ (of C^*) which is positively invariant under $T_e^*(t)$, $t\geqslant 0$. The operators

$$T_e^\odot(t): C^\odot\ni\phi^\odot\mapsto T_e^*(t)\phi^\odot\in C^\odot,\quad t\geqslant 0,$$

constitute a strongly continuous semigroup on $C^\odot$. Similarly, we can introduce the dual space $C^{\odot*}$ and the semigroup of adjoint operators $T_e^{\odot*}(t)$, $t\geqslant 0$, which is strongly continuous on $C^{\odot\odot}$. There is an isometric isomorphism between $\mathbb{R}^n\times L^\infty(-h,0;\mathbb{R}^n)$ equipped with the norm $\|(\alpha,\phi)\|=\max\{|\alpha|,\|\phi\|_\infty\}$ and $C^{\odot*}$. We will identify $C^{\odot*}$ with $\mathbb{R}^n\times L^\infty(-h,0;\mathbb{R}^n)$ and omit the isomorphism. The original state space is sun-reflexive in the sense that, for the norm-preserving linear map $j: C\to C^{\odot*}$ given by $j(\phi)=(\phi(0),\phi)$, we have $j(C)=C^{\odot\odot}$. We also omit the embedding operator j and identify C and $C^{\odot\odot}$. All of these results as well as the decomposition of $C^{\odot*}$ and the variation-of-constants formula can be found in [54].

Let $Y^{\odot*}$ denote the subspace $\mathbb{R}^n\times\{0\}$ of $C^{\odot*}$. For the kth unit vector e_k in $\mathbb{R}^n$ set $r_k^{\odot*}=(e_k,0)\in Y^{\odot*}$. Let $l:\mathbb{R}^n\to Y^{\odot*}$ be the linear map given by $l(e_k)=r_k^{\odot*}$, $k\in\{1,2,\dots,n\}$. Then l has an inverse l^{-1}, and $\|l\|=\|l^{-1}\|=1$.

Let $G_e^{\odot*}$ denote the generator of $T_e^{\odot*}$. For the spectra $\sigma(G_e)$ and $\sigma(G_e^{\odot*})$ we have $\sigma(G_e)=\sigma(G_e^{\odot*})$. Recall that we assumed

$$\sigma(G_e)\cap\mathrm{i}\mathbb{R}\neq\emptyset.$$

Then $C^{\odot*}$ can be decomposed as

$$C^{\odot*}=C_s^{\odot*}\oplus C_c\oplus C_u,\tag{4.2.1}$$

where $C_s^{\odot*}$, C_c, C_u are closed subspaces of $C^{\odot*}$, C_c and C_u are contained in C^1, $1\leqslant\dim C_c<\infty$, $\dim C_u<\infty$. The subspaces $C_s^{\odot*}$, C_c and C_u are invariant under $T_e^{\odot*}(t)$,

$t \geqslant 0$, and $T_e(t)$ can be extended to a one-parameter group on both C_c and C_u. There exist real numbers $K \geqslant 1$, $a < 0$, $b > 0$ and $\epsilon > 0$ with $\epsilon < \min\{-a, b\}$ such that

$$\begin{aligned} \|T_e(t)\phi\| &\leqslant K\mathrm{e}^{bt}\|\phi\|, && t \leqslant 0,\ \phi \in C_u, \\ \|T_e(t)\phi\| &\leqslant K\mathrm{e}^{\epsilon|t|}\|\phi\|, && t \in \mathbb{R},\ \phi \in C_c, \\ \|T_e^{\odot *}(t)\phi\| &\leqslant K\mathrm{e}^{at}\|\phi\|, && t \geqslant 0,\ \phi \in C_s^{\odot *}. \end{aligned} \tag{4.2.2}$$

Using the identification of C and $C^{\odot\odot}$, we obtain $C_s^1 = C^1 \cap C_s^{\odot *}$. The decompositions (4.1.2) and (4.2.1) define the projection operators P_s, P_c, P_u and $P_s^{\odot *}$, $P_c^{\odot *}$, $P_u^{\odot *}$ with ranges C_s^1, C_c, C_u and $C_s^{\odot *}$, C_c, C_u, respectively.

We need a variation-of-constants formula for solutions of

$$x'(t) = L_e x_t + q(t) \tag{4.2.3}$$

with a continuous function $q : \mathbb{R} \to \mathbb{R}^n$.

If c, d are reals with $c \leqslant d$, and $w : [c, d] \to C^{\odot *}$ is continuous, then the weak-star integral

$$\int_c^d T_e^{\odot *}(d - \tau)w(\tau)\,\mathrm{d}\tau \in C^{\odot *}$$

is defined by

$$\left(\int_c^d T_e^{\odot *}(d - \tau)w(\tau)\,\mathrm{d}\tau\right)(\phi^{\odot}) = \int_c^d T_e^{\odot *}(d - \tau)w(\tau)(\phi^{\odot})\,\mathrm{d}\tau$$

for all $\phi^{\odot} \in C^{\odot}$.

If $I \subset \mathbb{R}$ is an interval, $q : I \to \mathbb{R}^n$ is continuous and $x : I + [-h, 0] \to \mathbb{R}^n$ is a solution of (4.2.3) on I, then the curve $u : I \ni t \mapsto x_t \in C$ satisfies the integral equation

$$u(t) = T_e(t - s)u(s) + \int_s^t T_e^{\odot *}(t - \tau)Q(\tau)\,\mathrm{d}\tau, \quad t, s \in I,\ s \leqslant t, \tag{4.2.4}$$

with $Q(t) = l(q(t))$, $t \in I$. Moreover, if $Q : I \to Y^{\odot *}$ is continuous, and $u : I \to C$ satisfies (4.2.4), then there is a continuous function $x : I + [-h, 0] \to \mathbb{R}^n$ such that $x_t = u(t)$ for all $t \in I$, and x satisfies (4.2.3) with $q(t) = l^{-1}(Q(t))$, $t \in I$. So, there is a one-to-one correspondence between the solutions of (4.2.3) and (4.2.4).

For a Banach space B with norm $\|\cdot\|$ and a real $\eta \geqslant 0$, we define the Banach space

$$C_\eta(\mathbb{R}, B) = \left\{b \in C(\mathbb{R}, B) \colon \sup_{t \in \mathbb{R}} \mathrm{e}^{-\eta|t|}\|b(t)\| < \infty\right\}$$

with norm

$$\|b\|_{C_\eta^0(\mathbb{R}, B)} = \sup_{t \in \mathbb{R}} \mathrm{e}^{-\eta|t|}\|b(t)\|.$$

For $\eta \geqslant 0$, we introduce the notation

$$Y_\eta = C_\eta\big(\mathbb{R}, Y^{\odot *}\big), \quad C_\eta^0 = C_\eta(\mathbb{R}, C), \quad C_\eta^1 = C_\eta\big(\mathbb{R}, C^1\big).$$

We need the following smoothing property of Eq. (4.2.4).

PROPOSITION 4.2.1. *Let $\eta \geqslant 0$, $Q \in Y_\eta$, $u \in C_\eta^0$, and assume that u satisfies*

$$u(t) = T_e(t-s)u(s) + \int_s^t T_e^{\odot *}(t-\tau)Q(\tau)\,\mathrm{d}\tau, \quad -\infty < s \leqslant t < \infty.$$

Then $u \in C_\eta^1$ and

$$\|u\|_{C_\eta^1} \leqslant \big(1 + \mathrm{e}^{\eta h}\|L_e\|\big)\|u\|_{C_\eta^0} + \mathrm{e}^{\eta h}\|Q\|_{Y_\eta}.$$

PROOF. Define $q : \mathbb{R} \to \mathbb{R}^n$ by $q(t) = l^{-1}(Q(t))$, $t \in \mathbb{R}$. Then $q \in C_\eta(\mathbb{R}, \mathbb{R}^n)$, and

$$\|q\|_{C_\eta(\mathbb{R},\mathbb{R}^n)} = \|Q\|_{Y_\eta}.$$

The function $x : \mathbb{R} \to \mathbb{R}^n$, given by $x(t) = u(t)(0)$, satisfies $x_t = u(t)$, $t \in \mathbb{R}$, and Eq. (4.2.3) holds for all $t \in \mathbb{R}$. Then x is C^1-smooth, $x_t \in C^1$ for all $t \in \mathbb{R}$, and the mapping $\mathbb{R} \ni t \mapsto x_t \in C^1$ is continuous. Moreover, for all $t \in \mathbb{R}$,

$$\begin{aligned}
\big|x'(t)\big| &\leqslant \|L_e\|\|x_t\|_C + \big|q(t)\big| \\
&= \|L_e\|\big\|u(t)\big\|_C + \big\|Q(t)\big\|_{Y^{\odot *}} \\
&\leqslant \mathrm{e}^{\eta|t|}\big(\|L_e\|\|u\|_{C_\eta^0} + \|Q\|_{Y_\eta}\big).
\end{aligned}$$

Hence

$$\begin{aligned}
\sup_{t\in\mathbb{R}} \mathrm{e}^{-\eta|t|}\big\|x_t'\big\|_C &= \sup_{t\in\mathbb{R}} \mathrm{e}^{-\eta|t|} \sup_{-h\leqslant s\leqslant 0} \big|x'(t+s)\big| \\
&\leqslant \big(\|L_e\|\|u\|_{C_\eta^0} + \|Q\|_{Y_\eta}\big) \sup_{t\in\mathbb{R}} \mathrm{e}^{-\eta|t|} \sup_{-h\leqslant s\leqslant 0} \mathrm{e}^{\eta|t+s|} \\
&\leqslant \mathrm{e}^{\eta h}\big(\|L_e\|\|u\|_{C_\eta^0} + \|Q\|_{Y_\eta}\big).
\end{aligned}$$

Therefore, $u \in C_\eta^1$, and

$$\begin{aligned}
\|u\|_{C_\eta^1} &= \sup_{t\in\mathbb{R}} \mathrm{e}^{-\eta|t|}\|x_t\|_{C^1} = \sup_{t\in\mathbb{R}} \mathrm{e}^{-\eta|t|}\big(\|x_t\|_C + \big\|x_t'\big\|_C\big) \\
&\leqslant \|u\|_{C_\eta^0} + \mathrm{e}^{\eta h}\|L_e\|\|u\|_{C_\eta^0} + \mathrm{e}^{\eta h}\|Q\|_{Y_\eta}.
\end{aligned}$$

□

For a given $Q:\mathbb{R}\to Y^{\odot *}$ we (formally) define

$$(\mathcal{K}Q)(t)=\int_0^t T_e^{\odot *}(t-\tau)P_c^{\odot *}Q(\tau)\,\mathrm{d}\tau+\int_\infty^t T_e^{\odot *}(t-\tau)P_u^{\odot *}Q(\tau)\,\mathrm{d}\tau$$
$$+\int_{-\infty}^t T_e^{\odot *}(t-\tau)P_s^{\odot *}Q(\tau)\,\mathrm{d}\tau.$$

PROPOSITION 4.2.2. *Assume* $\eta\in(\epsilon,\min\{-a,b\})$. *Then the mapping*

$$\mathcal{K}_\eta : Y_\eta \ni Q\mapsto \mathcal{K}Q\in C_\eta^1$$

is linear bounded with norm

$$\|\mathcal{K}_\eta\|\leqslant K\bigl(1+\mathrm{e}^{\eta h}\|L_e\|\bigr)\left(\frac{1}{\eta-\epsilon}+\frac{1}{-a-\eta}+\frac{1}{b-\eta}\right)+\mathrm{e}^{\eta h}.$$

If $Q\in Y_\eta$ *then* $u=\mathcal{K}Q$ *is the unique solution of*

$$u(t)=T_e(t-s)u(s)+\int_s^t T_e^{\odot *}(t-\tau)Q(\tau)\,\mathrm{d}\tau,\quad -\infty<s\leqslant t<\infty, \tag{4.2.5}$$

in C_η^1 *with* $P_c^{\odot *}u(0)=0$.

PROOF. Lemma IX.3.2 of [54] shows that $\mathcal{K}$ as a mapping from Y_η into C_η^0 is linear bounded such that its norm is bounded by

$$K\left(\frac{1}{\eta-\epsilon}+\frac{1}{-a-\eta}+\frac{1}{b-\eta}\right),$$

moreover $u=\mathcal{K}Q$ with $Q\in Y_\eta$ is the unique solution of (4.2.5) with $P_c^{\odot *}u(0)=0$. Hence Proposition 4.2.1 yields the boundedness of $\mathcal{K}_\eta$ with the stated bound for the norm. □

4.3. *Construction of a center manifold*

Now we prove Theorem 4.1.1.

As $\dim C_c<\infty$, there is a norm $|\cdot|_c$ on C_c which is C^∞-smooth on $C_c\setminus\{0\}$. Then

$$|\phi|_1=\max\bigl\{|P_c\phi|_c,\ \bigl\|(\mathrm{id}_{C^1}-P_c)\phi\bigr\|_{C^1}\bigr\},\quad \phi\in C^1,$$

defines the new norm $|\cdot|_1$ on C^1 which is equivalent to $\|\cdot\|_{C^1}$.

Let $\rho:\mathbb{R}\to\mathbb{R}$ be a C^∞-smooth function so that $\rho(t)=1$ for $t\leqslant 1$, $\rho(t)=0$ for $t\geqslant 2$, and $\rho(t)\in(0,1)$ for $t\in(1,2)$.

Define

$$\hat{r}(\phi) = \begin{cases} r(\phi), & \text{if } \phi \in U; \\ 0, & \text{if } \phi \notin U. \end{cases}$$

For any $\delta > 0$, let

$$r_\delta(\phi) = \hat{r}(\phi)\rho\left(\frac{|P_c\phi|_c}{\delta}\right)\rho\left(\frac{|(\mathrm{id}_{C^1} - P_c)\phi|_1}{\delta}\right), \quad \phi \in C^1.$$

For $\gamma > 0$ set $B_\gamma(C^1) = \{\phi \in C^1\colon\ |\phi|_1 < \gamma\}$.

Choose $\delta_0 > 0$ so that

$$B_{2\delta_0}\bigl(C^1\bigr) \subset U,$$

and $r|_{B_{2\delta_0}(C^1)}$, $\mathrm{D}r|_{B_{2\delta_0}(C^1)}$ are bounded. Then, for any $\delta \in (0, \delta_0)$

$$r_\delta|_{\{\phi\in C^1\colon\ |(\mathrm{id}_{C^1} - P_c)\phi|_1 < \delta\}}(\phi) = \hat{r}(\phi)\rho\left(\frac{|P_c\phi|_c}{\delta}\right), \quad \phi \in C^1,$$

and $r_\delta|_{\{\phi\in C^1\colon\ |(\mathrm{id}_{C^1} - P_c)\phi|_1 < \delta\}}$ is a bounded and C^1-smooth function with bounded derivative.

There exist $\delta_1 \in (0, \delta_0)$ and a nondecreasing function $\mu\colon [0, \delta_1] \to [0, 1]$ such that μ is continuous at 0, $\mu(0) = 0$, and for all $\delta \in (0, \delta_1]$ and for all $\phi, \psi \in C^1$

$$\begin{aligned} &\bigl|r_\delta(\phi)\bigr| \leqslant \delta\mu(\delta), \\ &\bigl|r_\delta(\phi) - r_\delta(\psi)\bigr| \leqslant \mu(\delta)\|\phi - \psi\|_{C^1}. \end{aligned} \tag{4.3.1}$$

For a proof of completely analogous estimates see, e.g., Proposition II.2 in [133].

For $\delta \in (0, \delta_1]$ we consider the modified equations

$$x'(t) = Lx_t + r_\delta(x_t), \quad t \in \mathbb{R}, \tag{4.3.2}$$

and

$$u(t) = T_e(t - s) + \int_s^t T_e^{\odot *}(t - \tau)l\bigl(r_\delta\bigl(u(\tau)\bigr)\bigr)\,\mathrm{d}\tau, \quad -\infty < s \leqslant t < \infty. \tag{4.3.3}$$

These equations are equivalent in the following sense: If $x\colon \mathbb{R} \to \mathbb{R}^n$ is C^1-smooth and is a solution of Eq. (4.3.2), then $u\colon \mathbb{R} \ni t \mapsto x_t \in C^1$ is a solution of Eq. (4.3.3), and conversely, a continuous $u\colon \mathbb{R} \to C^1$ satisfying (4.3.3) defines a C^1-smooth solution of (4.3.2) by $x(t) = u(t)(0)$, $t \in \mathbb{R}$.

Now we fix the reals $\eta \in (\epsilon, \min\{-a, b\})$ and $\delta \in (0, \delta_1)$ such that

$$\|\mathcal{K}_\eta\| \mu(\delta) < \frac{1}{2}. \tag{4.3.4}$$

Let the substitution operator

$$R : (C^1)^{\mathbb{R}} \to (Y^{\odot *})^{\mathbb{R}}$$

of the map $C^1 \ni \phi \mapsto l(r_\delta(\phi)) \in Y^{\odot *}$ be given by

$$R(u)(t) = l\big(r_\delta\big(u(t)\big)\big).$$

Inequalities (4.3.1) and $\|l\| = 1$ yield that

$$R\big(C^1_\eta\big) \subset Y_\eta,$$

and for the induced map

$$R_{\delta\eta} : C^1_\eta \to Y_\eta,$$

the inequalities

$$\big\| R_{\delta\eta}(u) \big\|_{Y_\eta} \leqslant \delta\mu(\delta), \quad u \in C^1_\eta,$$

and

$$\big\| R_{\delta\eta}(u) - R_{\delta\eta}(v) \big\|_{Y_\eta} \leqslant \mu(\delta) \|u - v\|_{C^1_\eta}, \quad u, v \in C^1_\eta, \tag{4.3.5}$$

hold.

Let the mapping $S : C_c \to C^1_\eta$ be given by $(S\phi)(t) = T_e(t)\phi$, $\phi \in C_c$, $t \in \mathbb{R}$. For all $\phi \in C_c$ we have $\|T_e(t)\phi\|_{C^1} = \|T_e(t)\phi\|_C + \|\frac{\mathrm{d}}{\mathrm{d}t}(T_e(t)\phi)\|_C$ and $\frac{\mathrm{d}}{\mathrm{d}t}(T_e(t)\phi) = T_e(t)G_e\phi = T_e(t)\phi'$. Therefore, by applying the second inequality in (4.2.2) and $\eta > \epsilon$, we find

$$\begin{aligned} \|S\phi\|_{C^1_\eta} &= \sup_{t \in \mathbb{R}} \mathrm{e}^{-\eta|t|} \big(\big\| T_e(t)\phi \big\|_C + \big\| T_e(t)\phi' \big\|_C \big) \\ &\leqslant K \big(\|\phi\|_C + \big\|\phi'\big\|_C \big) \\ &\leqslant K \|\phi\|_{C^1}. \end{aligned} \tag{4.3.6}$$

Define the mapping

$$\mathcal{G} : C^1_\eta \times C_c \to C^1_\eta$$

by

$$\mathcal{G}(u, \phi) = S\phi + \mathcal{K}_\eta \circ R_{\delta\eta}(u), \quad u \in C^1_\eta,\ \phi \in C_c.$$

For all $u, v \in C^1_\eta$ and $\phi \in C_c$, (4.3.4) and (4.3.5) yield

$$\begin{aligned}\left\|\mathcal{G}(u,\phi) - \mathcal{G}(v,\phi)\right\|_{C^1_\eta} &\leqslant \|\mathcal{K}_\eta\| \left\|R_{\delta\eta}(u) - R_{\delta\eta}(v)\right\|_{Y_\eta} \\ &\leqslant \|\mathcal{K}_\eta\| \mu(\delta) \|u - v\|_{C^1_\eta} \\ &\leqslant \frac{1}{2} \|u - v\|_{C^1_\eta}.\end{aligned}$$

If $\gamma > 0$ and $\phi \in C_c$ with $\|\phi\|_{C^1} \leqslant \gamma/(2K)$, and $u \in \overline{B_\gamma(C^1_\eta)}$, then, by using (4.3.4), (4.3.5) and (4.3.6),

$$\begin{aligned}\left\|\mathcal{G}(u,\phi)\right\|_{C^1_\eta} &\leqslant K\|\phi\|_{C^1} + \|\mathcal{K}_\eta\| \mu(\delta) \|u\|_{C^1_\eta} \\ &\leqslant \frac{\gamma}{2} + \frac{\gamma}{2} = \gamma.\end{aligned}$$

Therefore, $\mathcal{G}(\cdot,\phi)$ maps $\overline{B_\gamma(C^1_\eta)}$ into itself provided $\gamma \geqslant 2K\|\phi\|_{C^1}$. In addition, $\mathcal{G}(\cdot,\phi)$ is Lipschitz continuous with Lipschitz constant $1/2$.

Consequently, there is a map

$$u^* : C_c \to C^1_\eta$$

such that, for each $\phi \in C_c$, $u = u^*(\phi)$ is the unique solution in C^1_η of the equation

$$u = \mathcal{G}(u,\phi).$$

The mapping u^* is globally Lipschitz continuous since

$$\left\|u^*(\phi) - u^*(\psi)\right\|_{C^1_\eta} \leqslant K\|\phi - \psi\|_{C^1} + \frac{1}{2}\left\|u^*(\phi) - u^*(\psi)\right\|_{C^1_\eta},$$

yielding

$$\left\|u^*(\phi) - u^*(\psi)\right\|_{C^1_\eta} \leqslant 2K\|\phi - \psi\|_{C^1}$$

for all $\phi, \psi \in C_c$.

The set

$$W = \left\{u^*(\phi)(0) \colon \phi \in C_c\right\}$$

is called the global center manifold of Eq. (4.3.2) at the stationary point 0.

Setting

$$w : C_c \ni \phi \mapsto (\mathrm{id}_{C^1} - P_c)u^*(\phi)(0) \in C^1_s \oplus C_u,$$

we get the graph representation

$$W = \{\phi + w(\phi) \colon \phi \in C_c\}$$

for W.

For all $\phi \in C_c$ we have

$$\begin{aligned} |w(\phi)|_1 &= \|w(\phi)\|_{C^1} = \|(\mathrm{id}_{C^1} - P_c)u^*(\phi)(0)\|_{C^1} \\ &= \|\mathcal{K}_\eta(R_{\delta\eta}(u^*(\phi)))(0)\|_{C^1} \leqslant \|\mathcal{K}_\eta(R_{\delta\eta}(u^*(\phi)))\|_{C^1_\eta} \\ &\leqslant \|\mathcal{K}_\eta\| \|R_{\delta\eta}(u^*(\phi))\|_{Y_\eta} \\ &\leqslant \|\mathcal{K}_\eta\| \delta\mu(\delta) < \delta. \end{aligned}$$

An important consequence is that

$$W \subset \{\phi \in C^1 \colon |(\mathrm{id}_{C^1} - P_c)\phi|_1 < \delta\},$$

that is, W is contained in the δ-neighbourhood of C_c, where r_δ is C^1-smooth with bounded derivative. This fact is essential in the proof of the C^1-smoothness of the center manifold.

Setting

$$\begin{aligned} &C_{c,0} = \{\phi \in C_c \colon |\phi|_1 < \delta\}, \\ &C^1_{su,0} = \{\phi \in C^1_s \oplus C_u \colon |\phi|_1 < \delta\}, \\ &N = C_{c,0} + C^1_{su,0} = \{\phi \in C^1 \colon |\phi|_1 < \delta\}, \\ &w_c = w|_{C_{c,0}}, \\ &W_c = \{\phi + w_c(\phi) \colon \phi \in C_{c,0}\}, \end{aligned}$$

we obtain that $w_c(C_{c,0}) \subset C^1_{su,0}$ and w_c is Lipschitz continuous. As $\mathcal{G}(0,0) = 0$, it follows that $u^*(0) = 0$, and consequently $w_c(0) = 0$.

Let $v \in C^1_\eta$ be a solution of Eq. (4.3.3). Define $z : \mathbb{R} \to C^1$ by

$$z(t) = v(t) - T_e(t)P_c v(0), \quad t \in \mathbb{R}.$$

Obviously, $v \in C^1_\eta$ implies $z \in C^1_\eta$. Moreover,

$$z(t) = T_e(t-s)z(s) + \int_s^t T_e^{\odot *}(t-\tau) l(r_\delta(v(\tau)))\, \mathrm{d}\tau, \quad -\infty < s \leqslant t < \infty.$$

As $P_c z(0) = 0$ and $v \in C^1_\eta$, Proposition 4.2.2 yields

$$z = \mathcal{K}_\eta(R_{\delta\eta}(v)).$$

Therefore

$$v = S\big(P_c v(0)\big) + \mathcal{K}_\eta\big(R_{\delta\eta}(v)\big),$$

and

$$v(0) = u^*\big(P_c v(0)\big) \in W^c.$$

For any $t \in \mathbb{R}$ and $\hat{v} : \mathbb{R} \ni s \mapsto v(t+s) \in C^1$, it is clear that $\hat{v} \in C^1_\eta$, and $\hat{v}$ is also a solution of Eq. (4.3.3). Therefore, $v(t) = \hat{v}(0) \in W$ follows for all $t \in \mathbb{R}$. Consequently, for each $v \in C^1_\eta$ satisfying Eq. (4.3.3), $v(t) \in W$ holds for all $t \in \mathbb{R}$.

If $x : \mathbb{R} \to \mathbb{R}^n$ is a solution of Eq. (1.0.1) with $x_t \in N$ for all $t \in \mathbb{R}$, then (4.3.2) also holds, and $u(t) = x_t$, $t \in \mathbb{R}$, satisfies Eq. (4.3.3) since $r|_N = r_\delta|_N$, and $u \in C^1_\eta$. Thus, $x_t \in W$, $t \in \mathbb{R}$. This proves (ii) of Theorem 4.1.1.

In order to show (iii) in Theorem 4.1.1, let $\phi \in W_c$. Then $u^*(P_c\phi) \in C^1_\eta$, and $u^*(P_c\phi)(t) \in W$ for all $t \in \mathbb{R}$. Let $\beta \in (0, \infty]$ be maximal so that

$$u^*(P_c\phi)(t) \in N \quad \text{for all } t \in [0, \beta),$$

that is,

$$u^*(P_c\phi)(t) \in W_c \quad \text{for all } t \in [0, \beta).$$

Then there exists a C^1-smooth function $y : [-h, \beta) \to \mathbb{R}^n$ so that $y_t = u^*(P_c\phi)(t)$, $t \in [0, \beta)$, and

$$\begin{cases} y'(t) = Ly_t + r(y_t), & 0 < t < \beta, \\ y_0 = \phi. \end{cases}$$

If $x^\phi : [-h, \alpha)$ is also a solution of the above IVP with $x^\phi_t \in N$, $t \in [0, \alpha)$, then the result on unique continuation of solutions in Section 3 yields $\alpha \leqslant \beta$ and $x^\phi(t) = y(t)$, $t \in [-h, \alpha)$.

For any $\phi \in W_c$, the function $x : \mathbb{R} \to \mathbb{R}^n$ defined by $x_t = u^*(P_c\phi)(t)$, $t \in \mathbb{R}$, is continuously differentiable and satisfies Eq. (4.3.2). Consequently, $x'(t) = Lx_t + r_\delta(x_t)$, $t \in \mathbb{R}$. In particular, $\phi'(0) = L\phi + r_\delta(\phi)$. Using $\phi \in W_c \subset N$ and $r_\delta|_N = r|_N$, $\phi \in X_f$ follows. Thus, $W_c \subset X_f$.

Recall from Section 3.5 that there is an n-dimensional subspace $E \subset C^1$ which is a complement of $Y = T_0 X_f$ in C^1. If $e_1, \dots, e_n$ is a basis for E, then using the decomposition $C^1 = C^1_s \oplus C_c \oplus C_u$ of C^1, for each $i \in \{1, \dots, n\}$ we have

$$e_i = s_i + c_i + u_i$$

for some $s_i \in C^1_s$, $c_i \in C_c$, $u_i \in C_u$. As $C_c \oplus C_u \subset Y$, we have $s_i \notin Y$. Then the subspace $\hat{E}$ spanned by the vectors

$$\hat{e}_i = e_i - c_i - u_i, \quad i \in \{1, \dots, n\},$$

is also an n-dimensional complementary subspace of Y in C^1, and in addition $\hat{E} \subset C_s^1$. Therefore, without loss of generality, we may assume $E \subset C_s^1$. Then

$$C_s^1 = E \oplus \left(C_s^1 \cap Y\right),$$

$$Y = \left(C_s^1 \cap Y\right) \oplus C_c \oplus C_u,$$

and

$$C^1 = E \oplus \left(C_s^1 \cap Y\right) \oplus C_c \oplus C_u = E \oplus Y.$$

Let $P : C^1 \to C^1$ denote the projection along E onto Y. There is an open neighbourhood V of 0 in X_f so that $P : V \to Y$ is a manifold chart of X_f. Set $Y_0 = P(V)$. The inverse of $P : V \to Y_0$ is C^1-smooth. If $\delta > 0$ is sufficiently small, then $W_c \subset V$ and $PW_c \subset Y_0$. In order to complete the proof of (i) in Theorem 4.1.1, it is enough to show that PW_c is a $\dim C_c$-dimensional Lipschitz submanifold of Y. Indeed,

$$PW_c = \left\{P\left(\phi + w_c(\phi)\right) \colon \phi \in C_{c,0}\right\} = \left\{\phi + Pw_c(\phi) \colon \phi \in C_{c,0}\right\}.$$

As $w_c(\phi) \in C_s^1 \oplus C_u$, we have

$$Pw_c(\phi) \in \left(C_s^1 \cap Y\right) \oplus C_u.$$

Thus, PW_c is the graph of the Lipschitz continuous map

$$\left\{\phi \in C_c \colon |\phi|_1 < \delta\right\} \ni \chi \mapsto Pw_c(\chi) \in \left(C_s^1 \cap Y\right) \oplus C_u.$$

This completes the proof of Theorem 4.1.1.

4.4. *Discussion*

It is also true that the local center manifold W_c given in Theorem 4.1.1 is a C^1-submanifold of X_f. The proof will appear in [131]. It is based on the fact that for the global center manifold W of the modified Eq. (4.3.1)

$$W \subset \left\{\phi \in C^1 \colon \left|(\mathrm{id}_{C^1} - P_c)\phi\right|_1 < \delta\right\},$$

and r_δ is C^1-smooth on the subset $\{\phi \in C^1 \colon |(\mathrm{id}_{C^1} - P_c)\phi|_1 < \delta\}$ of C^1 with bounded derivative. The techniques of [54] or [133] can be modified to our situation in order to show that the map $w : C_c \to C_s^1 \oplus C_u$ is C^1-smooth.

Another way to obtain C^1-smooth center manifolds is to consider, for some $a > 0$, the time-a map

$$F_a : \Omega_a \to X_f,$$

and construct a local center manifold of F_a at its fixed point 0. However, as a 2-dimensional ordinary differential equation example shows in [130], the obtained center manifold of F_a is not necessarily a locally invariant center manifold of the semiflow F. There is a standard technique to overcome this difficulty (see, e.g., [130]). The idea is that the modification of the map F_a should be done through the modification of the semiflow F. This requires a modification and extension of F from a small neighbourhood of $[0, a] \times \{0\}$ in Ω to a certain global semiflow. This is a nontrivial task. It is an open problem to work out the complete proof by using this approach.

Local bifurcation results for functional differential equations with state-dependent delay through the center manifold reduction would require C^k-smooth local center manifolds also with $k > 1$. As far as we know such results are not available at the moment.

A first step towards the proof of a C^k-smooth center manifold could be a C^k-smooth version of the results of Section 3. Then a C^k-smooth time-a map could be the basis to construct a C^k-smooth center manifold as suggested above for $k = 1$.

Another possible way is the extension of the approach explained in this section. Notice that it does not require the existence of a smooth semiflow. We remark that this idea worked for a construction of C^k-smooth unstable manifolds under natural conditions on f which are satisfied by equations with state-dependent delay [129].

5. Hopf bifurcation

Hopf bifurcation is the phenomenon that under certain conditions small periodic orbits appear close to a stationary point when in the underlying differential equation a parameter is varied and passes a critical value. In this section we state a Hopf bifurcation theorem for differential equations with state-dependent delay which has recently been proved by M. Eichmann [65]. The equation considered is a parametrized version of Eq. (1.0.1), namely

$$x'(t) = g(\alpha, x_t). \tag{5.0.1}$$

The map $g : J \times U \to \mathbb{R}^n$ in Eq. (5.0.1) is defined on the product of an open interval $J \subset \mathbb{R}$ and an open subset $U \subset C^1 = C^1([-h, 0], \mathbb{R}^n)$, with $h > 0$ and $n \in \mathbb{N}$. Let $C = C([-h, 0], \mathbb{R}^n)$ and let C^2 denote the Banach space of twice continuously differentiable functions $\phi : [-h, 0] \to \mathbb{R}^n$, with the norm given by $\|\phi\|_{C^2} = \|\phi\|_C + \|\phi'\|_C + \|\phi''\|_C$. The set

$$U^* = U \cap C^2$$

is an open subset of C^2. The following hypotheses on smoothness are assumed.

- (H1) The mapping $g : J \times U \to \mathbb{R}^n$ is continuously differentiable.
- (H2) For each $(\alpha, \phi) \in J \times U$ the partial derivative $\mathrm{D}_2 g(\alpha, \phi)$ of g with respect to ϕ extends to a continuous linear map

$$\mathrm{D}_{2,e} g(\alpha, \phi) : C \to \mathbb{R}^n.$$

(H3) The mapping

$$J \times U \times C \ni (\alpha, \phi, \chi) \mapsto \mathrm{D}_{2,e} g(\alpha, \phi)\chi \in \mathbb{R}^n$$

is continuous.

(H4) The restriction $g^* = g|J \times U^*$ is twice continuously differentiable.

(H5) For each $(\alpha, \phi) \in J \times U^*$ the second order partial derivative $D_2^2 g^*(\alpha, \phi): C^2 \times C^2 \to \mathbb{R}^n$ of g^* with respect to ϕ has a continuous bilinear extension

$$\mathrm{D}_{2,e}^2 g^*(\alpha, \phi): C^1 \times C^1 \to \mathbb{R}^n.$$

(H6) The mappings

$$J \times U^* \times C^1 \times C^1 \ni (\alpha, \phi, \chi_1, \chi_2) \mapsto \mathrm{D}_{2,e}^2 g^*(\alpha, \phi)(\chi_1, \chi_2) \in \mathbb{R}^n$$

and

$$J \times U^* \times C^1 \ni (\alpha, \phi, \chi) \mapsto \mathrm{D}_{2,e}^2 g^*(\alpha, \phi)(\chi, \cdot) \in L\big(C^2, \mathbb{R}^n\big)$$

are continuous.

The hypotheses (H1)–(H3) imply that each map $g(\alpha, \cdot): U \to \mathbb{R}^n$, $\alpha \in J$, satisfies the hypotheses (S1)–(S3) of Theorem 3.2.1. Notice that condition (H3) is weaker than continuity of the map

$$J \times U \ni (\alpha, \phi) \mapsto \mathrm{D}_{2,e} g(\alpha, \phi) \in L\big(C, \mathbb{R}^n\big).$$

In (H4), differentiability refers to the norm given by $\|(\alpha, \phi)\| = |\alpha| + \|\phi|_{C^2}$ on $\mathbb{R} \times C^2$. Notice that condition (H6) is weaker than continuity of the map

$$J \times U^* \ni (\alpha, \phi) \mapsto \mathrm{D}_{2,e}^2 g^*(\alpha, \phi) \in L^2\big(C^1, \mathbb{R}^n\big),$$

where $L^2(C^1, \mathbb{R}^n)$ denotes the Banach space of continuous bilinear maps $C^1 \times C^1 \to \mathbb{R}^n$, with the appropriate norm.

Suppose $\phi^* \in U^* \subset C^2$ satisfies

$$g^*\big(\alpha, \phi^*\big) = 0 \quad \text{for all } \alpha \in J,$$

so that ϕ^* is a stationary point for all $\alpha \in J$.

For $\alpha \in J$, set $L(\alpha) = \mathrm{D}_2 g(\alpha, \phi^*)$, and let $A(\alpha)$ denote the generator of the strongly continuous semigroup on C given by the IVP

$$y'(t) = \mathrm{D}_{2,e} g(\alpha, \phi^*) y_t, \quad y_0 = \chi \in C.$$

The spectral assumptions for the Hopf bifurcation theorem from [65] are the following.

(L1) There is a continuously differentiable map $\lambda : I \to \mathbb{C}$, $I \subset J$ an open interval, such that each $\lambda(\alpha)$, $\alpha \in I$, is a simple eigenvalue of $A(\alpha)$.

(L2) For some $\alpha_0 \in I$, $Re\,\lambda(\alpha_0) = 0$ and $\omega_0 = Im\,\lambda(\alpha_0) > 0$ and

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}(Re\,\lambda)(\alpha_0) \neq 0.$$

(L3) For every integer $k \in \mathbb{Z} \setminus \{-1, 1\}$, $\mathrm{i}k\omega_0$ is not an eigenvalue of $A(\alpha_0)$.

The following local Hopf bifurcation theorem is obtained in [65]:

THEOREM 5.0.1. *Suppose* (H1)–(H6) *and* (L1)–(L3) *hold. Then there are an interval $M \subset \mathbb{R}$ with $0 \in M$ and continuously differentiable mappings $u^* : M \to C^1$, $\omega^* : M \to \mathbb{R}$ and $\alpha^* : M \to I$ with*

$$u^*(0) = \phi^*, \quad \alpha^*(0) = \alpha_0, \quad \omega^*(0) = \omega_0$$

such that for each $a \in M$ there is a periodic solution $x : \mathbb{R} \to \mathbb{R}^n$ of the equation

$$x'(t) = g\big(\alpha^*(a), x_t\big)$$

with $x_0 = u^*(a)$ and with period $\frac{\omega^*(a)}{2\pi}$.

To our knowledge, Theorem 5.0.1 is the first Hopf bifurcation result for differential equations with state-dependent delay. A related earlier result is due to H.L. Smith [189] who proved bifurcation of periodic solutions from a stationary point for a system of integral equations with state-dependent delay, by reduction to a Hopf bifurcation theorem of Hale and de Oliveira [95] for equations with time-invariant but parameter-dependent delay.

6. Differentiability of solutions with respect to parameters

6.1. *Preliminaries*

This section deals with nonautonomous parametrized state-dependent delay systems of the form

$$x'(t) = g\big(t, x(t), x\big(t - \tau(t, x_t, \sigma)\big), \theta\big), \quad t \in [0, T], \tag{6.1.1}$$

with initial condition

$$x(t) = \phi(t), \quad t \in [-h, 0]. \tag{6.1.2}$$

Here σ and θ are parameters in the delay function τ and in g belonging to normed linear spaces Σ and Θ, respectively. In the sequel we consider also the initial function ϕ in the IVP (6.1.1)–(6.1.2) as parameters, and denote the corresponding solution by $x(\cdot; \phi, \sigma, \theta)$, and its segment function at t by $x(\cdot; \phi, \sigma, \theta)_t$.

Suppose, e.g., a system of the form

$$y'(s) = \tilde{g}\big(s, y(s), y\big(s - \tilde{\tau}(s, y_t)\big)\big), \quad s \in [t_0, t_0 + T]$$

is given. Then introducing $t = s - t_0$ and $x(t) = y(t + t_0)$ we can transform the equation into the form (6.1.1) with $g(t, \psi, u, \theta) = \tilde{g}(t + \theta, \psi, u)$ with $\theta = t_0$, and $\tau(s, \psi, \sigma) = \tilde{\tau}(s + \sigma, \psi)$ with $\sigma = t_0$. In this case $\Sigma = \Theta = \mathbb{R}$. Of course, (6.1.1) contains more general cases as well, e.g., σ and θ can be coefficient functions in the delay function τ and g, respectively. In this case Σ and Θ will be infinite dimensional function spaces.

As we have seen in Section 3, in general the IVP (6.1.1)–(6.1.2) has a unique solution only if the initial function ϕ is Lipschitz continuous, or equivalently, if ϕ belongs to the Banach space $W^{1,\infty}$ of absolutely continuous functions $\phi : [-h, 0] \to \mathbb{R}^n$ with essentially bounded derivatives, with the norm defined by

$$|\phi|_{W^{1,\infty}} = \max\big\{|\phi|_C, \operatorname{ess\,sup}\big\{\big|\phi'(s)\big| \colon s \in [-h, 0]\big\}\big\}.$$

We define the parameter space for the IVP (6.1.1)–(6.1.2) as

$$\Gamma = W^{1,\infty} \times \Sigma \times \Theta,$$

and the norm on Γ by

$$|\gamma|_\Gamma = \big|(\phi, \sigma, \theta)\big|_\Gamma = |\phi|_{W^{1,\infty}} + |\sigma|_\Sigma + |\theta|_\Theta.$$

We assume throughout this section that $\Omega_1 \subset \mathbb{R}^n$, $\Omega_2 \subset \mathbb{R}^n$, $\Omega_3 \subset \Theta$, $\Omega_4 \subset C$ and $\Omega_5 \subset \Sigma$ are open subsets of the respective spaces, $T > 0$ is finite or $T = \infty$ (in the latter case $[0, T]$ means $[0, \infty)$), and

- (D1) (i) $g : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \times \Theta \supset [0, T] \times \Omega_1 \times \Omega_2 \times \Omega_3 \to \mathbb{R}^n$ is continuous; and
  - (ii) g is locally Lipschitz continuous with respect to its second, third and fourth variables in the following sense: For every $\alpha \in (0, T]$, for every compact subsets $M_i \subset \Omega_i$ $(i = 1, 2)$ of $\mathbb{R}^n$, and for every closed and bounded subset $M_3 \subset \Omega_3$ of Θ there exists $L_1 = L_1(\alpha, M_1, M_2, M_3)$ such that $|f(t, v, w, \theta) - f(t, \bar{v}, \bar{w}, \bar{\theta})| \leqslant L_1(|v - \bar{v}| + |w - \bar{w}| + |\theta - \bar{\theta}|_\Theta)$, for $t \in [0, \alpha]$, $v, \bar{v} \in M_1$, $w, \bar{w} \in M_2$, and $\theta, \bar{\theta} \in M_3$;
- (D2) (i) $\tau : \mathbb{R} \times C \times \Sigma \supset [0, T] \times \Omega_4 \times \Omega_5 \to \mathbb{R}$ is continuous, $0 \leqslant \tau(t, \psi, \sigma) \leqslant h$ for $t \in [0, T]$, $\psi \in \Omega_4$, and $\sigma \in \Omega_5$; and
  - (ii) $\tau(t, \psi, \sigma)$ is locally Lipschitz-continuous in ψ and σ in the following sense: For every $\alpha \in (0, T]$, for every compact subset $M_4 \subset \Omega_4$ of C and for every closed, bounded subset $M_5 \subset \Omega_5$ of Σ there exists a constant $L_2 = L_2(\alpha, M_4, M_5)$ such that $|\tau(t, \psi, \sigma) - \tau(t, \bar{\psi}, \bar{\sigma})| \leqslant L_2(|\psi - \bar{\psi}|_C + |\sigma - \bar{\sigma}|_\Sigma)$ for $t \in [0, \alpha]$, $\psi, \bar{\psi} \in M_4$, and $\sigma, \bar{\sigma} \in M_5$.

We, of course, assume that a parameter $\bar{\gamma} = (\bar{\phi}, \bar{\sigma}, \bar{\theta}) \in \Gamma$ satisfies the compatibility condition

$$\bar{\phi}(0) \in \Omega_1, \quad \bar{\phi}\big(-\tau\big(0, \bar{\phi}, \bar{\sigma}\big)\big) \in \Omega_2, \quad \bar{\theta} \in \Omega_3, \quad \bar{\phi} \in \Omega_4, \quad \text{and} \quad \bar{\sigma} \in \Omega_5. \tag{6.1.3}$$

It is known [57] that the IVP (6.1.1)–(6.1.2) has a unique solution for each parameter $(\bar{\phi}, \bar{\sigma}, \bar{\theta}) \in \Gamma$, moreover, the solution is Lipschitz continuous with respect to the parameters [99]. We denote the open ball with radius δ centered at $\bar{\gamma}$ in Γ by $G_\Gamma(\bar{\gamma}, \delta)$, i.e., $G_\Gamma(\bar{\gamma}, \delta) = \{\gamma \in \Gamma\colon\ |\gamma - \bar{\gamma}|_\Gamma < \delta\}$. The next result is proved, e.g., in [99].

THEOREM 6.1.1. *Suppose* (D1)(i)–(ii) *and* (D2)(i)–(ii). *For any* $\bar{\gamma} = (\bar{\phi}, \bar{\sigma}, \bar{\theta}) \in \Gamma$ *satisfying* (6.1.3) *there exist* $\alpha > 0$, $\delta > 0$ *and* $L = L(\alpha, \bar{\gamma}, \delta)$ *such that the IVP* (6.1.1)–(6.1.2) *has a unique solution on* $[-h, \alpha]$ *for any* $\gamma \in G_\Gamma(\bar{\gamma}, \delta)$, *and*

$$\big|x(\cdot;\gamma)_t - x(\cdot;\bar{\gamma})_t\big|_{W^{1,\infty}} \leqslant L|\gamma - \bar{\gamma}|_\Gamma \quad \textit{for } t \in [0, \alpha], \ \gamma \in G_\Gamma(\bar{\gamma}, \delta).$$

6.2. *Pointwise differentiability with respect to parameters*

In this subsection we study differentiability of the function $\gamma \mapsto x(t;\gamma)$ where t is fixed. In addition to (D1)(i)–(ii) and (D2)(i)–(ii) we need

(D1) (iii) $g\colon \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \times \Theta \supset [0, T] \times \Omega_1 \times \Omega_2 \times \Omega_3 \to \mathbb{R}^n$ is continuously differentiable with respect to its second, third and fourth variables;

(D2) (iii) $\tau\colon \mathbb{R} \times C \times \Sigma \supset [0, T] \times \Omega_4 \times \Omega_5 \to [0, \infty)$ is continuously differentiable with respect to its second and third variables.

As it was shown in Section 3.2, solutions corresponding to a parameter value from the parameter set

$$\Pi = \big\{(\phi, \sigma, \theta) \in \Gamma\colon\ \phi'(0) = g\big(0, \phi(0), \phi\big(-\tau(0, \phi, \sigma)\big), \theta\big),\ \phi \in C^1\big\}$$

are continuously differentiable on $[-h, \alpha]$. The key point of the proof of the following result is the same as that of Theorem 3.2.1, namely, the differentiability of the evaluation map $Ev\colon C^1 \times [-h, 0] \to \mathbb{R}^n$.

THEOREM 6.2.1. *Suppose* (D1)(i)–(iii) *and* (D2)(i)–(iii), $(\bar{\phi}, \bar{\sigma}, \bar{\theta}) \in \Pi$, *and let* $\delta > 0$ *and* $\alpha > 0$ *be such that the IVP* (6.1.1)–(6.1.2) *has a unique solution on* $[-h, \alpha]$ *for any* $\gamma \in G_\Gamma(\bar{\gamma}, \delta)$. *Then for any* $t \in [0, \alpha]$ *the function*

$$x(t;\cdot)\colon \Gamma \supset G_\Gamma(\bar{\gamma}, \delta) \to \mathbb{R}^n$$

is differentiable at $\bar{\gamma}$, *and its derivative is given by*

$$\mathrm{D}_2 x(t;\bar{\gamma})u = z(t;\bar{\gamma}, u), \qquad u \in \Gamma,$$

where $z(\cdot;\bar{\gamma}, u)$ *is the solution of the time-dependent delay system*

$$z'(t;\bar{\gamma}, u) = \mathrm{D}_2 g\big(t, \bar{x}(t), \bar{x}\big(t - \bar{r}(t)\big), \bar{\theta}\big) z(t;\bar{\gamma}, u)$$

$$
\begin{aligned}
&\quad + \mathrm{D}_3 g\big(t, \bar{x}(t), \bar{x}\big(t - \bar{r}(t)\big), \bar{\theta}\big)\Big(-\bar{x}'\big(t - \bar{r}(t)\big)\mathrm{D}_2\tau(t, \bar{x}_t, \bar{\sigma}) \\
&\quad \times z(\cdot; \bar{\gamma}, u)_t + z\big(t - \bar{r}(t); \bar{\gamma}, u\big) - \bar{x}'\big(t - \bar{r}(t)\big)\mathrm{D}_3\tau\big(t, \bar{x}_t, \bar{\sigma}\big)u^{\sigma}\Big) \\
&\quad + \mathrm{D}_4 g\big(t, \bar{x}(t), \bar{x}\big(t - \bar{r}(t)\big), \bar{\theta}\big)u^{\theta}, \quad t \in [0, \alpha], \\
z(t; \bar{\gamma}, u) &= u^{\phi}(t), \quad t \in [-r, 0],
\end{aligned}
$$

and where $\bar{x}(t) = x(t; \bar{\gamma})$, $\bar{r}(t) = \tau(t, \bar{x}_t, \bar{\sigma})$, *and* $u = (u^{\phi}, u^{\sigma}, u^{\theta}) \in \Gamma$.

We refer to [99] for the proof of Theorem 6.2.1. Here we just make some remarks on the choice of the norm on Γ. It is clear that at some point in the proof of Theorem 6.2.1 it is necessary to be able to differentiate the composite function $F(t, \psi) = \psi(-\tau(t, \psi))$. Suppose $\psi \in C^1$ is fixed, and consider

$$
\begin{aligned}
F(t, \psi + u) - F(t, \psi) &= \psi\big(-\tau\big(t, \psi + u\big)\big) + u\big(-\tau(t, \psi + u)\big) - \psi\big(-\tau(t, \psi)\big) \\
&= \psi'\big(-\tau(t, \psi)\big)\big(-\tau(t, \psi + u) + \tau(t, \psi)\big) \\
&\quad + u\big(-\tau(t, \psi)\big) + \omega(t, \psi, u) + u\big(-\tau(t, \psi + u)\big) \\
&\quad - u\big(-\tau(t, \psi)\big),
\end{aligned}
$$

where

$$
\begin{aligned}
\omega(t, \psi, u) = \psi\big(-\tau(t, \psi + u)\big) - \psi\big(-\tau(t, \psi)\big) \\
- \psi'\big(-\tau(t, \psi)\big)\big(-\tau(t, \psi + u) + \tau(t, \psi)\big).
\end{aligned}
$$

Therefore we expect that

$$
\mathrm{D}_2 F(t, \psi)u = -\psi'\big(-\tau(t, \psi)\big)\mathrm{D}_2\tau(t, \psi)u + u\big(-\tau(t, \psi)\big)
$$

using an appropriate norm on the domain. The assumptions $\psi \in C^1$, (D2)(iii) and the chain rule combined imply immediately that $|\omega(t, \psi, u)|/|u|_C \to 0$ as $|u|_C \to 0$. But to control the term $u(-\tau(t, \psi + u)) - u(-\tau(t, \psi))$ the C-norm is not suitable, we need the stronger $W^{1,\infty}$-norm: The Mean Value Theorem yields

$$
\frac{|u(-\tau(t, \psi + u)) - u(-\tau(t, \psi))|}{|u|_{W^{1,\infty}}} \leqslant \big|\tau(t, \psi + u) - \tau(t, \psi)\big|,
$$

and the right-hand side of the preceding inequality tends to 0 as $|u|_{W^{1,\infty}} \to 0$, due to the continuity of τ. Therefore $\mathrm{D}_2 F$ defined above is, in fact, the derivative of the function $F(t, \cdot)\colon W^{1,\infty} \to \mathbb{R}^n$ at $\psi \in C^1$ for any t.

6.3. *Differentiability with respect to parameters in norm*

Since the condition $\bar{\gamma} \in \Pi$ in the previous subsection may be inconvenient for certain applications, we explore different spaces to study differentiability in it for the case when the initial function and the solution segments are only $W^{1,\infty}$ functions.

First we introduce some notation and definitions. $W_\alpha^{1,p}$ $(1 \leqslant p < \infty)$ denotes the Banach space of absolutely continuous functions $\psi : [-h, \alpha] \to \mathbb{R}^n$ of finite norm

$$|\psi|_{W_\alpha^{1,p}} = \left(\int_{-h}^{\alpha} \left|\psi(s)\right|^p + \left|\psi'(s)\right|^p \,\mathrm{d}s \right)^{1/p}.$$

Similarly, $W_\alpha^{1,\infty}$ denotes the Banach space $W_\alpha^{1,\infty}([-h,\alpha],\mathbb{R}^n)$.

Consider a linear space Y and let $|\cdot|$ and $\|\cdot\|$ be two norms defined on Y. We say that $(Y, |\cdot|)$ is a quasi-Banach space with respect to the norm $\|\cdot\|$ if for any $r > 0$ the set $\{y \in Y\colon\ \|y\| \leqslant r\}$ is complete in the norm $|\cdot|$. See [96].

In addition to (D1)(i)–(iii) and (D2)(i)–(iii) we use in this subsection the following condition

(D2) (iv) $\tau : \mathbb{R} \times C \times \Sigma \supset [0,T] \times \Omega_4 \times \Omega_5 \to [0,\infty)$ is continuously differentiable with respect to its first variable; and

(v) $\mathrm{D}_1\tau$, $\mathrm{D}_2\tau$ and $\mathrm{D}_3\tau$ are locally Lipschitz continuous in the following sense: For every $\alpha \in (0,T]$, for every compact subset $M_4 \subset \Omega_4$ of C and for every closed, bounded subset $M_5 \subset \Omega_5$ of Σ there exists a constant $L_3 = L_3(\alpha, M_4, M_5)$ such that

$$\left|\mathrm{D}_1\tau(t,\psi,\sigma) - \mathrm{D}_1\tau\left(t,\bar{\psi},\bar{\sigma}\right)\right| \leqslant L_3\left(\left|\psi-\bar{\psi}\right|_C + |\sigma-\bar{\sigma}|_\Sigma\right),$$

$$\left\|\mathrm{D}_2\tau(t,\psi,\sigma) - \mathrm{D}_2\tau\left(t,\bar{\psi},\bar{\sigma}\right)\right\|_{\mathcal{L}(C,\mathbb{R})} \leqslant L_3\left(\left|\psi-\bar{\psi}\right|_C + |\sigma-\bar{\sigma}|_\Sigma\right),$$

$$\left\|\mathrm{D}_3\tau(t,\psi,\sigma) - \mathrm{D}_3\tau\left(t,\bar{\psi},\bar{\sigma}\right)\right\|_{\mathcal{L}(\Sigma,\mathbb{R})} \leqslant L_3\left(\left|\psi-\bar{\psi}\right|_C + |\sigma-\bar{\sigma}|_\Sigma\right)$$

for $t \in [0,\alpha]$, $\psi, \bar{\psi} \in M_4$, and $\sigma, \bar{\sigma} \in M_5$.

Hale and Ladeira [96] investigated differentiability of solutions to the constant delay equation

$$x'(t) = f\left(x(t), x(t-\tau)\right)$$

with respect to the delay, τ. They showed by means of an extension of the Uniform Contraction Principle to quasi-Banach spaces that the map

$$[0,h] \to W_\alpha^{1,1}, \quad \tau \mapsto x(\cdot;\tau)$$

is differentiable. Note that in their proof the integral norm of $W_\alpha^{1,1}$ played a crucial role; it can be replaced by a more general $W_\alpha^{1,p}$-norm, but not by the stronger $W_\alpha^{1,\infty}$-norm. This result suggests that the set $W_\alpha^{1,\infty}$ equipped with the norm $|\cdot|_{W_\alpha^{1,p}}$ could possibly be used as the state space for solutions. It might be a reasonable choice since (see, e.g., [99]) the parameter map $(\phi,\theta,\sigma)\mapsto x(\cdot;\phi,\theta,\sigma)_t$ is Lipschitz continuous in both the $|\cdot|_{W^{1,\infty}}$ and $|\cdot|_{W^{1,p}}$-norms while the time map $t\mapsto x(\cdot;\phi,\theta,\sigma)_t$ is continuous only in the $|\cdot|_{W^{1,p}}$, but not in the $|\cdot|_{W^{1,\infty}}$-norm. This indicates that the set $W^{1,\infty}$ equipped with the $|\cdot|_{W^{1,p}}$-norm (which is not a Banach space, it is only a quasi-Banach space with respect to the $|\cdot|_{W^{1,\infty}}$-norm) could be considered as a "natural" state space for state-dependent delay equations.

We follow the usual procedure to study differentiability with respect to parameters: Introducing $y(t)=x(t)-\tilde\phi(t)$ where $\tilde\phi$ is the extension of ϕ to $[-h,\alpha]$ by $\tilde\phi(t)=\phi(0)$ for $0<t\leqslant\alpha$, we rewrite the IVP (6.1.1)–(6.1.2) as a fixed point equation $S(y,\phi,\theta,\sigma)=y$, with the operator S given by

$$S(y,\phi,\theta,\sigma)(t)=\begin{cases}0, & t\in[-h,0],\\ \displaystyle\int_0^t g\big(u,y(u)+\tilde\phi(u),\Lambda\big(u,y_u+\tilde\phi_u,\sigma\big),\theta\big)\,\mathrm{d}u, & t\in[0,\alpha],\end{cases}$$

and with $\Lambda(t,\psi,\sigma)=\psi(-\tau(t,\psi,\sigma))$. In order to apply the Uniform Contraction Principle in this setting we need continuous differentiability of S with respect to y, ϕ, θ and σ in the $W^{1,p}_\alpha$ norm. It turns out that instead of the pointwise differentiability of Λ with respect to ψ and σ studied in the previous subsection it is enough to have the differentiability of the composite function $t\mapsto\Lambda(t,x_t,\sigma)$ with respect to x and σ in a norm of "L^p-type", for $x\in W^{1,\infty}_\alpha$.

Brokate and Colonius [29] studied equations of the form

$$x'(t)=f\big(t,x\big(r\big(t,x(t)\big)\big)\big),\quad t\in[a,b]$$

and investigated differentiability of the composition operator

$$A: W^{1,\infty}\big([a,b];\mathbb{R}\big)\supset\bar X\to L^p\big([a,b];\mathbb{R}\big),\quad A(x)(t)=x\big(r\big(t,x(t)\big)\big).$$

They assumed that r is twice continuously differentiable satisfying $a\leqslant r(t,v)\leqslant b$ for all $t\in[a,b]$ and $v\in\mathbb{R}$, and considered as domain of A the set

$$\bar X=\Big\{x\in W^{1,\infty}\big([a,b];\mathbb{R}\big)\colon \text{there exists } \epsilon>0 \text{ s.t. } \frac{\mathrm{d}}{\mathrm{d}t}\big(r\big(t,x(t)\big)\big)\geqslant\epsilon \\ \text{for a.e. } t\in[a,b]\Big\}.$$

It was shown in [29] that under these assumptions A is continuously differentiable with the derivative given by

$$\big(\mathrm{D}A(x)u\big)(t)=x'\big(r\big(t,x(t)\big)\big)\mathrm{D}_2r\big(t,x(t)\big)u(t)+u\big(r\big(t,x(t)\big)\big)$$

for $u\in W^{1,\infty}([a,b],\mathbb{R})$.

Both the strong $W^{1,\infty}$ norm on the domain and the weak L^p norm on the range, together with the choice of the domain seemed to be necessary to obtain the results in [29]. Note that Manitius in [160] used a similar domain and norm when he studied linearization for a class of state-dependent delay systems.

Clearly, to apply the Uniform Contraction Principle to the operator S we have to use the same norm on the domain and range of S. It turns out that the following "product norm" preserves the essential properties of the different norms used in [96] and [29]: Let $x \in W^{1,\infty}_\alpha$, and decompose x as $x = y + \tilde{\phi}$, (where $\phi(t) = x(t)$ for $t \in [-r, 0]$, and $\tilde{\phi}$ is the extension of ϕ to $[-r, \alpha]$ by $\tilde{\phi}(t) = \phi(0)$), and define the norm of x by

$$|x|_{X^{1,p}_\alpha} = \left(\int_0^\alpha \left|y'(u)\right|^p \mathrm{d}u\right)^{1/p} + |\phi|_{W^{1,\infty}},$$

and consider the normed linear space $X^{1,p}_\alpha \equiv (W^{1,\infty}_\alpha, |\cdot|_{X^{1,p}_\alpha})$. The norm $|\cdot|_{X^{1,p}_\alpha}$ is weaker than the $|\cdot|_{W^{1,\infty}_\alpha}$ norm, but stronger than the $|\cdot|_{W^{1,p}_\alpha}$ norm (see [106]).

This norm is "strong enough" that the methods of [29], with minor modifications, provide differentiability of the composition map

$$B : X^{1,p}_\alpha \times \Sigma \supset U_1 \times U_2 \to L^p\big([0, \alpha]; \mathbb{R}^n\big), \qquad B(x, \sigma)(t) = \Lambda(t, x_t, \sigma),$$

on a suitable domain $U_1 \times U_2$. On the other hand, $|\cdot|_{X^{1,p}_\alpha}$ is "weak enough" that using the differentiability of the operator B above we can obtain differentiability of the operator $S : X^{1,p}_\alpha \times W^{1,\infty} \times \Theta \times \Sigma \supset V_1 \times V_2 \times V_3 \times V_4 \to X^{1,p}_\alpha$ with respect to y, ϕ, θ and σ. Moreover it is possible to use a modification of the Uniform Contraction Principle to get differentiability of the fixed point (the solution of the IVP) with respect to the parameters ϕ, θ and σ in the $|\cdot|_{X^{1,p}_\alpha}$ norm. Since this product norm is stronger than the $|\cdot|_{W^{1,p}_\alpha}$ norm, the result implies the differentiability of solutions in the latter norm as well. For more details and the proof of the next result we refer to [106].

THEOREM 6.3.1. *Suppose* (D1)(i)–(iii) *and* (D2)(i)–(v), *and let* $\bar{\delta} > 0$ *and* $\alpha > 0$ *be such that the IVP* (6.1.1)–(6.1.2) *has a unique solution on* $[-h, \alpha]$ *for any* $\gamma \in G_\Gamma(\bar{\gamma}, \bar{\delta})$, *and suppose there exists* $\epsilon > 0$ *such that the solution* $\bar{x} = x(\cdot; \bar{\gamma})$ *satisfies*

$$\frac{\mathrm{d}}{\mathrm{d}t}\big(t - \tau(t, \bar{x}_t, \bar{\sigma})\big) \geqslant \epsilon \quad a.e.\ t \in [0, \alpha].$$

Then there exists $\delta > 0$ *such that the functions*

$$\Gamma \supset G_\Gamma(\bar{\gamma}, \delta) \to X^{1,p}_\alpha, \qquad \gamma \mapsto x(\cdot; \gamma)$$

and

$$\Gamma \supset G_\Gamma(\bar{\gamma}, \delta) \to W^{1,p}_\alpha, \qquad \gamma \mapsto x(\cdot; \gamma)$$

are continuously differentiable.

An application of differentiability of solutions with respect to parameters was given in [100], where estimation of unknown parameters in state-dependent delay equations was studied. The goal of the work was to find a parameter value which minimizes a least square cost function $P(\gamma) = \sum_{k=1}^{N}(x(t_i;\gamma) - y_i)^2$, where y_i $(i = 1, \dots, N)$ are measurements of the solution at time points t_i $(i = 1, \dots, N)$. The so-called method of quasilinearization was adopted and numerically tested for state-dependent delay equations for cases where the parameters were infinite dimensional, e.g., the initial function. This algorithm is based on Newton's method and uses the derivative of P, hence also $\mathrm{D}_2x(t;\gamma)$. The convergence of the estimation method was observed also for those cases where $\mathrm{D}_2x(t;\gamma)$ did not exist in the pointwise sense of Theorem 6.2.1 but only in a norm, as stated in Theorem 6.3.1. For example, when the initial function is approximated by piecewise linear splines, then Theorem 6.2.1 is not applicable to solutions corresponding to such parameters since they belong to $W^{1,\infty}$ but not to C^1.

7. Periodic solutions via fixed point theory

Over the last 40 years the most general results on existence of periodic solutions to autonomous delay differential equations, with constant and also with state-dependent delay, have been obtained using topological fixed point theorems and the fixed point index. The first step in applying these tools is the construction of a *return map*: For initial data in a suitably chosen set K one follows the solution segments until they return to K. Fixed points of the return map define periodic solutions. The search for a suitable set K requires a priori knowledge about the desired periodic solutions and about their role in the global dynamics generated by the delay equation. Hypotheses of fixed point theorems must also be satisfied. This indicates that in general the search for K may be a nontrivial task. The finer (more restrictive) a structure a domain K of a return map has, the more qualitative information about the periodic solution is provided.

It is not uncommon that domains of return maps or their closures contain a known fixed point which also is a stationary point of the semiflow. Therefore, to obtain a *nonconstant* periodic solution, one needs to find another fixed point. While impossible in case the trivial fixed point is globally attracting, there is hope in case the trivial fixed point is unstable. A weak topological notion of instability, which proved very useful, is Browder's concept of *ejectivity* [30]. A fixed point x of a map $f : M \to N$, N a topological space and $M \subset N$, is called ejective if there exists a neighbourhood V of x in M so that for each $y \in V \setminus x$ there is $j \in \mathbb{N}$ with $f^j(y) \notin V$. Ejectivity was deeply explored and first applied by Nussbaum (see, e.g., [174,175]), who also proved the first result on existence of periodic solutions for differential equations with state-dependent delay [174]. In the next subsection, Section 7.1, we describe a very general result of Mallet-Paret, Nussbaum, and Paraskevopoulos [156] on existence of periodic solutions and its proof, which is based on ejectivity.

The Section 7.2 deals with a model from Section 2.6 where the delay is governed by a differential equation which involves the state. This example was studied by Arino, Hadeler and Hbid [7] and Magal and Arino [148] and shows some of the specific difficulties caused by state-dependent delays in the search for periodic solutions.

Ejectivity is used also in the existence proofs in [4,136,137,151].

Of course, ejectivity does not adequately reflect the unstable behaviour of solutions to decent differential equations. Close to unstable manifolds of equilibria, or in cones around such unstable manifolds, solutions to delay and other differential equations behave much more regular than expressed by ejectivity. Accordingly one can prove existence of periodic solutions and global bifurcation from stationary points also without recourse to ejectivity. Schauder's fixed point theorem and simple calculations of the fixed point index suffice if only unstable solution behaviour close to equilibria is exploited to a larger extent. This was done in [202,203] and in Chapter XV of [54] for a class of RFDEs with constant delay. For equations with state-dependent delay, a proof of existence of periodic solutions along these lines has not yet been carried out.

Beyond existence and outside the scope of purely topological tools, uniqueness and stability of periodic orbits are of interest. In Section 7.3 we present results from [205, 208] where return maps are contractions or have a locally attracting fixed point, with the associated periodic orbit nontrivial, stable and hyperbolic. The approach applies to single equations and systems with state-dependent delay where the nonlinearities are given by functions which do not vary much on long intervals.

7.1. *A general result by continuation*

In [156] Mallet-Paret, Nussbaum and Paraskevopoulos prove existence of periodic solutions for a rather general class of scalar RFDEs which include equations with state-dependent delay. They consider Eq. (1.0.1) with $f : C \to \mathbb{R}$ continuous, $C = C([-h, 0], \mathbb{R})$, and assume that there are $\tau_0 \in (0, h]$ and a locally Lipschitz continuous function $g : \mathbb{R} \to \mathbb{R}$ satisfying the negative feedback condition

$$\xi g(\xi) < 0 \quad \text{for all } \xi \neq 0$$

so that

$$f(\phi) = g\big(\phi(-\tau_0)\big)$$

for ϕ in the closed hyperplane H given by $\phi(0) = 0$. In particular, $f(0) = 0$, τ_0 is the delay on H, and the constant function zero is a solution to Eq. (1.0.1). In Section 3 we mentioned the property (alL) from [156] of being *almost locally Lipschitzian*, to which condition (L) in Section 3 is closely related. Property (alL) requires local Lipschitz estimates for f which involve the norm on C but only arguments of f which are Lipschitz continuous. For f with property (alL) and at most linear growth Lipschitz continuous initial data $\phi \in C$ uniquely determine solutions $x : [-h, \infty) \to \mathbb{R}$ of Eq. (1.0.1) with $x_0 = \phi$. Also bounds for solutions and continuous dependence on initial data are established. Under a more restrictive negative feedback condition, now for the functional f and involving also data $\phi \in C \setminus H$, it is shown that segments x_t, $t \geqslant 0$, of solutions which start from $x_0 = \phi$ in a closed bounded convex set

$$G^+ \subset \big\{\phi \in H \colon \phi(t) \geqslant 0 \text{ for all } t \in [-h, 0]\big\}$$

return to G^+ at a certain well-defined zero $z_2 = z_2(x_0) > 0$ provided the solution has at least one sign change on $(0, \infty)$ and a zero thereafter. On a subset $U^+ \subset G^+$ which is open with respect to the topology on G^+ induced by C the previous result yields a continuous return map $\Gamma_0 : U^+ \to G^+$. Actually, more is achieved here for later use: $\Gamma_0 = \Gamma(\cdot, 0)$, for a homotopy $\Gamma : U^+ \times [0, 1] \to G^+$ of modified return maps $\Gamma(\cdot, \alpha)$ associated with the members of a one-parameter family of RFDEs; the equation at $\alpha = 1$ has the property that the values of initial data on $[-h, -\tau_0)$ have no influence on the solution.

The extremal point $0 \in G^+$ of G^+ does not belong to U^+, and each fixed point of the return map Γ_0 defines a non-constant periodic solution of Eq. (1.0.1). A fixed point exists if the fixed point index $i_{G^+}(\Gamma_0, U^+)$ of Γ_0 is defined and non-zero.

The remaining steps towards

$$i_{G^+}\bigl(\Gamma_0, U^+\bigr) \neq 0 \tag{7.1.1}$$

require some sort of linearization of the RFDE at the zero solution, in order to describe and exploit conditions for instability of the zero solution. Here the hypothesis (aFd) that f is *almost Fréchet differentiable* at 0 comes into play. It requires that the restriction of f to the space $C^{0,1} = C^{0,1}([-h, 0], \mathbb{R})$ of Lipschitz continuous data has a derivative at $0 \in C^1 \subset C^{0,1}$. The properties (alL) and (aFd) combined imply that this derivative $\mathrm{D}(f|_{C^{0,1}})(0)$ extends to a continuous linear map $\mathrm{D}_e(f|_{C^{0,1}})(0) : C \to \mathbb{R}$, like in conditions (S2) and (S3) from Section 3. A look back at the hypotheses on f shows that the recipe *freeze the delay at equilibrium, then linearize* mentioned in Section 3 is not sufficient to compute this extended derivative. The desired linear equation has the form

$$\begin{aligned} v'(t) &= \mathrm{D}_e(f|_{C^{0,1}})(0)v_t \\ &= -\beta\, v(t) - \gamma v(t - \tau_0) \end{aligned} \tag{7.1.2}$$

with constants $\beta \geqslant 0$, $\gamma \geqslant 0$, and is considered for initial data in the Banach space $C_{\tau_0} = C([-\tau_0, 0], \mathbb{R})$. On the cone

$$K = \bigl\{\phi \in C_{\tau_0} \colon\ \phi(t) \geqslant 0 \text{ for all } t \in [-\tau_0, 0],\ \phi(0) = 0\bigr\}$$

there is a return map $S_{\beta,\gamma} : K \to K$ similar to Γ_0, given by the solutions to Eq. (7.2.2), with $S_{\beta,\gamma}(0) = 0$. In case the zero solution of Eq. (7.2.2) is unstable the trivial fixed point $0 \in K$ has index zero;

$$i_K(S_{\beta,\gamma}, 0) = 0. \tag{7.1.3}$$

To see this one can use ejectivity as in [174,175], or follow [176], or proceed as in [203,54].

The major steps in the proof of (7.2.1) are a reduction to

$$i_{G^+}\bigl(\Gamma_1, U^+\bigr) \neq 0$$

by homotopy invariance, and the deduction of the preceding inequality from (7.2.3). In this last step all basic properties normalization, additivity, homotopy invariance, and commutativity of the fixed point index are instrumental.

The skillful proof in [156] overcomes more obstacles than this brief outline indicates. The main theorem of [156] yields a wide variety of results on existence of periodic solutions for explicitly given RFDEs, in particular also for equations with multiple state-dependent delays of the form

$$x'(t) = G\big(x(t), x\big(t - r_1\big(x(t)\big)\big), \ldots, x\big(t - r_m\big(x(t)\big)\big)\big).$$

7.2. *Periodic solutions when delay is described by a differential equation*

As mentioned above, Nussbaum [174] used the ejective fixed point theorem to prove the existence of periodic solutions to the equation

$$x'(t) = -\alpha x\big(t - 1 - \big|x(t)\big|\big)\big(1 - x^2(t)\big).$$

Alt [4] and Kuang and Smith [136,137] obtained periodic solutions for equations where the delay is given by a threshold condition.

While the major steps towards existence of so-called slowly oscillating periodic solutions remain essentially the same as for delay differential equations with constant delays, the technical details become more involved when delays are state-dependent. This refers both to the construction of the domain of a return map and to the verification that a trivial fixed point is ejective. To illustrate this we describe in the sequel work of Arino, Hadeler and Hbid [7] and of Magal and Arino [148] for the system

$$\begin{cases} x'(t) = -f\big(x\big(t - r(t)\big)\big), \\ r'(t) = q\big(x(t), r(t)\big). \end{cases} \tag{7.2.1}$$

Here the variation of the delay is determined by an ordinary differential equation. Standing assumptions are that the functions $f : \mathbb{R} \to [-M, M]$, $M > 0$, and $q : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ are continuously differentiable, with

$$xf(x) > 0 \quad \text{for all } x \neq 0 \text{ and } f \text{ nondecreasing,}$$

and that for some fixed reals $r_2 > r_1 > 0$ and for all $x \in \mathbb{R}$,

$$q(x, r_2) < 0 < q(x, r_1).$$

Let $C = C([-r_2, 0], \mathbb{R})$. The hypotheses ensure that the IVP given by the system (7.2.1) and initial data $(\phi, r_0) \in C \times [r_1, r_2]$ with ϕ Lipschitz continuous has a unique solution $(x, r) = (x^{\phi, r_0}, r^{\phi, r_0})$, with x defined on $[-r_2, \infty)$ and r defined on $[0, \infty)$. The solution component x is Lipschitz continuous with $|x'(t)| \leqslant M$ for all $t > 0$, and the hypothesis on q yields $r_1 < r(t) < r_2$ for all $t > 0$.

Incidentally, note that the system (7.2.1) can be reformulated as a special case of (1.0.1) with $n = 2$, $h = r_2$, $U = (\mathbb{R} \times [0, h])^{[-h,0]}$, and the corresponding functional being given by $(-f(\phi(-r_0)), q(\phi(0), r_0))$ for $(\phi, r_0) \in U$.

It also follows that the function $q(0,\cdot)$ has zeros in $[r_1, r_2]$. The additional hypothesis

$$\frac{\partial q}{\partial r}(0,r) < 0 \quad \text{on } [r_1, r_2]$$

implies that there is exactly one zero r_0^* of $q(0,\cdot)$ in $[r_1, r_2]$, and that the constant solution $r^*: t \mapsto r_0^*$ of the autonomous equation

$$r' = q(0,r)$$

is asymptotically stable. Below we shall see that this fact causes complications in view of ejectivity of a fixed point corresponding to the constant solution of system (7.2.1) given by $x(t) = 0$ and r^*.

In order to obtain that $t \mapsto t - r(t)$ is strictly increasing it is furthermore assumed that

$$q(x,r) < 1 \quad \text{on } \mathbb{R} \times [r_1, r_2].$$

The notion of a slowly oscillating solution, which is familiar from work on equations with constant delay $h > 0$ like, e.g.,

$$x'(t) = -f\big(x(t-h)\big)$$

and means that zeros are isolated and spaced at distances larger than the delay h, is modified for the x-components of solutions to the system (7.2.1) according to the following definition: A function $x : [t_0, \infty) \to \mathbb{R}$, $t_0 \in \mathbb{R}$, is called slowly oscillating if its zeros form a disjoint union of closed intervals Z whose left endpoints have no accumulation point and are spaced at distances not less than r_2, with

$$\lim_{t \nearrow a} \operatorname{sign}\big(x(t)\big) = -\lim_{s \searrow b} \operatorname{sign}\big(x(s)\big)$$

at each compact interval $Z = [a,b]$ with $t_0 < a$. Notice that the definition allows nonconstant functions which are zero on some unbounded interval $[t_1, \infty)$, $t_1 > t_0$, a phenomenon which occurs among the first components of solutions to the system (7.2.1).

The first step towards a return map is to show that certain initial data define solutions with slowly oscillating first component. In [7] it is shown that the first components of solutions with initial value component ϕ in the cone

$$\Gamma = \big\{\phi \in C([-r_2, 0]; \mathbb{R})\colon \text{ there exists } \theta \in [-r_2, -r_1] \text{ so that } \phi(\theta) = 0$$
$$\text{and } \phi(s) < 0 \text{ for } s < \theta;\, 0 \leqslant \phi(\theta) \leqslant \phi(0) \text{ for } \theta \leqslant s \leqslant 0\big\}$$

return to Γ at a sequence of times whose distances are not less than r_2. More precisely, if (x, r) is a solution with initial value (ϕ, r_0) and $\pm\phi \in \Gamma$ then there are two sequences, possibly finite, of points t_i^* and zeros t_i of x in $[0, \infty)$ such that

$$t_0^* \geqslant 0, \quad t_i^* + (r_2 - r_1) \leqslant t_{i+1} \leqslant t_{i+1}^* - r_1$$

and $\pm(-1)^{i+1}x$ is nondecreasing on the interval $[t_i^*, t_{i+1}^*]$. In particular, $\pm(-1)^i x_{t_i^*} \in \Gamma$ for each index $i > 0$. To reach the conclusion, it is required that the delay variation satisfies the smallness condition $(r_2 - r_1)|f(x)| < |x|$ for $x \neq 0$.

Uniqueness with respect to initial data is needed, and the domain for a return map should be convex. Therefore Γ must be modified. The smaller set

$$\Gamma_1 = \{\phi \in \Gamma\colon \phi \text{ is Lipschitzian and nondecreasing}\}$$

is convex, and closed in $C^{0,1}([-r_2, 0], \mathbb{R})$. Let $E = \Gamma_1 \times [r_1, r_2]$. For each integer $j \geqslant 1$, it is now natural to introduce operators P_j and P_j^+ on the space E by

$$P_j(\phi, r_0) = \bigl(x_{t_j^*}, r\bigl(t_j^*\bigr)\bigr),$$

$$P_j^+(\phi, r_0) = \bigl((-1)^j x_{t_j^*}, r\bigl(t_j^*\bigr)\bigr).$$

Obviously, the existence of $P_j(\phi, r_0)$ is subject to the condition that $t_1^*, t_2^*, \dots, t_{j-1}^*$ exist. If this condition is satisfied but the solution starting from $(x_{t_{j-1}^*}, r(t_{j-1}^*))$ does not cross zero, then it is proved in [7] that $x(t) \to 0$ and $r(t) \to r^*$ as $t \to \infty$. In this case, one defines $P_j(\phi, r_0) = (0, r^*)$.

P_1 sends bounded sets of E into bounded sets of the product space $C([-r_2, 0], \mathbb{R}) \times [r_1, r_2]$, and P_1^+ is a compact and continuous operator from E into itself.

It is important to know when a first positive zero $t_1 = t_1(\phi, r_0)$ exists: This property is ensured for every $(\phi, r_0) \in (\Gamma_1 \cup (-\Gamma_1)) \times [r_1, r_2]$ if there exist $M > 0$ and $R_0 > 0$ with $M(r_2 - r_1) \leqslant R_0$, $|f(x)| \leqslant M$ for $x \in \mathbb{R}$ and $(2r_1 - r_2)|f(x) \geqslant |x|$ for $|x| \leqslant R_0$.

Unfortunately, the fixed point $(0, r^*)$ of any return map defined in a set containing $\{0\} \times [r_1, r_2]$ is not ejective. This follows immediately from positive invariance of the set $\{0\} \times [r_1, r_2]$ and asymptotic stability of the solution r^* to the equation $r' = q(0, r)$.

In order to obtain ejectivity smaller convex subsets

$$E_K = \bigl\{(\phi, r_0) \in E\colon \bigl|r_0 - r_0^*\bigr| \leqslant K\|\phi\|_C, \|\phi\|_C = \bigl|\phi(0)\bigr|\bigr\}$$

for $K > 0$ are introduced which contain from the obstacle for ejectivity $\{0\} \times [r_1, r_2]$ only the point $(0, r_0^*)$. For $R > 0$ and $K > 0$ let

$$E_{R,K} = \bigl\{(\phi, r_0) \in E\colon \|\phi\|_C \leqslant R, \bigl|r_0 - r_0^*\bigr| \leqslant K\|\phi\|_C\bigr\},$$

and define

$$\Gamma_2 = \Bigl\{\phi \in \Gamma_1\colon \phi(0) = \sup_{-r_2 \leqslant s \leqslant 0} \bigl|\phi(s)\bigr|\Bigr\}.$$

In order for P_1^+ to map $(\Gamma_2 \times [r_1, r_2]) \cap E_{R,K}$ into E_K, a restriction on r_1 is needed. In [7] it is shown that for each $R > 0$ there exist $\tilde{r}_1 > 0$ and $K > 0$ such that for each $r_1 > \tilde{r}_1$

the operator P_1^+ maps $(\Gamma_2 \times [r_1, r_2]) \cap E_{R,K}$ into E_K. The key to the proof of the above statement is that for each $R > 0$ there exists $C(r_1) \in (0, 1)$ such that

$$\left\| x_{t_1^*}^{\phi, r_0} \right\|_C \geqslant C(r_1) \|\phi\|_C \tag{7.2.2}$$

for each $(\phi, r_0) \in \Gamma_2 \times [r_1, r_2]$ with $0 < \|\phi\|_C \leqslant R$. Estimates of this type exclude super-exponential decay of slowly oscillating solutions and play an important role in work on the global dynamics of equations with constant delay.

The map $(\phi, r_0) \mapsto -x_{t_1^*}^{\phi, r_0}$ sends $E = \Gamma_1 \times [r_1, r_2]$ into Γ_2. The fact that $t_1 = t_1(\phi, r_0)$ is a zero of $x = x^{\phi, r_0}$ and integration of the first equation in (7.2.1) yield the estimate

$$\left\| x_{t_1^*}^{\phi, r_0} \right\|_C \leqslant M r_2,$$

for each $(\phi, r_0) \in E$. With this preparation, we can define $R = M r_2$ and introduce the set

$$X = \left\{ \phi \in \Gamma_2 \colon \ \|\phi\|_C \leqslant R, \ \operatorname*{ess\,sup}_{-r_2 \leqslant s \leqslant 0} \left| \phi'(s) \right| \leqslant M \right\}.$$

Choose $K > 0$ and $\tilde{r}_1 > 0$ as above, assume $r_1 > \tilde{r}_1$, and set

$$Y = \bigl(X \times [r_1, r_2] \bigr) \cap E_{R,K}.$$

Y is closed and convex, and the iterate P_1^2 defines a map $P : Y \to Y$.

It remains to show that $(0, r_0^*)$ is an ejective fixed point of P. Ejectivity of $(0, r_0^*)$ is a consequence of instability of the constant solution $t \mapsto (0, r_0^*)$ to the system (7.2.1), which in turn follows from instability for the linearized system. In [7] the technique *freeze the delay at equilibrium, then linearize* mentioned in Section 3.4 is applied to the first equation in (7.2.1) and yields

$$y'(t) = -y\bigl(t - r_0^*\bigr), \tag{7.2.3}$$

which is unstable for $r_0^* > \frac{\pi}{2}$ when f normalized so that $f'(0) = 1$. More precisely, the eigenvalues of the generator of the semigroup generated by Eq. (7.2.2) on the space

$$C\bigl(\bigl[-r_0^*, 0\bigr], \mathbb{R}\bigr)$$

with largest real part are a complex conjugate pair $u \pm i v$ in the open right halfplane, and the associated realified generalized eigenspace U is 2-dimensional and consists of segments of solutions

$$\mathbb{R} \ni t \mapsto \mathrm{e}^{ut} \bigl(a \cos(vt) + b \sin(vt) \bigr)$$

to Eq. (7.2.3). For $(a, b) \neq (0, 0)$ these solutions are slowly oscillating, due to $|v| < \frac{\pi}{r_0^*}$. The problem is now to transfer such unstable solution behaviour to the slowly oscillating solution components x of solutions (x, r) to the nonlinear system (7.2.1) which start from small initial data $(\phi, \rho) \in Y$ in the other state space $C([-r_2, 0], \mathbb{R}) \times [r_1, r_2]$. The proof in [7] proceeds by contradiction. Ejectivity means that there exists $\epsilon > 0$ so that for each $(\phi, r_0) \in Y$ with $0 < \|\phi\|_C \leqslant \epsilon$ there is an integer $j > 0$ such that $(x, r) = (x^{\phi,r_0}, r^{\phi,r_0})$ and $t_j^* = t_j^*(\phi, r_0)$ satisfy $\|x_{t_j^*}\|_C \geqslant \epsilon$ or $|r(t_j^*) - r_0^*| \geqslant \epsilon$. It can be shown that in case the previous statement on ejectivity is not true, then there exists a constant $d > 0$ so that for all $(\phi, r_0) \in Y$ with $\|\phi\|_C \leqslant \epsilon$ and for all $t \geqslant 0$ we have $\|x_t^{\phi,r_0}\|_C \leqslant d\epsilon$ and $|r(t) - r_0^*| \leqslant d\epsilon$.

The next step is to show that the spectral projection Π_U onto the realified generalized eigenspace U associated with $u \pm v$ in $C([-r_0^*, 0], \mathbb{R})$ satisfies

$$\gamma := \inf_{\|\phi\|=1, \phi\in\tilde{\Gamma}_2} \|\Pi_U \phi\| > 0, \tag{7.2.4}$$

under a further restriction about the variation of the delay

$$r_2 - r_1 < \delta \tag{7.2.5}$$

for some constant $\delta > 0$ (explicitly given in [7]) that depends on r_0^* only. Here and in what follows, $\tilde{\Gamma}_2$ is defined in a similar fashion as Γ_2, except we replace Γ_1 and Γ by $\tilde{\Gamma}_1$ and $\tilde{\Gamma}$ respectively, where the domain of ϕ is $[-r_0^*, 0]$ rather than $[-r_2, 0]$.

Let $\sup_{j\in\mathbb{N}} \|x_{t_j^*}\phi, r_0\|_C = \tilde{\epsilon} \leqslant \epsilon$. We can choose an integer $j_0 > 0$ so that $\|x_{t_{j_0}^*}\phi, r_0\|_C \geqslant C\tilde{\epsilon}$ and thus, $|y(t_{j_0}^*)| \geqslant C\tilde{\epsilon}\gamma$, where $y(t) = \Pi_U x_t$, C and γ are given in (7.2.2) and (7.2.4). Note that the first equation of the system (7.2.1) can be written as $x'(t) = -x(t - r^*) + o(\tilde{\epsilon})$ for large t, by using the linearization and the fact that $|x'(t)| \leqslant M$ and $|r(t) - r_0^*| \leqslant d\tilde{\epsilon}$ for all $t \geqslant 0$.

Therefore,

$$y'(t) = A_U y(t) + \mathrm{o}(\tilde{\epsilon})$$

with $A_U = \left(\begin{smallmatrix} \alpha & -\beta \\ \beta & \alpha \end{smallmatrix}\right)$. It then follows that

$$\frac{\mathrm{d}}{\mathrm{d}t}\left|y(t)\right| = \alpha\left|y(t)\right| + \mathrm{o}(\tilde{\epsilon}).$$

Therefore,

$$\left|y(t)\right| = \mathrm{e}^{\alpha(t-\sigma)}\left[\left|y(\sigma)\right| + \int_\sigma^t \mathrm{e}^{\alpha(\sigma-s)}\mathrm{o}(\tilde{\epsilon})\,\mathrm{d}s\right],$$

which implies

$$\left|y(t)\right| \geqslant \mathrm{e}^{\alpha(t-t_{j_0}^*)}\left[C\tilde{\epsilon}\gamma - \frac{\mathrm{o}(\tilde{\epsilon})}{\alpha}\right] \geqslant \mathrm{e}^{\alpha(t-t_{j_0}^*)}\frac{C\gamma}{2}\tilde{\epsilon}$$

if $\tilde{\epsilon}$ is small. This leads to a contradiction since $y(t) = \Pi_U x_t$ should be bounded by a constant multiple of $\tilde{\epsilon}$ for all $t \geqslant 0$.

In summary, under a few technical conditions including the negative feedback condition on the state variable x and the delay r, the smallness of the delay variation and an instability condition for an associated linear equation, Arino, Hadeler and Hbid obtain in [7] the existence of periodic solution with slowly oscillating first component.

In [148] Magal and Arino obtain such periodic solutions under weaker conditions on the delay variation—(7.2.5) is no longer needed—by means of a different argument which uses a modification of ejectivity and employs other cones of initial data. Magal and Arino consider a cone that was already used by Kuang and Smith in [136,137], namely,

$$\begin{aligned}E_{\mathrm{KS}} = \big\{&(\phi, r_0) \in C^{0,1}\big([-r_2, 0], \mathbb{R}\big) \times [r_1, r_2]\colon \phi(-r_0) = 0\\ &\text{and } \phi \text{ nonincreasing on } [-r_0, 0]\big\}.\end{aligned}$$

Using arguments similar to those in [7] one can show that for $\epsilon = \pm 1$ and $(\epsilon\phi, r_0) \in E_{KS}$ there are reals $t_i^* = t_i^*(\phi, r_0)$ and zeros $t_i = t_i(\phi, r_0)$ of $x = x^{\phi,r_0}$ such that $t_0 = -r_0$, $t_0^* = 0$, $t_i^* \leqslant t_{i+1}$, $t_i = t_i^* - r(t_i^*)$ for integers $i \geqslant 0$, and $\epsilon(-1)^{i+1}x(t)$ is nonincreasing on $[t_i^*, t_{i+1}^*]$, $x(t_i) = 0$, and $x(t_i^*) \neq 0$ if $\phi(0) \neq 0$. So, $(\epsilon(-1)^{i+1}x_{t_i^*}, r(t_i^*)) \in E_{\mathrm{KS}}$. Let $X_0 = C^1([-r_2, 0], \mathbb{R}) \times [r_1, r_2]$, introduce

$$E_0 = \big\{(\phi, r_0) \in X_0\colon \phi'(s) \geqslant 0 \text{ for } s \in [-r_0, 0], \phi(-r_0) = 0, \phi'(0) = 0\big\},$$

and define the return maps P_j and P_j^+ on E_0 exactly as in [7]. For each integer $j > 0$ one finds $P_{2j}(E_0) \subset E_0$.

The fact that for initial data $(\phi, r_0) \in C^1([-r_2, 0], \mathbb{R}) \times [r_1, r_2]$ the map $t \mapsto t - r^{\phi,r_0}(t)$ is increasing implies that on $[0, \infty)$ the solution $(x^{\phi,r_0}, r^{\phi,r_0})$ does not depend on the restriction of ϕ to $[-r_2, -r_0)$. The preceding observation suggests to consider initial data $(\tilde{\phi}, r_0)$ with $\tilde{\phi}$ defined only on $[-r_0, 0]$, and secondly, to modify the fixed point problem by transforming the initial delay r_0 to 1. Let

$$X_1 = C^1\big([-1, 0], \mathbb{R}\big) \times [r_1, r_2].$$

Magal and Arino introduce maps

$$L : X_0 \to X_1 \quad \text{and} \quad Q : X_1 \to X_0$$

by

$$L(\phi, r_0) = (\psi, r_0), \quad \psi(s) = \phi(s\, r_0)$$

and

$$Q(\psi, r_0) = (\phi, r_0), \quad \phi(s) = \psi(s/r_0) \quad \text{on } [-r_0, 0],$$

$$\phi(s) = \frac{\psi'(-1)}{r_0}(s - r_0) \quad \text{on } [-r_2, -r_0).$$

Let E_1 denote the analogue of E_0 where X_0 and r_0 are replaced by X_1 and 1, respectively. E_1 is closed and convex, and $Q(E_1) \subset E_0$, $L(E_0) \subset E_1$. The maps $F_{2j} = L \circ P_{2j} \circ (Q|E_1)$ send E_1 into E_1. We have $F_2(0, r_0^*) = (0, r_0^*)$, and fixed points (ϕ, r_0) of F_2 with $\phi \neq 0$ yield periodic solutions of the system (7.2.1) with slowly oscillating first component. However, the second component of $F_2 : E_1 \to C^1([-1,0], \mathbb{R}) \times [r_1, r_2]$ is not continuous at points $(0, r_0)$ with $r_0 \neq r_0^*$, which requires a further modification. The map $\tilde{F}_2 : E_1 \to E_1$ resulting from this is continuous and compact (with respect to the topology on $C^1([-1,0], \mathbb{R})$) and retains the property that nontrivial fixed points define periodic solutions to (7.2.1) with slowly oscillating first component. It is shown in [148] that

(i) $\tilde{F}_2(0, r_0^*) = (0, r_0^*)$,

(ii) $\tilde{F}_2(\{0\} \times [r_1, r_2]) \subset \{0\} \times [r_1, r_2]$, and

(iii) for every $\epsilon > 0$ there exist $c > 0$ and $\gamma \in [0, 1)$ with

$$\left|\left(\tilde{F}_1^{2j}\right)_2(\phi, r_0) - r_0^*\right| \leqslant \gamma \left|r_0 - r_0^*\right|$$

for all $(\phi, r_0) \in E_1$ with

$$\|\phi\|_{C^1([-1,0],\mathbb{R})} + \left|r_0 - r_0^*\right| \leqslant \epsilon$$

and

$$\|\phi\|_{C^1([-1,0],\mathbb{R})} \leqslant c\left|r_0 - r_0^*\right|,$$

and for all integers $j \geqslant 1$.

Here the index 2 denotes the second component of the map $\tilde{F}_2^{2j}$. Properties (ii) and (iii) combined exclude that the fixed point $(0, r^*)$ of $\tilde{F}_2$ is ejective. Now the modification of ejectivity comes into play. Let X be a Banach space, $A \subset Y \subset X$, and assume that $g : Y \to Y$ has a fixed point $x_0 \in \partial_Y A$. Then x_0 is called semi-ejective on $Y \setminus A$ if there is a neighbourhood V of x_0 in Y so that for each $y \in V \setminus A$ there is an integer $m \geqslant 1$ with

$$g^m(y) \in Y \setminus V.$$

Arguments similar to those in [7] which exploit the instability of Eq. (7.2.3) yield in [148] that the fixed point $(0, r_0^*)$ is semi-ejective on $E_1 \setminus (\{0\} \times [r_1, r_2])$. Finally, an extension of the ejective fixed point theorem in [148] to the case of semi-ejective fixed points guarantees that $\tilde{F}_2$ has a fixed point (ϕ, r_0) with $\phi \neq 0$, which defines the desired periodic solution.

7.3. *Attracting periodic orbits*

In [205] the system (2.2.1)–(2.2.2)

$$x'(t) = v\left(\frac{c}{2}s(t - r) - w\right),$$

$$cs = \left|x(t-s) + w\right| + \left|x(t) + w\right|,$$

with positive parameters c, r, w, is studied. The function $v : \mathbb{R} \to \mathbb{R}$ is assumed to satisfy a negative feedback condition

$$\delta v(\delta) < 0 \quad \text{for all } \delta \neq 0.$$

For continuous and bounded v the system defines a continuous semiflow on a set O which is open in a compact set $M \subset C = C([-h,0],\mathbb{R})$, with $h = \frac{4w}{c} + r$. The set M consists of Lipschitz continuous functions. The set O contains a closed subset K of initial data which define solutions whose segments x_t return to K, after an excursion into the ambient space O. This yields a continuous return map, on a domain without stationary points. If v is Lipschitz continuous and close to constants in $(-\infty, -\beta]$ and $[\beta, \infty)$, respectively, with $\beta > 0$ sufficiently small, then one can estimate the Lipschitz constant of the return map in terms of Lipschitz constants for v and for its restrictions $v|_{(-\infty,-\beta]}$ and $v|_{[\beta,\infty)}$; under suitable further assumptions the return map becomes a contraction. The unique fixed point of the contracting return map belongs to a periodic orbit of the system (2.2.1)–(2.2.2) which is stable and exponentially attracting with asymptotic phase.

The observation which led to the method used in [205] and in earlier work on equations with constant delays is the following: If the function $g : \mathbb{R} \to \mathbb{R}$ in the equation

$$y'(t) = g\big(y(t-1)\big) \tag{7.3.1}$$

is constant on some interval I and if y remains long enough in I, say, for $t_0 - 1 \leqslant t \leqslant t_0$, then for $t \geqslant t_0$ the solution y depends only on $y(t_0)$ and $g(I)$. This can be used to design simple-looking nonlinearities g, representing negative feedback, for which periodic solutions of Eq. (7.3.1) can be computed explicitly, see, e.g., Chapter XV in [54]. Moreover, solutions which start from initial data close to the periodic orbit eventually merge into it. This is an extremely strong kind of orbital stability, giving hope that also for nonlinearities which are only close to constants on some intervals attracting periodic orbits may exist. If instead of the scalar equation (7.3.1) more generally systems are considered then suitable nonlinearities which are constant on nontrivial intervals yield low-dimensional subsets of the state space which are positively invariant under the semiflow and absorb flowlines from a neighbourhood.

In [208] the system

$$u' = v, \tag{7.3.2}$$

$$v' = -r\,v + A(p), \tag{7.3.3}$$

$$p = \frac{c}{2}s - w, \tag{7.3.4}$$

$$cs = u(t-s) + u(t) + 2w \tag{7.3.5}$$

is studied. In contrast to the system (2.2.1)–(2.2.2) the model (7.3.2)–(7.3.5) for position control by echo is now based on Newton's law. Instead of the constant time lag $r > 0$ in Eq. (2.2.1) there is now a friction term $-rv$ in Eq. (7.3.3).

For suitable positive values of the parameters w, c, r and for certain functions $A : \mathbb{R} \to \mathbb{R}$ which represent negative feedback and are constant on $(-\infty, -\beta]$ and on $[\beta, \infty)$, with $\beta > 0$ small, the existence of a hyperbolic stable periodic orbit is established. The proof begins with a reformulation of the system as an equation of the form (1.0.1), with a continuously differentiable functional f defined on an open subset U of the space $C^1 = C^1([-h, 0], \mathbb{R}^2)$, for suitable $h > 0$. Several steps of the proof rely on the smoothness properties of the semiflow F on the solution manifold $X_f \subset U$ which are provided by Theorem 3.2.1. In X_f a thin, infinite-dimensional set I of initial data ϕ is found to which the flowlines $F(\cdot, \phi)$ return, after a journey through the ambient part of the manifold. The associated return map is not necessarily compact, which precludes an immediate application of Schauder's theorem in order to find a fixed point—not to speak of an attracting fixed point. But the return map is semiconjugate to an interval map which is differentiable. Estimates of derivatives of the interval map yield a unique, attracting fixed point of the latter, which can be lifted to the return map. The proof that the resulting periodic orbit of the system (7.3.2)–(7.3.5) is hyperbolic and stable involves a continuously differentiable Poincaré return map, on a hyperplane transversal to the periodic orbit, in addition to the previous return map on the thin set $I \subset X_f$, and a discussion of derivatives of iterates.

8. Attractors, singular perturbation, small delay, generic convergence, stability and oscillation

This section deals with limiting behaviour. Section 8.1 is concerned with long term dynamics and reports about the structure of a global attractor [132]. Section 8.2 describes work of Mallet-Paret and Nussbaum [151–155] about the asymptotic shape of periodic solutions when a parameter becomes large, Section 8.3 sketches an approach of Ouifki and Hbid [178] to existence of periodic solutions when delays are small, Section 8.4 reports about work of Bartha [21] on generic convergence of solutions, and Section 8.5 comments on further results about stability and oscillatory solution behaviour.

8.1. *An attracting disk*

The paper [132] studies the equation

$$x'(t) = -\mu x(t) + f\bigl(x\bigl(t - r\bigl(x(t)\bigr)\bigr)\bigr) \tag{8.1.1}$$

with $\mu > 0$, $f \in C^2(\mathbb{R}, \mathbb{R})$, $f(0) = 0$, $f'(u) < 0$ for all $u \in \mathbb{R}$, $r \in C^1(\mathbb{R}, \mathbb{R})$, $r(0) = 1$, and $\sup_{u \in \mathbb{R}} f(u) < \infty$ provided $r(u) \geqslant 0$ for all $u \in \mathbb{R}$. The case $\mu = 0$ can also be handled with a slight modification. Then the delayed logistic equation (or Wright's equation)

$$y'(t) = -\alpha y\bigl(t - r\bigl(y(t)\bigr)\bigr)\bigl[1 + y(t)\bigr]$$

with state-dependent delay and solutions satisfying $y(t) > -1$ is a particular case. Indeed, after the transformation $x = \log(1+y)$ we obtain

$$x'(t) = -\alpha\bigl[\mathrm{e}^{x(t-r(\mathrm{e}^{x(t)}-1))} - 1\bigr].$$

The aim is to describe the asymptotic behaviour of the slowly oscillatory solutions of Eq. (8.1.1). Here a solution x of (8.1.1) is called slowly oscillatory if $|z' - z| > r(0) = 1$ for every pair of zeros z', z of x. The results are in part analogous to those of Walther [204] for the constant delay case $r \equiv 1$.

Let I_r denote the largest subinterval of $\mathbb{R}$ with $0 \in I_r$ and $r(u) \geqslant 0$ for all $u \in I_r$. First it is shown that for every element ϕ of the space $BC((-\infty, 0], I_r)$ of bounded continuous functions from $(-\infty, 0]$ into I_r, there is a solution $x : \mathbb{R} \to \mathbb{R}$ of Eq. (8.1.1) through ϕ, i.e., x is continuous on $\mathbb{R}$, continuously differentiable on $(0, \infty)$, (8.1.1) holds for all $t > 0$, and $x|_{(-\infty,0]} = \phi$. If ϕ is Lipschitz continuous then x is unique.

In the next step four positive constants A, B, R, K are constructed such that

$$r\bigl([-B, A]\bigr) \subset (0, R],$$
$$\max_{(u,v)\in[-B,A]\times[-B,A]} \bigl|-\mu u + f(v)\bigr| \leqslant K,$$

moreover, for any solution $x : \mathbb{R} \to \mathbb{R}$ of (8.1.1) with $x|_{(-\infty,0]} \in BC((-\infty, 0], I_r)$ there exists $T \geqslant 0$ such that

$$x(t) \in [-B, A] \quad \text{for all } t \geqslant T.$$

Therefore, from the point of view of the asymptotic ($t \to \infty$) behaviour, only those solutions are interesting which have values in $[-B, A]$.

Let C_R denote the space $C([-R, 0], \mathbb{R})$ equipped with the supremum norm. The set

$$L_K = \left\{\phi \in C_R\colon\ \phi\bigl([-R, 0]\bigr) \subset [-B, A],\quad \sup_{-R\leqslant s<t\leqslant 0} \frac{|\phi(t) - \phi(s)|}{t - s} \leqslant K\right\}$$

is a compact convex subset of C_R. For every $\phi \in L_K$, Eq. (8.1.1) has a unique solution $x^\phi : [-R, \infty) \to \mathbb{R}$ with $x|_{[-R,0]} = \phi$ and $x(t) \in [-B, A]$ for all $t \geqslant 0$. Then the relations

$$F(t, \phi) = x_t^\phi, \quad t \geqslant 0, \qquad x_t^\phi(s) = x^\phi(t + s), \quad -R \leqslant s \leqslant 0,$$

define a continuous semiflow F on L_K. In the sequel, only those solutions of (8.1.1) are considered whose segments are in L_K.

Define the compact subset

$$S = \bigl\{\phi \in L_K\colon\ \mathrm{sch}\bigl(\phi, [t - 1, t]\bigr) \leqslant 1 \text{ for all } t \in [-R + 1, 0]\bigr\}$$

of L_K, where $\mathrm{sch}(\phi, [t-1, t])$ denotes the number of sign changes of ϕ on the interval $[t - 1, t]$. If x is a slowly oscillatory solution of (8.1.1), then all segments x_t belong to S.

The set S is positively invariant under the semiflow F. The restriction of F to $[0,\infty)\times S$ defines the continuous semiflow F_S on the compact metric space S. The global attractor $\mathcal{A}$ of F_S has the following properties:

(i) $\mathcal{A}$ is a compact connected subset of $S \subset L_K$.

(ii) For each $\phi \in \mathcal{A}$ there is a unique solution of (8.1.1) through ϕ on $\mathbb{R}$, which is also denoted by x^ϕ. The map $F_{\mathcal{A}} : \mathbb{R}\times\mathcal{A} \ni (t,\phi) \mapsto x_t^\phi \in \mathcal{A}$ is a continuous flow.

(iii) $\mathcal{A}$ is the union of $0 \in C_R$ and the segments x_t of the globally defined slowly oscillating solutions $x:\mathbb{R}\to[-B,A]$ of Eq. (8.1.1).

The first main result is that a Poincaré–Bendixson type theorem holds on $\mathcal{A}$: The α- and ω-limit sets of phase curves in $\mathcal{A}$ are either $\{0\}$ or periodic orbits given by slowly oscillating periodic solutions. The second main result is that in case $\mathcal{A}\neq\{0\}$, the set $\mathcal{A}$ is homeomorphic to the 2-dimensional closed unit disk so that the unit circle corresponds to a periodic orbit given by a slowly oscillating periodic solution.

Below we list some of the technical tools used in the proofs.

There is an additional assumption on the delay function r: either

$$\left|r'(u)\right| < \frac{1}{K}, \quad u \in [-B, A],$$

or

$$r \in C^2\big([-B,A],\mathbb{R}\big), \text{ and there is } a \in (0,1) \text{ with } r''(u) \leqslant a\mu\big[r'(u)\big]^2, \\ u \in [-B,A].$$

This assumption and the fact that the dependence of the delay on the state is of the simple form $r(x(t))$ seem to be crucial in several parts of the proof.

An important consequence of the above hypothesis on r is that the function

$$t \mapsto t - r\big(x(t)\big)$$

is strictly increasing for solutions of (8.1.1). Another important fact is that for a suitable weighted difference $v:\mathbb{R}\to\mathbb{R}$ of two solutions x and y on $\mathbb{R}$, an equation of the form

$$v'(t) = \alpha(t)v\big(t - r\big(x(t)\big)\big) \tag{8.1.2}$$

holds on $\mathbb{R}$ with a negative, bounded and continuous α. The backward uniqueness of solutions is a corollary.

A modified version of the well-known discrete Lyapunov functional of Mallet-Paret and Sell [150,157,158] is also introduced. Instead of on intervals with fixed length, the sign changes are counted for a solution x on intervals of the form $[t - r(x(t)), t]$. The properties are completely analogous to those of the constant delay case. In particular, this functional can be used to exclude the existence of solutions decaying to zero at ∞ or $-\infty$ faster than any exponential. By applying the discrete Lyapunov functional to a weighted difference of two solutions satisfying Eq. (8.1.2), the number of sign changes of the difference can be controlled.

A return map P on the compact convex set

$$U = \{\phi \in L_K\colon\ \phi(0) = 0,\ \phi(s) \geqslant 0 \text{ for all } s \in [-1, 0]\}$$

is defined by $P(\phi) = x^{\phi}_{z_2}$, where at z_2 the second sign change of x^{ϕ} in $(0, \infty)$ occurs, and $P(\phi) = 0$ if there is at most one sign change in $(0, \infty)$. P is not necessarily continuous on U. However, $P|_{\mathcal{A}\cap U}$ is continuous. In addition, P restricted to $\{\phi \in \mathcal{A} \cap U\colon\ P(\phi) \neq 0\}$ is a homeomorphism onto $\mathcal{A} \cap U \setminus \{0\}$. It is also an essential step that $\mathcal{A} \cap U$ is connected. The elements of $\mathcal{A} \cap U \setminus \{0\}$ are exactly those segments x_s of globally defined slowly oscillating solutions $x : \mathbb{R} \to [-B, A]$ for which $x(s) = 0$ and $x'(s) < 0$.

An asymptotic expansion for slowly oscillating solutions converging to zero as $t \to -\infty$ is also proved. It relates solutions of Eq. (8.1.1) to solutions of the associated linear equation

$$y'(t) = -\mu y(t) + f'(0)y(t-1).$$

This result is used to verify that for any two elements ϕ, ψ of $\mathcal{A}$, the difference of the solutions $x^{\phi} - x^{\psi}$ has at most one sign change in all intervals $[t - r(x^{\phi}(t)), t]$ and $[t - r(x^{\psi}(t)), t]$, $t \in \mathbb{R}$. This fact is important in the proof of the injectivity of the map

$$\Pi : \mathcal{A} \ni \phi \mapsto \begin{pmatrix} \phi(0) \\ \phi(-r(\phi(0))) \end{pmatrix} \in \mathbb{R}^2.$$

The paper [22] considers Eq. (8.1.1) in the positive feedback case, i.e., $f' > 0$, and proves certain results which are analogous to the constant delay case in [133].

We remark that in the constant delay case, it is also known that the attractor of the slowly oscillating solutions is a C^1-smooth submanifold of the phase space [210]. Another remarkable result is that the domain of attraction is an open dense subset of the phase space [159]. Whether these remain true for the state-dependent delay case are open problems.

8.2. *Limiting profiles for a singular perturbation problem*

In their series of papers [151,152,155] Mallet-Paret and Nussbaum determine the asymptotic shape, or *limiting profile*, of periodic solutions to equations of the form

$$\epsilon x'(t) = f\bigl(x(t), x\bigl(t - r\bigl(x(t)\bigr)\bigr)\bigr), \tag{8.2.1}$$

for $\epsilon \to 0$. A limiting profile is a subset Ω of the plane $\mathbb{R}^2$ which arises as limit of a sequence of solutions

$$x^k = \{\bigl(t, x^k(t)\bigr) \in \mathbb{R}^2\colon\ t \in \mathbb{R}\}, \quad k \in \mathbb{N},$$

to Eq. (8.2.1) with $\epsilon = \epsilon_k$, in case $\lim_{k\to\infty} \epsilon_k = 0$. Convergence of a sequence of closed subsets of the plane means that intersections with given compact subsets converge in the Hausdorff metric.

The standing hypotheses in [155] are the following. f is a Lipschitz continuous real-valued map defined on a square $I \times I$, $I = [-D, C]$ with $C > 0$ and $D > 0$, and $r : I \to [0, \infty)$ is Lipschitz continuous with

$$r(0) = 1 \quad \text{and} \quad r(\xi) > 0 \quad \text{for } -D < \xi < C.$$

The zero set $f^{-1}(0) \subset I \times I$ is a strictly decreasing continuous function $g : I \to I$ with $g(0) = 0$, and f is positive below its zero set and negative above it. Moreover,

$$\left|g^2(\xi)\right| < |\xi| \quad \text{on } (-D, C) \setminus \{0\}.$$

In case $r(C) > 0$ it is assumed that $g(C) = -D$ while in case $r(-D) > 0$, $g(-D) = C$. Finally, f is differentiable at $(0, 0)$ with $\mathrm{D}_2 f(0, 0)1 < D_1 f(0, 0)1$.

Notice that the distribution of the signs of f in $I \times I$ generalizes the negative feedback inequality for functions of a single variable.

The periodic solutions considered are slowly oscillating in the sense that their zeros are spaced at distances larger than $r(0) = 1$, which is the delay at equilibrium. Their minimal periods are given by 3 consecutive zeros, and they are sine-like in the sense that the period interval between 3 successive zeros consists of 3 adjacent subintervals on each of which the periodic solution is monotone. Existence of sine-like slowly oscillating periodic solutions for sufficiently small $\epsilon > 0$ is proved in [152].

Limiting profiles exist, due to a result from [152] that for every sequence of parameters $\epsilon_k > 0$ with $\lim_{k\to\infty} \epsilon_k = 0$ and for every sequence of sine-like slowly oscillating periodic solutions $x^k : \mathbb{R} \to I$ of Eq. (8.2.1) with $\epsilon = \epsilon_k$ there is a subsequence (k_j) for which the graphs x^{k_j} converge.

It may happen that the limiting profile is simply the abscissa $\mathbb{R} \times \{0\}$. Theorem 5.1 in [152] provides sufficient conditions on r which exclude this case, like for example $r'(0) \neq 0$.

The first step towards the description of nontrivial limiting profiles is an appropriate interpretation of the formal limit of Eq. (8.2.1) for $\epsilon \to 0$, which reads

$$0 = f\big(x(t), x\big(t - r\big(x(t)\big)\big)\big) \tag{8.2.2}$$

and can be considered as a difference equation in implicit form for functions on the real line. But this is too narrow, as limiting profiles may contain vertical line segments. Notice that for any point $(t, x(t))$ on a solution $x : \mathbb{R} \to I$ of Eq. (8.2.2) there is another point $(s, x(s))$ on x with

$$s = t - r\big(x(t)\big) \leqslant t \quad \text{and} \quad x(s) = g\big(x(t)\big)$$

since Eq. (8.2.2) is solved for the second argument by g. This suggests to consider the *backdating map* $\Phi : \mathbb{R} \times I \to \mathbb{R} \times I$ given by

$$\Phi(\tau, \xi) = \big(\tau - r(\xi), g(\xi)\big)$$

and its trajectories (τ_n, ξ_n), which satisfy the system

$$\begin{aligned} 0 &= f(\xi_n, \xi_{n-1}), \\ \tau_{n-1} &= \tau_n - r(\xi_n). \end{aligned}$$

Properties of the backdating map are the key to the description of limiting profiles.

Theorem 1.3 in [155] establishes that the minimal periods $p^k > 2$ of sine-like slowly oscillating periodic solutions $x^k : \mathbb{R} \to I$, $k \in \mathbb{N}$, of Eq. (8.2.1) with $\epsilon = \epsilon_k$, $\lim_{k\to\infty} \epsilon_k = 0$, are bounded.

Each nontrivial limiting profile $\Omega \subset \mathbb{R} \times I$ is periodic, i.e.,

$$\Omega = \Omega + (p, 0)$$

with the (existing) limit $p \geqslant 2$ of the minimal periods of the approximating sequence of periodic solutions, and the intersection of Ω with a suitable vertical strip of width p can be written as the union of a horizontal line segment below the abscissa, an ascending part, a horizontal line segment above the abscissa, and a descending part. The horizontal parts may be singletons, and the ascending and descending parts may contain both horizontal and vertical line segments.

The first main result, Theorem A in [155], describes a nontrivial limiting profile Ω in the following way, using the (existing) limits $\mu > 0$ of the maxima and $-\nu < 0$ of the minima of the approximating periodic solutions: There is a sequence of continuous functions $\psi_n : [-\nu, \mu] \setminus \{0\} \to \mathbb{R}$, $n \in \mathbb{Z}$, with right and left limits at 0, so that for each integer n the function $(-1)^n \psi_n$ is increasing, $\psi_n \leqslant \psi_{n+1}$, $\psi_{n+2} = \psi_n + p$, and

$$\Omega = \left(\bigcup_n \psi_n^* \cup \big(A_n \times \{0\}\big) \right) \cup \left(\bigcup_n B_n \times \{\lambda_n\} \right)$$

where

$$\psi_n^* = \big\{ \big(\psi_n(\xi), \xi\big) \colon\ 0 \neq \xi \in [-\nu, \mu] \big\},$$

$$A_n = \begin{cases} \big[\psi_n(0-), \psi_n(0+)\big] & \text{if } n \text{ is even}, \\ \big[\psi_n(0+), \psi_n(0-)\big] & \text{if } n \text{ is odd}, \end{cases}$$

and

$$B_n = \big[\psi_n(\lambda_n), \psi_{n+1}(\lambda_n)\big]$$

with

$$\lambda_n = \begin{cases} \mu & \text{if } n \text{ is even}, \\ -\nu & \text{if } n \text{ is odd}. \end{cases}$$

Moreover, there exist $\delta_0 > 0$ and $\delta_1 > 0$ so that for $0 \neq \xi \in [-\nu, \delta_0]$,

$$\psi_{2m}(\xi) = \max_{-\nu \leqslant s \leqslant \xi} \big(r(s) + \psi_{2m-1}\big(g(s)\big)\big) \tag{8.2.3}$$

while for $0 \neq \xi \in [-\delta_1, \mu]$,

$$\psi_{2m+1}(\xi) = \max_{\xi \leqslant s \leqslant \mu} \big(r(s) + \psi_{2m}\big(g(s)\big)\big). \tag{8.2.4}$$

The nonlocal *max-plus operators* given by the right-hand sides of Eqs. (8.2.3)–(8.2.4) bear analogies with linear Fredholm integral operators. To see this, replace addition in (8.2.3)–(8.2.4) by multiplication and maximization by integration. In [153,154] Mallet-Paret and Nussbaum study max-plus operators and associated eigenvalue problems; the theory is applied in [155].

Theorem B in [155] deals with monotone delay functions r and provides more detailed information about limiting profiles, in terms of f, g, r and $h = r + r \circ g$. Here the functions ψ_n for n odd are solutions to an eigenvalue problem

$$p + \psi_n(\xi) = \max_{\xi \leqslant s \leqslant \mu} \big(h(s) + \psi_n\big(g^2(s)\big)\big)$$

for a max-plus operator, with the period p as an *additive eigenvalue*. The functions ψ_n for n even are computed from ψ_n for n odd.

Theorem C in [155] establishes uniqueness of limiting profiles, under further conditions on the data f and r.

A simple-looking example for which there is a unique limiting profile is the equation

$$\epsilon x'(t) = -x(t) - kx\big(t - 1 - cx(t)\big)$$

with $k > 1$ and $c > 0$. In this case, $p = 1 + k$ and

$$\Omega \cap \big((-1, k) \times \mathbb{R}\big) = \left\{\left(\tau, \frac{1}{c}\tau\right) \colon -1 < \tau < k\right\},$$

$$\Omega \cap \big(\{k\} \times \mathbb{R}\big) = \left\{(k, \xi) \colon -\frac{1}{c} \leqslant \xi \leqslant \frac{k}{c}\right\}.$$

So Ω is uniquely determined and looks like sawteeth.

8.3. *Small delay*

In [178] Ouifki and Hbid obtain existence of periodic solutions for a system of the form

$$x'(t) = g\big(x\big(t - r(x_t)\big)\big) \tag{8.3.1}$$

with a map $g:\mathbb{R}^2 \to \mathbb{R}^2$ which satisfies $g(0)=0$, is smooth of class C^4, and has Jacobian $\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ at $0 \in \mathbb{R}^2$. Also the delay functional $r:C \to [0,h] \subset \mathbb{R}$, $C = C([-h,0];\mathbb{R}^2)$, is assumed to be smooth of class C^4, and several smallness conditions are imposed. The approach in [178] is based on a decomposition of the functional $f:C \to \mathbb{R}^2$ corresponding to the right hand side of Eq. (8.3.1) into a smooth map $f_r : C \to \mathbb{R}^2$ and a remainder term, both depending on r. The decomposition holds for arguments in a closed subset E_1 of the space $C^{0,1} = C^{0,1}([-h,0];\mathbb{R}^2)$. The set E_1 is contained in the analogue $E \subset C^1 = C^1([-h,0];\mathbb{R}^2) \subset C^{0,1}$ of the solution manifold X_f from Section 3; in [144] it was shown that a nonlinear semigroup on $C^{0,1}$ generated by equations like (8.3.1) becomes strongly continuous if restricted to E. Smallness assumptions on r yield that the set E_1 is positively invariant. Each truncated equation

$$y'(t) = f_r(y_t) \tag{8.3.2}$$

defines a semiflow on the space C, as f_r is sufficiently smooth. The delay $\mu = r(0)$ at equilibrium is then considered as a parameter; Eq. (8.3.2) is rewritten as

$$y'(t) = f_{\tilde{r}}(\mu, z_t), \tag{8.3.3}$$

with $\tilde{r}(\phi) = r(\phi) - r(0)$. Under assumptions which guarantee certain stability properties of the stationary point 0 of Eq. (8.3.3) with $\mu = 0$ and $\tilde{r}$ small, a combination of center manifold theory with a Hopf bifurcation theorem yields attracting periodic orbits $o(\mu,\tilde{r})$ of the truncated equation (8.3.2) for small $\mu > 0$ and small $\tilde{r}$. Upon that a return map is constructed following solutions of the original equation (8.3.1) which start from initial data in E_1 close to a chosen point on $o(\mu,\tilde{r})$. This requires further smallness properties of $\tilde{r}$; closeness refers to the topology of $C^{0,1}$. With respect to this topology the return map is continuous and compact, Schauder's theorem is applied, and resulting fixed points define periodic solutions of Eq. (8.3.1).

8.4. *Generic convergence*

In [21] Bartha considers the scalar equation

$$x'(t) = -\mu x(t) + f\big(x\big(t - r\big(x(t)\big)\big)\big) \tag{8.4.1}$$

assuming that $\mu > 0$, $f \in C^1(\mathbb{R},\mathbb{R})$, $f(0)=0$, $f'(u) > 0$ for all $u \in \mathbb{R}$, $r \in C^1(\mathbb{R},\mathbb{R})$, and there is $A > 0$ with

$$\big|f(u)\big| < \mu|u| \quad \text{for all } u \in \mathbb{R} \setminus (-A, A).$$

In addition, it is also required that

$$r(u) > 0 \quad \text{for all } u \in [-A, A].$$

Setting $R = \max_{u\in[-A,A]} |r(u)|$, the metric space X is defined as the space of Lipschitz continuous functions $\phi : [-R, 0] \to [-A, A]$ equipped with the metric

$$d(\phi, \psi) = \max_{s\in[-R,0]} \bigl|\phi(s) - \psi(s)\bigr|.$$

Then, for every $\phi \in X$, Eq. (8.4.1) has a unique solution $x^\phi : [-R, \infty) \to [-A, A]$ with $x^\phi|_{[-R,0]} = \phi$, and the relations

$$F(t, \phi) = x_t^\phi, \quad t \geqslant 0, \quad x_t^\phi(s) = x^\phi(t + s), \quad -R \leqslant s \leqslant 0,$$

define a continuous semiflow on X.

Using the standard ordering

$$\phi \leqslant \psi \quad \text{iff} \quad \phi(s) \leqslant \psi(s), \quad -R \leqslant s \leqslant 0,$$

it is relatively straightforward to show that the semiflow F is monotone, i.e., $F(t, \phi) \leqslant F(t, \psi)$ whenever $\phi \in X$, $\psi \in X$, $\phi \leqslant \psi$ and $t \geqslant 0$. However, the strongly order preserving property (SOP), which is a crucial hypothesis in the generic convergence theorem of Smith and Thieme in [191], does not hold in general for F. Recall that SOP of F means the monotonicity of F, and that in case $\phi \in X$, $\psi \in X$, $\phi \leqslant \psi$, $\phi \neq \psi$ there exist $t_0 > 0$ and open subsets U, V of X with $\phi \in U$ and $\psi \in V$ such that $F(t_0, U) \leqslant F(t_0, V)$. Here, for subsets S, T of X we write $S \leqslant T$ if $\phi \leqslant \psi$ holds for all $\phi \in S$ and $\psi \in T$. The main reason of the failure of the SOP property for F is that for different elements ϕ, ψ of X with $\phi \leqslant \psi$, $x^\phi(t) = x^\psi(t)$ may happen for all $t \geqslant 0$.

In [21] the SOP property is replaced by the weaker mildly order preserving property (MOP). Introduce

$$\phi <_F \psi$$

for elements ϕ, ψ of X if $\phi \leqslant \psi$, $\phi \neq \psi$, and $F(t, \phi) \neq F(t, \psi)$ for all $t \geqslant 0$. Then F is said to be MOP if it is monotone, and for every ϕ, ψ in X with $\phi <_F \psi$, there exist $t_0 > 0$ and open subsets U, V of X with $\phi \in U$ and $\psi \in V$ such that $F(t_0, U) \leqslant F(t_0, V)$.

[21] proves that F has the MOP property. An important step toward this result is that for two globally defined solutions $x : \mathbb{R} \to [-A, A]$ and $y : \mathbb{R} \to [-A, A]$ with $x_0 = y_0$, it is true that

$$x(t) = y(t) \quad \text{for all } t \in \mathbb{R}.$$

The abstract generic convergence result of Smith and Thieme from [191] is modified in [21] so that SOP is replaced by MOP. Then the main result of [21] is that there is an open dense subset Y of X such that

$$\lim_{t\to\infty} x^\phi(t) \text{ exists}$$

for all $\phi \in Y$.

8.5. *Stability and oscillation*

Several results in the literature which deal with limiting behaviour of solutions to nonautonomous differential equations with non-constant delay are also valid for equations with state-dependent delays, see, e.g., [128,222]. Most of these papers concentrate on the behaviour of given solutions, not on questions of existence, uniqueness, and continuous dependence.

Here we list a few papers where the presence of the state-dependent delay is emphasized since it causes new technical difficulties.

Kuang [135] considers the scalar nonautonomous state-dependent delay differential equation

$$x'(t) = -g\big(t, x(t)\big) - \mathrm{e}^{-\eta\tau(x_t)} f\big(t, x\big(t - \tau(x_t)\big)\big).$$

Sharp conditions for the boundedness of solutions, global and uniform stability of the trivial solution are presented.

Cooke and Huang [47] study the scalar equation

$$x'(t) = x(t)\left(a - bx(t) - \sum_{i=1}^{L} b_i x(t - r_i) - cx\big(t - \tau(x_t)\big)\right),$$

where a, b_i, c are positive constants, τ is a functional of the history of $x(\cdot)$ over all times before t. They obtain results on convergence of positive solutions, periodic and oscillatory behaviour which extend work of G. Seifert for the constant delay case.

Győri and Hartung [93] consider the linear delay differential systems

$$x'(t) = A_i(t)x\big(t - \sigma_i(t)\big) \tag{8.5.1}$$

with continuous coefficient functions $A_i : [0, \infty) \to \mathbb{R}^{n\times n}$ and continuous delay functions $\sigma_i : [0, \infty) \to \mathbb{R}$, $i \in \{1, 2\}$, such that, for some $r > 0$, $0 \leqslant \sigma_i(t) \leqslant t + r$, $t \geqslant 0$, and $\liminf_{t\to\infty}[t - \sigma_i(t)] > 0$. Assuming that the zero solution of Eq. (8.5.1) with $i = 1$ is exponentially stable, explicit neighbourhoods of A_1 and σ_1 are constructed so that if A_2 and σ_2 belong to the corresponding neighbourhoods of A_1 and σ_1, then the zero solution of Eq. (8.5.1) with $i = 2$ is also exponentially stable. As an application, among others, sufficient conditions are given to guarantee the exponential stability of the zero solution of the scalar equation

$$x'(t) = a(t)x\big(t - \tau(t, x_t)\big)$$

with delay functional τ defined by the threshold relation

$$\int_{t-\tau(t,x_t)}^{t} f(t, s, x_t)\,\mathrm{d}s = m$$

provided that the zero solution of

$$x'(t) = a(t)x\big(t - \tau(t, 0)\big)$$

is exponentially stable.

Cao, Fan and Gard [37] study the two-stage population model of Aiello, Freedman and Wu [2] with density-dependent delay. They show that no Hopf bifurcation can occur in the sense that the characteristic equation, associated with linearization at any strictly positive equilibrium, never has imaginary roots. Instability can arise together with the creation of multiple equilibria. The attractivity regions of the equilibrium points are also estimated.

Bélair [24] considers an age-structured model, and reduces it to a system of delay differential equations with state-dependent delay. Assuming that a center manifold reduction is valid, a supercritical Hopf bifurcation is established.

Rai and Robertson [182,183] study stage-structured population models with delay where the delay is a function of the total population density, and they prove positivity, boundedness and stability of the solutions.

Bartha [20] addresses the stability and convergence of solutions for a class of neutral functional differential equations with state-dependent delay. The equation is transformed into a retarded differential equation with infinite delay. The state-dependent delay causes that the transformation depends on each particular solution. For the retarded equation with infinite delay a result of Krisztin [128] can be applied to get sharp sufficient conditions for the stability of the zero solution. The second part of [20] contains attractivity results.

Pinto [180] gives conditions assuring asymptotic expansions of the form

$$y(t) = \exp\left(\int_{t_0}^{t} a(s)\,\mathrm{d}s\right)\left[\xi + \mathrm{O}\left(\int_{t}^{\infty} \lambda(s)\,\mathrm{d}s\right)\right] \quad \text{as } t \to \infty$$

for the solutions of the scalar state-dependent differential equation

$$y'(t) = a(t)y\big(t - r\big(t, y(t)\big)\big)$$

with certain $\xi \in \mathbb{R}$, $\lambda \in L_1[0, \infty)$ constructed by means of the coefficient function a and the delay function r. These results are extended to systems in [83].

Asymptotic solution behaviour for various classes of autonomous equations with state-dependent delays is investigated also in [45,46,53,104].

Gatica and Rivero [86] obtain sufficient conditions for the oscillation of all nontrivial solutions of a scalar equation with a state-dependent delay given by a threshold condition.

Domoshnitsky, Drakhlin and Litsyn [56] study the equation

$$x'(t) + \sum_{i=1}^{m} A_i(t)x\big(t - (H_i x)(t)\big) = f(t)$$

in $\mathbb{R}^n$ with measurable and essentially bounded functions A_i and f, and measurable delay functional H_i. Sufficient conditions are obtained for the boundedness, oscillation and nonoscillation of the solutions by using an associated linear equation.

Additional stability and oscillation results can be found in [36,46,84,92,172,173,194, 195,200,217,220,223].

9. Numerical methods

9.1. *Preliminaries*

The study of numerical approximation for state-dependent delay equations goes back at least to the mid sixties of the last century [28,77], and since then it is an intensively investigated research area [12–14,17,18,27,31,35,49,68–70,78,79,90,125,140,145,168,169,196, 197,211].

In this section we concentrate on numerical methods for state-dependent delay equations (SD-DDEs) of the form

$$x'(t) = f\big(t, x(t), x\big(t - \tau\big(t, x(t)\big)\big)\big), \quad t \in [t_0, t_N] \tag{9.1.1}$$

with an associated initial condition

$$x(t) = \phi(t), \quad t \in [t_0 - h, t_0]. \tag{9.1.2}$$

For simplicity we assume that $f : [t_0, t_N] \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous and Lipschitz continuous in its second and third variables, $\tau : [t_0, t_N] \times \mathbb{R} \to [0, h]$ is continuous, and $\phi \in C^{0,1}([t_0, t_N]; \mathbb{R})$, therefore the IVP (9.1.1)–(9.1.2) has a unique solution. The results we present can usually be easily extended to the system or multiple delays case.

We mention that there are a large number of publications dealing with other types of state-dependent differential equations including neutral SD-DDEs of the form

$$x'(t) = f\big(t, x(t), x\big(t - \tau\big(t, x(t)\big)\big), x'\big(t - \sigma\big(t, x(t)\big)\big)\big)$$

(see, e.g., [16,27,34,42,69,119,122,169,179]), the so-called "implicit" neutral SD-DDEs of the form

$$\frac{\mathrm{d}}{\mathrm{d}t}\big(x(t) - g\big(t, x\big(t - \sigma\big(t, x(t)\big)\big)\big)\big) = f\big(t, x(t), x\big(t - \tau\big(t, x(t)\big)\big)\big)$$

[102,140], Volterra differential equations with state-dependent delays [13,17,31,35,120, 196], and differential-algebraic equations with state-dependent delays [109].

9.2. *Continuous Runge–Kutta methods for ODEs*

Before we discuss approximation of state-dependent equations, first we recall some basic notations and definitions for numerical approximation of ODEs. Consider the IVP

$$x'(t) = g\big(t, x(t)\big), \quad t \in [t_0, t_N], \tag{9.2.1}$$

$$x(t_0) = x_0, \tag{9.2.2}$$

and suppose mesh points $\Delta = \{t_0 < t_1 < \cdots < t_N\}$ are given. *Discrete* one- or multistep methods associated to the IVP (9.2.1)–(9.2.2) produce a sequence $y_0, \ldots, y_N$ to approximate the solution x at the mesh points Δ. In this paper for simplicity we restrict our discussion to a popular class of one-step methods, the Runge–Kutta (RK) methods. A discrete RK method is defined by $y_0 = x_0$, and

$$y_{n+1} = y_n + h_n \sum_{i=1}^{s} b_i k_{n,i}, \quad n = 0, 1, \ldots, N-1, \tag{9.2.3}$$

where the stage values $k_{n,1}, \ldots, k_{n,s}$ are determined by the system of algebraic equations

$$k_{n,i} = g\left(t_n + h_n c_i, y_n + h_n \sum_{j=1}^{s} a_{ij} k_{n,j}\right), \quad i = 1, 2, \ldots, s, \tag{9.2.4}$$

and $h_n = t_{n+1} - t_n$. s is called the number of *stages*, the b_i's are the *weights*, the c_i's are the *abscissae* of the method satisfying $c_i \in [0, 1]$. The coefficients a_{ij} are collected in a matrix $\mathbf{A}$, the weights and abscissae in the vectors $\mathbf{b}$ and $\mathbf{c}$, and the parameters are usually listed in the Butcher tableau $\begin{array}{c|c} \mathbf{c} & \mathbf{A} \\ \hline & \mathbf{b}^{\mathrm{T}} \end{array}$. If the matrix $\mathbf{A}$ is lower triangular with zero diagonal entries then the RK method is explicit, otherwise (9.2.3) and (9.2.4) implicitly define the sequence $y_0, \ldots, y_N$.

In the mid eighties of the last century and at the beginning of the nineties the interest in the study and application of *continuous extensions* of numerical methods has been increased, since if a *dense output* is required by an ODE solver, e.g., when plotting the graph of the numerical solution, then a discrete solver is not efficient enough. Continuous methods are especially important for the approximation of delay equations where the evaluation of the approximate solution is needed in between mesh points.

One possible way to derive a continuous extension of the RK method (called CRK method) (9.2.3)–(9.2.4) is the following: Define

$$u(t_n + \theta h_n) = y_n + h_n \sum_{i=1}^{s} w_i(\theta) k_{n,i}, \quad \theta \in [0, 1],\ n = 0, 1, \ldots, N-1, \tag{9.2.5}$$

where w_i are polynomials of degree less than or equal to δ satisfying

$$w_i(0) = 0, \quad w_i(1) = b_i, \quad i = 1, \ldots, s.$$

This formula is called *interpolant of the first class* of the discrete RK method, δ is the *degree of interpolant*. The Butcher tableau of a CRK method has the form $\begin{array}{c|c} \mathbf{c} & \mathbf{A} \\ \hline & \mathbf{w}^{\mathrm{T}}(\theta) \end{array}$.

There are several methods to define the polynomial interpolation w_i in (9.2.5). A typical way is to use a cubic Hermite interpolation, or when a higher order interpolant is required, a so-called fully Hermite interpolation [71,110]. Another approach is to consider (9.2.4)–(9.2.5) as a discrete RK method with coefficients a_{ij}/θ, weights $w_i(\theta)/\theta$ and step size θh_n, and apply order conditions known for the discrete RK method, see, e.g., [27]. We mention that there are more general extensions of discrete RK methods than that of the form (9.2.5) (see, e.g., [27,110]), but we do not go into details here.

Let z be the solution of the local problem

$$z'(t) = g\bigl(t, z(t)\bigr), \quad t \in [t_n, t_{n+1}], \tag{9.2.6}$$

$$z(t_n) = z^*. \tag{9.2.7}$$

We say that the discrete RK method (9.2.3)–(9.2.4) has *order p* if $p \geqslant 1$ is the largest integer such that for all C^p-functions g in (9.2.1) and for all meshes Δ we have

$$\bigl|z(t_n) - y_n\bigr| = \mathrm{O}\bigl(h_n^{p+1}\bigr)$$

uniformly with respect to z^* in any bounded subset of $\mathbb{R}$ and $n = 0, \ldots, N-1$, where z is the solution of (9.2.6)–(9.2.7). Similarly, the CRK method (9.2.4)–(9.2.5) has *uniform order q* if $q \geqslant 1$ is the largest integer such that for all C^q-functions g in (9.2.1) and for all meshes Δ we have

$$\max\bigl\{\bigl|z(t) - u(t)\bigr|\colon t_n \leqslant t \leqslant t_{n+1}\bigr\} = \mathrm{O}\bigl(h_n^{q+1}\bigr)$$

uniformly with respect to z^* in any bounded subset of $\mathbb{R}$ and $n = 0, \ldots, N-1$, where z is the solution of (9.2.6)–(9.2.7).

We recall the following result from [27]:

THEOREM 9.2.1. *If the discrete RK method* (9.2.3)–(9.2.4) *has order p and if g is a C^p-function*, *then the method is convergent of global order p on any bounded interval* $[t_0, t_N]$, *i.e.*,

$$\max\bigl\{\bigl|x(t_n) - y_n\bigr|\colon n = 1, \ldots, N\bigr\} = \mathrm{O}\bigl(h^p\bigr),$$

where $h = \max\{h_0, \ldots, h_{N-1}\}$.

Moreover, *if the CRK method* (9.2.4)–(9.2.5) *has uniform order q*, *then it has uniform global order* $q' = \min\{p, q+1\}$, *i.e.*,

$$\max\bigl\{\bigl|x(t) - u(t)\bigr|\colon t_0 \leqslant t \leqslant t_N\bigr\} = \mathrm{O}\bigl(h^{q'}\bigr).$$

It can be checked (see [27]) that, in order to get the uniform order q, the interpolant must be of degree $\delta \geqslant q$, and if a discrete RK method has a continuous extension $u(t)$ of uniform order q with degree $\delta > q$, then it has a continuous extension $\tilde{u}(t)$ of uniform order q with degree $\delta = q$, as well.

As an example we present the Butcher tableau of a continuous extension of the classical four-stage discrete RK method which has uniform order 3:

$$\begin{array}{c|cccc} 0 & 0 & & & \\ \frac{1}{2} & \frac{1}{2} & 0 & & \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 & \\ 1 & 0 & 0 & 1 & 0 \\ \hline & w_1(\theta) & w_2(\theta) & w_3(\theta) & w_4(\theta) \end{array} \quad \text{where} \quad \begin{aligned} w_1(\theta) &= \tfrac{2}{3}\theta^3 - \tfrac{3}{2}\theta^2 + \theta, \\ w_2(\theta) &= -\tfrac{2}{3}\theta^3 + \theta^2, \\ w_3(\theta) &= -\tfrac{2}{3}\theta^3 + \theta^2, \\ w_4(\theta) &= \tfrac{2}{3}\theta^3 - \tfrac{1}{2}\theta^2. \end{aligned}$$

One-step collocation methods can be considered as CRK methods: Pick distinct abscissae $c_1, \dots, c_s \in [0, 1]$, and define

$$\begin{aligned} \ell_i(v) &= \prod_{k=1,\ k\neq i}^{s} \frac{v - c_k}{c_i - c_k}, && i = 1, \dots, s, \\ a_{ij} &= \int_0^{c_i} \ell_j(v)\,\mathrm{d}v, && i, j = 1, \dots, s, \\ w_i(\theta) &= \int_0^{\theta} \ell_i(v)\,\mathrm{d}v, && i = 1, \dots, s. \end{aligned}$$

Then the corresponding CRK method (9.2.4)–(9.2.5) defines a polynomial u of degree $\leqslant s$ satisfying the collocation equations

$$u'(t_n + h_n c_i) = g\big(t_n + h_n c_i, u(t_n + h_n c_i)\big), \quad i = 1, \dots, s, \quad u(t_n) = y_n.$$

It is known (see, e.g., [27]) that the uniform global order of this CRK method is $q' = s$ or $s + 1$.

Nowadays an efficient differential equation solver uses a higher order continuous method, or usually a pair of higher order methods (to estimate local errors in the step size selection). For other examples of CRK methods we refer to [27,49,70,71].

9.3. *The standard approach to approximation of SD-DDEs*

A typical approach (called “the standard approach” in [27]) to obtain a numerical approximation to the solution x of the state-dependent IVP (9.1.1)–(9.1.2) is the numerical analogue of the method of steps well-known for computing exact solutions of constant delay equations. In this subsection we describe this approach, but for simplicity, we formulate it using the class of one-step CRK methods. Clearly, it can be adopted using many other types of ODE discretization techniques.

Pick mesh points $\Delta = \{t_0 < t_1 < \cdots < t_N\}$, let $y_0 = \phi(t_0)$, and consider the sequence of local IVPs for $n = 0, 1, \dots, N - 1$:

$$z_n'(t) = f\big(t, z_n(t), y\big(t - \tau\big(t, z_n(t)\big)\big)\big), \quad t \in [t_n, t_{n+1}], \tag{9.3.1}$$

$$z_n(t_n) = y_n, \tag{9.3.2}$$

where

$$y(s) = \begin{cases} \phi(s), & s \in [t_0 - h, t_0], \\ u(s), & s \in [t_0, t_n], \\ z_n(s), & s \in [t_n, t_{n+1}]. \end{cases}$$

Here u denotes the function $u : [t_0, t_n] \to \mathbb{R}$ whose restriction to $[t_i, t_{i+1}]$ $(i = 0, \dots, n-1)$ is the numerical solution, i.e., a CRK interpolant of the solution of the ith IVP. Then u is already defined in the previous steps. Now we solve this IVP on $[t_n, t_{n+1}]$ using the CRK method of the form (9.2.5) corresponding to $g(t, x) = f(t, x, u(t - \tau(t, x)))$, i.e., where $k_{n,i}$'s are defined by

$$\begin{cases} t_{n,i} = t_n + h_n c_i, \\ y_{n,i} = y_n + h_n \sum_{j=1}^{s} a_{ij} k_{n,j}, \\ k_{n,i} = f\big(t_{n,i}, y_{n,i}, y\big(t_{n,i} - \tau(t_{n,i}, y_{n,i})\big)\big). \end{cases} \tag{9.3.3}$$

Then we extend u from $[t_0, t_n]$ to $[t_0, t_{n+1}]$ by this CRK interpolant, define $y_{n+1} = u(t_{n+1})$, and continue with the next local IVP in the same manner.

If τ is bounded below by a positive constant $\bar{\tau}$, and the step size is chosen so that $h_n \leqslant \bar{\tau}$, then (9.3.1) is an ODE, since y in (9.3.1) never takes an argument from $[t_n, t_{n+1}]$, so it is explicitly defined. Therefore if the discrete RK method is explicit, i.e., $\mathbf{A}$ is lower triangular with zeros in the diagonal, then its continuous extension (9.2.5)–(9.3.3) is also explicit.

The numerical difficulty arises in the *vanishing delay case*, i.e., when τ can be arbitrary small. Then h_n can be such that $t - \tau(t, z(t)) > t_n$ for some $t \in [t_n, t_{n+1}]$, so the evaluation of y in (9.3.3) depends also on the unknown interpolant u on $[t_n, t_{n+1}]$. (This is called *overlapping*.) In this case the method is implicit, even if the original discrete RK method was explicit. Therefore the existence of the numerical approximation, i.e., the solvability of the algebraic equations (9.2.4)–(9.3.3) for the stage values $k_{n,1}, \dots, k_{n,s}$ is not trivial. It can be shown [27] that the above problem has a positive answer: Suppose the functions f, τ and ϕ are Lipschitz continuous, then in the overlapping case there always exist a sufficiently small h_n and a suitable degree of interpolants so that the implicit relations (9.2.4)–(9.3.3) have a unique solution for the stage values $k_{n,1}, \dots, k_{n,s}$; therefore u has a unique extension from $[t_0, t_n]$ to $[t_n, t_{n+1}]$. The proof of this result shows that this extension can be determined as a limit of a fixed point iteration, and therefore, it is common to estimate it by iteration using a predictor–corrector method. Next we show a possible algorithm to compute the nth step of the approximation in the case when the original discrete RK method is explicit, i.e., $a_{ij} = 0$ for $i \leqslant j$ and $c_1 = 0$. In this algorithm we first (Step 1) predict a starting value of the stage values using the last computed approximate solution value in the overlapping case instead of interpolating values. If overlapping occurs, then in an iteration (Step 2) we correct the stage values. It can be done using a fixed number of steps (m in the algorithm), or by testing the numerical convergence in a loop. Finally (Step 3) we update the interpolant.

Step 1: Prediction—computation of initial stage values

```
$t_{n,1} = t_n$
$z_{n,1}^{(0)} = y_n$
$k_{n,1}^{(0)} = f\big(t_n, z_{n,1}^{(0)}, u\big(t_n - \tau\big(t_n, z_{n,1}^{(0)}\big)\big)\big)$
for $i = 2, \dots, s$ do
    $t_{n,i} = t_n + h_n c_i$
    $z_{n,i}^{(0)} = y_n + h_n \sum_{j=1}^{i-1} a_{ij} k_{n,j}^{(0)}$
    $d_{n,i}^{(0)} = t_{n,i} - \tau\big(t_{n,i}, z_{n,i}^{(0)}\big)$
    if $d_{n,i}^{(0)} \leqslant t_n$ then
        $k_{n,i}^{(0)} = f\big(t_{n,i}, z_{n,i}^{(0)}, u\big(d_{n,i}^{(0)}\big)\big)$
    else
        $k_{n,i}^{(0)} = f\big(t_{n,i}, z_{n,i}^{(0)}, z_{n,i}^{(0)}\big)$
    end if
end for
```

Step 2: Correction by iteration is needed if $d_{n,i}^{(0)} > t_n$ was for any $i \geqslant 2$ in Step 1

```
for $r = 1, \dots, m$ do
    for $i = 1, \dots, s$ do
        $z_{n,i}^{(r)} = y_n + h_n \sum_{j=1}^{i-1} a_{ij} k_{n,j}^{(r-1)}$
        $d_{n,i}^{(r)} = t_{n,i} - \tau\big(t_{n,i}, z_{n,i}^{(r-1)}\big)$
        if $d_{n,i}^{(r)} \leqslant t_n$ then
            $k_{n,i}^{(r)} = f\big(t_{n,i}, z_{n,i}^{(r)}, u\big(d_{n,i}^{(r)}\big)\big)$
        else
            $\theta_i = \dfrac{d_{n,i}^{(r)} - t_n}{h_n}$
            $\hat{u}_i = y_n + h_n \sum_{j=1}^{i-1} w_j(\theta_i) k_{n,j}^{(r)} + h_n \sum_{j=i}^{s} w_j(\theta_i) k_{n,j}^{(r-1)}$
            $k_{n,i}^{(r)} = f\big(t_{n,i}, z_{n,i}^{(r)}, \hat{u}_i\big)$
        end if
    end for
end for
```

Step 3: Computation of the extension of u to $[t_n, t_{n+1}]$

$$u(t_n + \theta h_n) = y_n + h_n \sum_{i=1}^{s} w_i(\theta) k_{n,i}^{(m)}, \quad \theta \in [0, 1].$$

Most modern differential equation solvers use non-uniform mesh size, therefore the selection of the step size in each integration step (the so-called *primary step size selection*) is an important practical issue in such softwares. Concerning this topic we refer to [27,110,125] for more details.

The next result says that in order a method be of order p it is necessary that the solution be at least C^p on each interval $[t_n, t_{n+1}]$. We say that the function x has *discontinuity of order* p at ξ if $x^{(p-1)}$ exists and is continuous at ξ, and $x^{(p)}$ has jump discontinuity at ξ, i.e., $x^{(p)}(\xi+) \neq x^{(p)}(\xi-)$.

For the proof of the next result see [27]:

THEOREM 9.3.1. *Suppose f, τ and ϕ are C^p functions. Moreover,*

(1) *the mesh $\Delta = \{t_0 < t_1 < \cdots < t_N\}$ includes all discontinuity points $\xi_1 < \xi_2 < \cdots < \xi_m$ of the solution of order $\leqslant p$;*

(2) *the discrete RK method* (9.2.1)–(9.2.3) *is consistent of order p and the CRK method* (9.2.4)–(9.2.5) *is consistent of uniform order q.*

Then the method (9.2.4)–(9.3.3) *for solving the IVP* (9.1.1)–(9.1.2) *is convergent of uniform global order $q' = \min\{p, q+1\}$, i.e.*

$$\max\big\{\big|x(t) - u(t)\big|\colon t_0 \leqslant t \leqslant t_N\big\} = \mathrm{O}\big(h^{q'}\big),$$

where $h = \max\{h_0, \ldots, h_{N-1}\}$.

We note that there are many papers which follow the basic method of steps described in this subsection, i.e., approximate the solution of an SD-DDE by that of an ODE, but defined by different discrete or continuous one- or multistep ODE solvers or with different definitions of the associated ODE [15,49,68,70,77,91,124,125,169,179].

Rewriting a constant delay equation as an equivalent abstract Cauchy problem and using Trotter–Kato-type approximations is another popular approach especially in control applications. This technique was extended to SD-DDEs in [118].

9.4. *Tracking of derivative discontinuities*

Theorem 9.3.1 indicates that a high order method must locate all the discontinuity points of the solutions up to order p, and add them to the mesh. For constant or time-dependent delay equations this is a relatively simple task, but in the state-dependent delay case it leads to significant difficulties. Indeed, the location of the discontinuity points can not be computed *a priori* because they depend on the solution, and, on the other hand, only approximate locations can be computed.

We assume throughout this subsection that f, τ and ϕ are all C^p-functions. One can show that in case $\phi'(t_0-) \neq f(t_0, \phi(t_0), \phi(-\tau(t_0)))$ the corresponding solution x of the IVP (9.1.1)–(9.1.2) has discontinuity of order 1 at $t = t_0$, but for $t > t_0$ the solution is $C1$-smooth. If $\xi > t_0$ is such that $\xi - \tau(\xi, x(\xi)) = t_0$, it is easy to check that $x''(\xi-) \neq x''(\xi+)$, so x has a discontinuity of order 2 at $t = \xi$. Similarly, if we set $\xi_0 = t_0$ and define a (finite or infinite) sequence by the relation $\xi_{i+1} - \tau(\xi_{i+1}, x(\xi_{i+1})) = \xi_i$ for $i = 0, 1, \ldots,$ the sequence $\xi_0, \xi_1, \ldots$ consists of discontinuity points of increasing order: ξ_i has order $i + 1$. If a solution x is such that the time lag function $t \mapsto t - \tau(t, x(t))$ is strictly monotone increasing (which is satisfied in many applications), the above sequence will contain all discontinuity points of the solution.

On the other hand, if the above time lag function is not strictly monotone increasing, then the equation $\xi - \tau(\xi, x(\xi)) = \xi_i$ may have many solutions ξ. It can be checked (see [27,78,79,168]) that at a solution ξ of the above equation the function x has a discontinuity of order $\geqslant 1$, if and only if the graph of $t \mapsto t - \tau(t, x(t))$ crosses the level ξ_i, i.e., the root ξ has odd multiplicity. Therefore in this case the discontinuity points can be naturally stored in a tree: $\xi_{0,1} = t_0$ is the root of the tree, level 1 of the tree contains the solutions $\xi_{1,1}, \ldots, \xi_{1,\ell_1}$ of

$$\xi - \tau\big(\xi, x(\xi)\big) = \xi_{i,j} \tag{9.4.1}$$

with odd multiplicity for $i = 0$ and $j = 1$. Then for $i = 1$ and any $j = 1, \ldots, \ell_1$ the solutions $\xi_{2,1}, \ldots, \xi_{2,\ell_2}$ of (9.4.1), if exist, are placed in the second level of the tree, as the descendents of the respective $\xi_{1,j}$, etc.

It was shown in [168] that there are only finitely many computationally important points (i.e., of order less or equal to p) in the discontinuity propagation tree, so they can be ordered and relabeled as an increasing sequence $t_0 = \xi_0 < \xi_1 < \xi_2 < \cdots < \xi_\ell \leqslant t_N$. In the sequel we use this notation.

Let ξ_j be a descendent of ξ_i in the discontinuity tree, i.e.,

$$\xi_j - \tau\big(\xi_j, x(\xi_j)\big) = \xi_i. \tag{9.4.2}$$

It is easy to see that as discontinuity propagates from ξ_i to ξ_j, smoothing occurs. More precisely, we recall the next result from [168].

THEOREM 9.4.1. *Suppose ξ_i and ξ_j satisfying* (9.4.2) *are discontinuity points of order k_i and k_j, respectively, and ξ_j has odd multiplicity m_j. Then $m_j k_i + 1 \leqslant k_j$.*

Since the exact discontinuity points $\xi_1, \dots, \xi_\ell$ depend on the solution, suitable approximations are required. Let u denote the continuous interpolant (in the previous subsection it was a CRK interpolant) of the numerical approximation of x using certain mesh and approximate values $y_0 = \phi(t_0), y_1, \dots, y_N$. Let $\tilde{\xi}_0 = t_0$, and define the approximate discontinuity points as solutions of

$$\xi - \tau\bigl(\xi, u(\xi)\bigr) = \tilde{\xi}_i \tag{9.4.3}$$

where u is the approximate solution of the IVP satisfying $|x(\tilde{\xi}_j) - u(\tilde{\xi}_j)| = \mathrm{O}(h^p)$, and $h = \max\{h_0, \dots, h_{N-1}\}$. The following result is cited from [78]:

THEOREM 9.4.2. *Let u be a pth order approximation of x at $\tilde{\xi}_j$, i.e., $|x(\tilde{\xi}_j) - u(\tilde{\xi}_j)| = \mathrm{O}(h^p)$, $h = \max\{h_0, \dots, h_{N-1}\}$, m_j be the multiplicity of ξ_j in* (9.4.2), *and $|\xi_i - \tilde{\xi}_i| = \mathrm{O}(h^{r_i})$. Then $|\xi_j - \tilde{\xi}_j| = \mathrm{O}(h^{r_j})$ where $r_j = \min\{p, r_i\}/m_j$.*

Feldstein and Neves [78] suggested the following *secondary step size control* to select the step size of the numerical integration method so that the approximate discontinuity points are collected to the mesh to keep the global order of the method high: Suppose at the nth step $y_0, \dots, y_n$ are defined, and the approximate discontinuity points found so far are $t_0 = \tilde{\xi}_0 < \tilde{\xi}_1 < \tilde{\xi}_2 < \cdots < \tilde{\xi}_{\ell_n} \leqslant t_N$.

Step 1: Predict the next approximate value of the integration method by $y_{n+1} = u(t_n + h_n)$ using the continuous method u of order p and the step size h_n selected by the primary step size control method of u.

Step 2: For $i = 1, \dots, \ell_n$ find the first i such that

$$\bigl(t_n - \tau(t_n, y_n) - \tilde{\xi}_i\bigr)\bigl(t_{n+1} - \tau(t_{n+1}, y_{n+1}) - \tilde{\xi}_i\bigr) < 0,$$

i.e., (9.4.3) corresponding to the right-hand side $\tilde{\xi}_i$ has a solution $\tilde{\xi}$. If such i exists then proceed with Step 3, otherwise we accept h_n and y_{n+1} and finish this algorithm, i.e, go to the next iterate of computing y_{n+2}.

Step 3: Using a root-finding method (e.g., bisection) combined with the definition of u find an approximate solution $\tilde{\xi}$ with the above property (if more solutions are found, the least one is used).

Step 4: Include $\tilde{\xi}$ to the new mesh $\hat{t}_0 = t_0, \dots, \hat{t}_n = t_n, \hat{t}_{n+1} = \tilde{\xi}, \hat{t}_{n+2} = t_{n+1}$, redefine the approximate solution values $\hat{y}_0 = y_0, \dots, \hat{y}_n = y_n, \hat{y}_{n+1} = u(\tilde{\xi})$. Restart the numerical integration from $\hat{t}_{n+1} = \tilde{\xi}$ to $\hat{t}_{n+2}$. Let $\hat{u}$ be the new interpolant on $[\hat{t}_{n+1}, t_{n+2}]$, and define $\hat{y}_{n+2} = \hat{u}(t_{n+2})$.

Step 5: Continue with the next iterate.

See [78,79] for more details. Concerning the global order of the above method combined with a pth order continuous numerical approximation method u Feldstein and Neves [78] showed:

THEOREM 9.4.3. *Suppose the order of discontinuity of ξ_j is k_j $(j = 1, \dots, \ell)$, $\tilde{\xi}_j$ is the corresponding approximate discontinuity point, i.e., the solution of* (9.4.3), $|\xi_j - \tilde{\xi}_j| =$

$\mathrm{O}(h^{r_j})$, $\hat{\xi}_j$ is a numerical approximation of $\tilde{\xi}_j$ with order $|\hat{\xi}_j - \tilde{\xi}_j| = \mathrm{O}(h^{s_j})$, and the uniform order of u is p. Then

$$\max\{|x(t) - u(t)|\colon t \in [t_0, t_N]\} = \mathrm{O}(h^s) \quad \textit{where } s = \min_{j=1,\dots,\ell}\{p, k_j r_j, k_j s_j\}.$$

Moreover, if $s_j \geqslant p/k_j$ for $j = 1, \dots, \ell$, then

$$\max\{|x(t) - u(t)|\colon t \in [t_0, t_N]\} = \mathrm{O}(h^p).$$

In this subsection we assumed that the parameters of the IVP, f, τ and ϕ are all C^p-functions. If they are only piecewise C^p-functions, i.e., there are points where any of the tree parameters has smaller smoothness, then starting from such a point we can build a discontinuity propagation tree similar to what we described in this subsection. Such points are called *secondary discontinuity points*. Similarly, multiple delays can also be handled (see, e.g., [27]).

We note that the extension of the notion of the discontinuity tree from the scalar case to the system case is far from being obvious, and was investigated by Willé and Baker [212, 213]. They associated a so called dependency network of oriented graphs to the discontinuity points, see also [27]. For more discussions on numerical problems related to tracking discontinuity points we refer to [211,214].

Tracking discontinuities can be computationally expensive, especially when the number of discontinuity points is large. Another typical approach to handle the loss of numerical accuracy due to the presence of derivative discontinuities is the method of *defect control* developed by Enright and Hayashi [67,69] (see also [16,79]). In this method the size of the defect, i.e., $\max\{|u'(t) - f(t, u(t), u(t - \tau(t, u(t))))|\colon t \in [t_n, t_{n+1}]\}$ is monitored and its size is controlled at each step of the integration.

9.5. *Concluding remarks*

There are several software packages available for solving SD-DDEs. Without completeness we list some of them: ARCHI (Paul [179]), DDE-STRIDEL (Butcher [34]), DDVERK (Enright and Hayashi [68]), DMRODE (Neves [167]), DKLAG6 (Corwin, Sarafyan and Thompson [49]), RADAR5 (Guglielmi and Hairer [90]), SNDDELM (Jackiewicz and Lo [122]), SYSDEL (Karouri and Vaillancourt [125]). We refer to [27,79,197] for further discussion and comparison of available solvers for state-dependent delay equations.

In this section we discussed some problems related to the design and analysis of numerical approximation schemes for state-dependent delay equations. Other important qualitative issues, like stability of numerical methods are not discussed here, we mention [12, 27,140] for studies in this directions. We also mention that there are many topics beyond the scope of this survey, e.g., numerical bifurcation analysis (see [66,145]), boundary value problems (see [18]) or parameter estimation (see [14,100,103,107,164]) for state-dependent delay equations.

1. Introduction

We consider solutions of the two point boundary value problems

$$u''(x)+\lambda f\big(x,u(x)\big)=0 \quad \text{for } a<x<b, \qquad u(a)=u(b)=0, \tag{1.1}$$

depending on a parameter λ. We wish to know how many *exactly* solutions does problem (1.1) have, and how these solutions change with λ. What is the role of the parameter λ? Of course, it could be absorbed into the nonlinearity f. However, as is often the case, it is helpful to have something "extra" in the statement of the problem. Consider for example the problem

$$u''(x)+4\mathrm{e}^{\frac{5u(x)}{5+u(x)}}=0 \quad \text{for } 0<x<1, \qquad u(0)=u(1)=0. \tag{1.2}$$

Problems of this type come up in combustion theory, referred to as "perturbed Gelfand problem", see, e.g., J. Bebernes and D. Eberly [7]. It will follow from a result we present below that this problem has *exactly* three positive solutions. It appears next to impossible to establish this result directly. We introduce a parameter λ, and consider

$$u''(x)+\lambda\mathrm{e}^{\frac{5u(x)}{5+u(x)}}=0 \quad \text{for } 0<x<1, \qquad u(0)=u(1)=0. \tag{1.3}$$

We now study *curves of solutions*, $u=u(x,\lambda)$. The advantage of this approach is that some parts of the solution curve are easy to understand, and it also becomes clear what are the tougher parts of the solution curve that we need to study—the *turning points*. For example, it is easy to understand the "small" solutions of (1.3), by applying the implicit function theorem (in Banach spaces) in the neighborhood of the trivial solution $\lambda=0$, $u=0$. We then continue this curve of solutions for increasing $\lambda>0$ until a critical solution is reached, i.e. the implicit function theorem is no longer applicable. We show that at the critical solution the Crandall–Rabinowitz Theorem 1.2 (see below) applies. It implies that either the solution curve continues forward in λ through the critical solution, or it just bends back (no secondary bifurcations or other eccentric behaviour is possible). We then show that the global solution curve makes exactly two turns, and the value of $\lambda=4$ from (1.2) lies between the turns, thus establishing the existence of three solutions. The bifurcation approach, just described, has been developed in the recent years by Y. Li, T. Ouyang, J. Shi and the present author. It applies also to the semilinear elliptic problems for balls in $\mathbb{R}^n$, however in the present paper we restrict to the ODE case (1.1).

The most detailed results are obtained when one considers positive solutions of autonomous problems, i.e. when $f=f(u)$. Since in that case both the length and the position of the interval (a,b) are irrelevant, and since positive solutions are symmetric with respect to the midpoint of the interval, it is convenient to pose the problem on the interval $(-1,1)$, i.e. we consider

$$u''(x)+\lambda f\big(u(x)\big)=0 \quad \text{for } -1<x<1, \qquad u(-1)=u(1)=0. \tag{1.4}$$

It turns out that convexity properties of $f(u)$ are important for determining the direction of the turn for solution curves. Accordingly, in the simplest case $f''(u) > 0$ and $f(u) > 0$, for $u > 0$, we can give an exhaustive analysis of the problem. (In case $f''(u) < 0$ and $f(u) > 0$, for $u > 0$, it is easy to prove uniqueness of solutions.) The next case in order of complexity is when $f(u)$ changes concavity exactly once. The prominent case is when $f(u)$ is modelled on a cubic with simple roots:

$$u'' + \lambda(u-a)(u-b)(c-u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0. \tag{1.5}$$

We assume that $0 \leqslant a < b < c$, since the analysis is easier if some root(s) is negative. We wish to describe how many *exactly* positive solutions does problem (1.5) have for various λ.

This problem was studied in a 1981 paper by J. Smoller and A. Wasserman [57]. They succeeded in solving the problem for $a = 0$, while their proof for $a > 0$ case contained an error. This error was discovered by S.-H. Wang [59], who was able to solve the problem under some restriction on $a > 0$. Both papers used the phase-plane analysis. Then P. Korman, Y. Li and T. Ouyang [30] used bifurcation theory to attack the problem, but again some restrictions were necessary (all of the above mentioned papers covered more general $f(u)$, behaving like cubic). Very recently, P. Korman, Y. Li and T. Ouyang [33], building on their previous work, have given a computer assisted proof for general cubic. It turns out that the set of all positive solutions consists of two curves, with the lower curve monotone in λ, and the upper curve having exactly one turn. The computations in P. Korman, Y. Li and T. Ouyang [30] also showed that the approach in J. Smoller and A. Wasserman [57] could not possibly cover the general cubic. (That approach required a certain integral to be positive, in order to derive a differential inequality for a time map. However, that integral changes sign for some cubics.) In the next section we state the optimal result, and describe the approach taken in [30] and [33].

Another prominent class of problems where $f(u)$ changes concavity exactly once is

$$u'' + \lambda e^{\frac{au}{u+a}} = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{1.6}$$

from combustion theory. Here a is a second parameter. In case $a = 5$, we have the problem (1.3), discussed above. If $a \leqslant 4$, the problem is easy. In that case the solution curve is monotone, and it continues for all $\lambda > 0$ without any turns. Following some earlier results of K.J. Brown, M.M.A. Ibrahim and R. Shivaji [9] and others (see [60] and [29] for the earlier references), S.-H. Wang [60] has proved existence of a constant a_0, so that for $a > a_0$ the solution curve of (2.21) is exactly S-shaped, i.e. it starts at $\lambda = 0$, $u = 0$, it makes exactly two turns, and then it continues for all $\lambda > 0$ without any more turns. S.-H. Wang [60] gave an approximation of the constant $a_0 \simeq 4.4967$. That paper, as well as all previous ones, used a time map approach. P. Korman and Y. Li [29] have applied the bifurcation approach to the problem. Since bifurcation approach is more general, this opened a way to do other problems. In fact, Y. Du and Y. Lou [14] have used a similar approach, with several additional tricks of their own, to prove that for a ball in two dimensions a similar result holds for sufficiently large a.

P. Korman and Y. Li [29] had also improved the value of the constant to $a_0 \simeq 4.35$, i.e. for $a > a_0$ the solution sets are S-shaped curves. But what about $4 < a < a_0$? S.-H. Wang [60] has conjectured existence of a critical number $\bar{a}$, so that for $a \leqslant \bar{a}$ the solution curve is monotone, while for $a > \bar{a}$ the solution curve is exactly S-shaped (the number a_0, mentioned above, is just an upper bound for $\bar{a}$). Recently, P. Korman, Y. Li and T. Ouyang [33] has given a computer assisted proof of the S.-H. Wang's conjecture. Numerical calculations show that $\bar{a} \simeq 4.07$.

Other topics we discuss using the bifurcation approach involve pitchfork bifurcation and symmetry breaking, sign changing solutions, and the Neumann problem. We also present a recent formula from P. Korman, Y. Li and T. Ouyang [33], which allows one to compute all possible values of $\alpha = u(0)$, at which solution of (1.4), with the maximal value equal to α, is singular.

The case when $f = f(x,u)$ is much harder than the autonomous case. In particular, the time map method does not apply. Bifurcation approach works, but it becomes much more complicated. For example, solutions of the corresponding linearized problem need not be of one sign (an implicit example of that is provided by the Theorem 1.10 in W.-M. Ni and R.D. Nussbaum [46]). In the papers P. Korman and T. Ouyang a class of $f(x,u)$ has been identified, for which the theory of positive solutions is very similar to that for the autonomous case, see, e.g., [34–36]. Further results in this direction have been given in P. Korman, Y. Li and T. Ouyang [30], and P. Korman and J. Shi [40]. Namely, assume that $f \in C^2$ satisfies

$$f(-x,u) = f(x,u) \quad \text{for all } -1 < x < 1 \text{ and } u > 0,$$

$$f_x(x,u) \leqslant 0 \quad \text{for all } 0 < x < 1 \text{ and } u > 0.$$

Under the above conditions any positive solution of (1.1) is an even function, with $u'(x) < 0$ for all $x \in (0,1]$, see B. Gidas, W.-M. Ni and L. Nirenberg [15]. We show that any solution of the corresponding linearized problem is of one sign, and then outline a number of exact multiplicity results.

Without symmetry assumption on $f(x,u)$ things are even more hard. In Section 4 we present extensions of the previous results in P. Korman and T. Ouyang [38]. The notion of Schwarzian derivative from Complex Analysis turns out to play a role here.

The bifurcation approach is effective for other problems, in addition to the two point problems that we discuss in the present paper. Most notably, similar results were developed for PDE's on a ball or annulus in $\mathbb{R}^n$, see, e.g., P. Korman, Y. Li and T. Ouyang [31] or T. Ouyang and J. Shi [50]. It was also used for systems of equations in P. Korman [22], for fourth order equations in P. Korman [26], and for periodic problems in P. Korman and T. Ouyang [37].

In Section 5 we give a brief review of time map method. Let $u = u(t)$ be solution of the initial value problem,

$$u'' + f(u) = 0, \qquad u(0) = 0, \quad u'(0) = p.$$

Using ballistic analogy, we can interpret this as "shooting" from the ground level, at an angle $p > 0$. Let $T/2$ denote the time it takes for the projectile to reach its maximum amplitude. By symmetry of positive solutions, $T = T(p)$ is then the time when the projectile falls back to the ground, the *time map*. The function $u(t)$ then satisfies the two point Dirichlet problem

$$u'' + f(u) = 0 \quad \text{for } 0 < t < T, \qquad u(0) = u(T) = 0,$$

which by rescaling is equivalent to (1.4). There are two completely different formulas for the same time map $T = T(p)$. The first one is obtained by direct integration, see, e.g., W.S. Loud [43] for an early reference, while the second one was derived by R. Schaaf [53] through a change of variables, which converts the problem into a harmonic oscillator. Both formulas for the time map are nontrivial to use. The first one involves improper integrals, while the second one is highly implicit. ("Name your poison", so to say.) However, both approaches are well developed by now, see the book by R. Schaaf [53], and the papers of S.-H. Wang and his coworkers, of I. Addou, and many other papers, including J. Cheng [10,11], and K.J. Brown et al. [9]. We give an exposition of the second approach, and connect it to the notion of *generalized averages* from P. Korman and Y. Li [28].

In the final Section 6 we discuss numerical computation of solutions of (1.4). Again, the autonomous case is much easier. We describe two efficient ways to compute the solutions, and explain why finite differences (or finite elements) are not appropriate for autonomous problems.

The basic tool for continuation of solutions is the implicit function theorem in Banach spaces. We present it here in the formulation of M.G. Crandall and P.H. Rabinowitz [12], see also L. Nirenberg [45], and A. Ambrosetti and G. Prodi [5].

THEOREM 1.1. *Let X, Λ and Z be Banach spaces, and $f(x, \lambda)$ a continuous mapping of an open set $U \subset X \times \Lambda \to Z$. Assume that f has a Frechet derivative with respect to x, $f_x(x, \lambda)$ which is continuous on U. Assume that*

$$f(x_0, \lambda_0) = 0 \quad \textit{for some } (x_0, \lambda_0) \in U.$$

If $f_x(x_0, \lambda_0)$ is an isomorphism (i.e. $1:1$ and onto) of X onto Z, then there is a ball $B_r(\lambda_0) = \{\lambda \colon \|\lambda - \lambda_0\| < r\}$ and a unique continuous map $x(\lambda) : B_r(\lambda_0) \to X$, such that

$$f\big(x(\lambda), \lambda\big) \equiv 0, \quad x(\lambda_0) = x_0.$$

If f is of class C^p, so is $x(\lambda)$, $p \geqslant 1$.

In the conditions of the above theorem, we refer to (x_0, λ_0) as a regular solution, otherwise we call a solution singular. What happens at a singular solution? (I.e. when $f_x(x_0, \lambda_0)$ is not an isomorphism.) In general, practically anything imaginable may happen, as one can see even for functions of two variables. However, in a lucky case solution will continue through a critical point, either by making a simple turn there, or maybe it even continues forward in λ (the critical point is then like a point of inflection). M.G. Crandall and P.H. Rabinowitz [13] have given conditions for that to occur. The following result is one of our principal tools.

THEOREM 1.2. [13] *Let X and Y be Banach spaces. Let $(\overline{\lambda}, \overline{x}) \in \mathbb{R} \times X$ and let F be a continuously differentiable mapping of an open neighborhood of $(\overline{\lambda}, \overline{x})$ into Y. Let the null-space $N(F_x(\overline{\lambda}, \overline{x})) = \operatorname{span} x_0$ be one-dimensional and* $\operatorname{codim} R(F_x(\overline{\lambda}, \overline{x})) = 1$. *Let $F_\lambda(\overline{\lambda}, \overline{x}) \notin R(F_x(\overline{\lambda}, \overline{x}))$. If Z is a complement of $\operatorname{span} x_0$ in X, then the solutions of $F(\lambda, x) = F(\overline{\lambda}, \overline{x})$ near $(\overline{\lambda}, \overline{x})$ form a curve $(\lambda(s), x(s)) = (\overline{\lambda} + \tau(s), \overline{x} + s x_0 + z(s))$, where $s \to (\tau(s), z(s)) \in \mathbb{R} \times Z$ is a continuously differentiable function near $s = 0$ and* $\tau(0) = \tau'(0) = 0$, $z(0) = z'(0) = 0$.

Except for a brief discussion on p-Laplace equations, we consider only the classical solutions throughout this paper. We shall denote the derivatives of $u(x)$ by either $u'(x)$ or u_x, and mix both notations sometimes to make our discussion more transparent.

Most of the results in the present paper are based on our joint papers with Y. Li, T. Ouyang and J. Shi. Working with these talented colleagues has been a wonderful experience for me, and I wish to thank them for this opportunity. I also wish to thank Professors A. Canada, P. Drabek and A. Fonda for inviting me to write this review paper.

2. Bifurcation theory approach

2.1. *Some general properties of solutions of autonomous problems*

We will consider positive, negative and sign-changing solutions of the Dirichlet problem (for $u = u(x)$)

$$u'' + \lambda f(u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{2.1}$$

depending on a parameter λ. We assume throughout this section that $f(u) \in C^2(\overline{\mathbb{R}}_+)$. We choose to consider the problem on the interval $(-1, 1)$ for convenience (which is related to the symmetry of solutions). By shifting and scaling, we can replace the interval $(-1, 1)$ by any other interval (a, b).

LEMMA 2.1. *Let $\xi \in (-1, 1)$ be any critical point of $u(x)$, i.e. $u'(\xi) = 0$. Then $u(x)$ is symmetric with respect to ξ.*

PROOF. Let $v(x) \equiv u(2\xi - x)$. Then $v(x)$ satisfies the same equation (2.1), and, moreover, $v(\xi) = u(\xi)$ and $v'(\xi) = u'(\xi) = 0$. By uniqueness of initial value problems, $u(x) \equiv v(x)$, and the proof follows. □

LEMMA 2.2. *Solution of* (2.1) *cannot have points of positive minimum, and of negative maximum.*

PROOF. Let us rule out the case of positive minimums, with the other case being similar. Assume on the contrary that there are points of positive minimums, and let ξ be the largest such point. Since $u(\xi) > 0$ and $u(1) = 0$, we can find a point $\eta \in (\xi, 1)$, so that $u(\xi) = u(\eta)$. Observe that $u'(\eta) < 0$. Indeed, if we had $u'(\eta) = 0$, then by the preceding lemma,

η would have to be a point of minimum, contradicting the maximality of ξ. We know that the energy $E(x) = \frac{1}{2}u'(x)^2 + \lambda F(u(x))$ is constant, but by above, $E(\eta) > E(\xi)$, a contradiction. ☐

We now consider positive solutions of (2.1). It follows from the lemmas above, that any positive solution is an even function, with $u'(x) > 0$ on $(-1, 0)$, and $u'(x) < 0$ on $(0, 1)$. (Of course, by the classical theorem of B. Gidas, W.-M. Ni and L. Nirenberg [15] this result holds for balls in $\mathbb{R}^n$ for any $n \geqslant 1$.) Hence $\alpha \equiv u(0)$ is the maximal value of solution. We show next that it is impossible for two solutions of (2.1) to share the same α.

LEMMA 2.3. *The value of $u(0) = \alpha$ uniquely identifies the solution pair $(\lambda, u(x))$ (i.e. there is at most one λ, with at most one solution $u(x)$, so that $u(0) = \alpha$).*

PROOF. Assume on the contrary that we have two solution pairs $(\lambda, u(x))$ and $(\mu, v(x))$, with $u(0) = v(0) = \alpha$. Clearly, $\lambda \neq \mu$, since otherwise we have a contradiction with uniqueness of initial value problems. (Recall that $u'(0) = v'(0) = 0$.) Then $u(\frac{1}{\sqrt{\lambda}}x)$ and $v(\frac{1}{\sqrt{\mu}}x)$ are both solutions of the same initial value problem

$$u'' + f(u) = 0, \qquad u(0) = \alpha, \quad u'(0) = 0,$$

and hence $u(\frac{1}{\sqrt{\lambda}}x) \equiv v(\frac{1}{\sqrt{\mu}}x)$, but that is impossible, since the first function vanishes at $x = \sqrt{\lambda}$, while the second one at $x = \sqrt{\mu}$. ☐

Bifurcation theory approach revolves around the study of the linearized equation for (2.1)

$$w'' + \lambda f'\bigl(u(x)\bigr)w = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0, \tag{2.2}$$

where $u(x)$ is a solution of (2.1). If this problem has a nontrivial solution, we call $u(x)$ a singular solution of (2.1). We say that the solution $u(x)$ is nonsingular, if $w(x) \equiv 0$ is the only solution of (2.2). The following lemma is easy to prove in the autonomous case.

LEMMA 2.4. *Let $u(x)$ be a positive solution of* (2.1), *with*

$$u'(1) < 0. \tag{2.3}$$

If the problem (2.2) *admits a nontrivial solution, then it does not change sign, i.e. we may assume that $w(x) > 0$ on* $(-1, 1)$.

PROOF. The function $u'(x)$ also satisfies the linear equation (2.2). By the condition (2.3), $u'(x)$ is not a multiple of $w(x)$. Hence its roots are interlaced with those of $w(x)$. If $w(x)$ had a root ξ inside say $(-1, 0)$, then $u'(x)$ would have to vanish on $(-1, \xi)$, which is impossible by the remarks following Lemma 2.2. ☐

Condition (2.3) will hold for any positive solution, provided that

$$f(0) \geqslant 0, \tag{2.4}$$

see, e.g., p. 107 in M. Renardi and R.C. Rogers [52]. If $f(0) < 0$ it is possible to have $u'(1) = 0$. We shall encounter such a situation later, in connection with symmetry-breaking bifurcation. What we see here is a manifestation of the "divide" between the problems when (2.4) holds, and the case of $f(0) < 0$.

LEMMA 2.5. *If problem* (2.2) *admits nontrivial solutions, then the solution set is one dimensional. If moreover $u(x)$ is a positive solution, satisfying* (2.3), *then $w(x)$ is an even function.*

PROOF. By uniqueness of initial value problem the value of $w'(1)$ uniquely determines $w(x)$, and hence the null space is one dimensional. Turning to the second claim, if $u(x)$ is positive, then it is even. Hence $w(-x)$ also solves (2.2). Since the null space is one dimensional, $w(-x) = cw(x)$ for some constant c. Evaluating this relation at $x = 0$, we conclude that $c = 1$ (since $w(0) > 0$ by the previous lemma), which is the desired symmetry. ☐

The following lemma gives a simple condition for positive solutions of (2.1) to be nonsingular.

LEMMA 2.6. *Assume that either*

$$f'(u) > \frac{f(u)}{u} \quad \textit{for all } u > 0,$$

or the opposite inequality holds. Then the linearized problem (2.2) *has only the trivial solution.*

PROOF. If we rewrite Eq. (2.1) in the form

$$u'' + \lambda \frac{f(u)}{u} u = 0,$$

and use the Sturm comparison theorem, we conclude that the positive solution $u(x)$ oscillates faster than $w(x)$, and hence it must vanish on $(-1, 1)$, which is impossible. ☐

Another very simple condition is the following.

LEMMA 2.7. *Assume that*

$$f'(u) < 0 \quad \textit{for all } u > 0.$$

Then the linearized problem (2.2) *has only the trivial solution.*

PROOF. Multiplying Eq. (2.2) by w, and integrating, we conclude that problem (2.2) can have only the trivial solution. □

We shall need the following lemma, which "connects" the solutions of (2.1) and (2.2). It will allow us to verify the crucial condition of the Crandall–Rabinowitz Theorem 1.1 for both positive and sign changing solutions.

LEMMA 2.8. *If problem* (2.2) *admits a nontrivial solution*, *then*

$$\int_{-1}^{1} f(u)w \, dx = \frac{1}{\lambda} u'(1)w'(1). \tag{2.5}$$

PROOF. The quantity $u''(x)w(x) - u'(x)w'(x)$ is a constant, and hence

$$u''(x)w(x) - u'(x)w'(x) = -u'(1)w'(1).$$

Integrating over $(-1, 1)$ (by parts), we conclude the lemma. □

Very often one is looking for positive solutions of (2.1). A possible reason for this emphasis, is that only positive solutions have a chance to be stable, a property significant for applications. Let us recall the notion of stability. For any solution $u(x)$ of (2.1) let $(\mu, w(x))$ denote the principal eigenpair of the corresponding linearized equation, i.e. $w(x) > 0$ satisfies

$$w'' + \lambda f'(u)w + \mu w = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0. \tag{2.6}$$

The solution $u(x)$ of (2.1) is called unstable if $\mu < 0$, it is called stable if $\mu > 0$, and neutrally stable in case $M = 0$. (This is so-called linear stability. It means, roughly, that solutions of the corresponding heat equation, with the initial data near $u(x)$ will tend to $u(x)$, as $t \to \infty$, see the book by D. Henry [16].)

PROPOSITION 1. *Let* $u(x)$ *be a solution of* (2.1) *that changes sign on* $(-1, 1)$. *Then* $u(x)$ *is unstable.*

PROOF. Let $(\mu, w(x))$ denote the principal eigenpair of (2.6). Assume that on the contrary $\mu \geqslant 0$. Since $u(x)$ changes sign, we can find $-1 < x_1 < x_2 < 1$, such that $u'(x_1) = u'(x_2) = 0$ and say $u'(x) < 0$ on (x_1, x_2) (the other case is similar). Observe that $u''(x_1) < 0$ and $u''(x_2) > 0$ ($u'(x)$ satisfies a linear equation, it cannot vanish together with its derivative). Denoting $p(x) = u''(x)w(x) - u'(x)w'(x)$, we have

$$p'(x) = \mu u'(x)w(x) \leqslant 0 \quad \text{for } x \in (x_1, x_2).$$

We see that $p(x)$ is nonincreasing on (x_1, x_2). But, $p(x_1) = u''(x_1)w(x_1) < 0$ and $p(x_2) = u''(x_2)w(x_2) > 0$, a contradiction. □

This result was also proved by R. Schaaf [53]. A similar result for balls in $\mathbb{R}^n$ can be found in C.S. Lin and W.-M. Ni [42].

LEMMA 2.9. *Any two positive solutions of* (2.1) *do not intersect inside* $(-1,1)$ (*i.e. they are strictly ordered on* $(-1,1)$).

PROOF. Let $u(x)$ and $v(x)$ be two intersecting solutions. Since both of them are even functions, they intersect on the half-interval $(0,1)$ as well. Let $0<\xi<\eta<1$ be two consecutive intersection points. If $v(x)>u(x)$ on (ξ,η), then $|u'(\xi)|>|v'(\xi)|$, while $|u'(\eta)|<|v'(\eta)|$. The energy $E(x)=\frac{1}{2}u'(x)^2+\lambda F(u(x))$ is constant for any solution $u(x)$. But at ξ, $u(x)$ has higher energy than $v(x)$, and at η the order is reversed, a contradiction. □

The following result from P. Korman [21] gives a detailed description of the solution shape for large λ. (In [21] we proved this result for balls in $\mathbb{R}^n$.) If for some reason solutions cannot be of that shape, it follows that there are no positive solutions of (2.1) for large λ. Recall that root α of $f(u)$ is called *stable* if $f(\alpha)=0$ and $f'(\alpha)<0$.

THEOREM 2.1. *Let* $u(x,\lambda)$ *be a positive solution of* (2.1), *that exists for all* $\lambda>\bar{\lambda}$, *for some* $\bar{\lambda}>0$. *Assume that either* $\lim_{u\to\infty}\frac{f(u)}{u}=\infty$, *or there is* $u_0>0$, *so that* $f(u)\leqslant 0$ *for* $u\geqslant u_0$. *Then the interval* $(-1,1)$ *can be decomposed into a union of open intervals, whose total length* $=2$, *so that on each such subinterval* $u(x,\lambda)$ *tends to a stable root of* $f(u)$, *as* $\lambda\to\infty$.

EXAMPLE. Assume that $f(u)<0$ for $0<u<\bar{u}$, with some $\bar{u}>0$, $f(u)>0$ for $u>\bar{u}$, and $\lim_{u\to\infty}\frac{f(u)}{u}=\infty$, e.g., $f(u)=u^p-1$, with $p>1$. Then the problem

$$u''+\lambda\big(u^p-1\big)=0,\quad -1<x<1,\qquad u(-1)=u(1)=0$$

has no positive solution for λ large enough. Indeed, since $f(u)$ has no stable roots, solution cannot exhibit the behaviour described in the above theorem, and hence the solution cannot exist for all large λ.

The bifurcation approach applies also to the quasilinear problems of the type

$$\big(\varphi(u')\big)'+\lambda f(u)=0\quad\text{for } -1<x<1,\qquad u(-1)=u(1)=0. \tag{2.7}$$

The prominent example is that of p-Laplacian $\varphi(t)=t|t|^{p-2}$, with $p\geqslant 2$. Motivated by this example, we assume that $\varphi(t)\in C^2(\mathbb{R}\setminus\{0\})$ satisfies

$$\varphi'(t)>0\quad\text{for all } t\neq 0. \tag{2.8}$$

We consider weak solutions of (2.7), which are of class $C[-1,1]\cap C^1(-1,1)\cap C^2((-1,1)\setminus\{0\})$. (Since the problem is degenerate elliptic, the value of $u''(0)$ might be infinite.)

Assuming condition (2.8), we will show that the conclusions of Lemmas 2.1, 2.2, 2.4 and 2.5 hold verbatim for problem (2.7). In case $\varphi(t) = t|t|^{p-2}$, Lemmas 2.3 and 2.8 hold too. The proofs are basically the same, but there are some difficulties due to degeneracy. For example, in the proof of Lemma 2.1 it is not apparent that $u(x)$ is symmetric with respect to ξ in case $\xi = 0$. (If $\xi \neq 0$, the proof is as before.) We therefore combine the first two lemmas to assert that the solution has the same shape as before.

LEMMA 2.10. *Assuming condition* (2.8), *any positive solution of* (2.7) *is an even function*, *with* $u'(x) > 0$ *on* $(-1, 0)$, *and* $u'(x) < 0$ *on* $(0, 1)$.

PROOF. We need to adjust the definition of energy. Define $\Phi(z) = \int_0^z t\varphi'(t)\,\mathrm{d}t$. Then the energy $\Phi(u'(x)) + \lambda F(u(x))$ is constant (in case of p-Laplacian, $\frac{p}{p-1}|u'(x)|^p + \lambda F(u(x)) = constant$). Using the energy, we conclude as before that $u(x)$ cannot have any points of minimum inside the interval $(-1, 1)$. Also, since the energy is constant, it follows that

$$u'(-1) = -u'(1). \tag{2.9}$$

To prove the symmetry, we consider $v(x) \equiv u(-x)$. The function $v(x)$ satisfies the same problem (2.7). By (2.9) it has the same initial conditions at $x = 1$ as $u(x)$. Hence $u(x) \equiv v(x)$. And finally, observe that an even function with no interior minimums has the desired shape. □

It is easy to see that Lemma 2.3 holds in case of p-Laplacian. Since we need homogeneity for rescaling, we cannot assert it for the general problem (2.7). Next we consider the linearized problem for (2.7)

$$\begin{aligned} &\big(\varphi'(u')w'\big)' + \lambda f'(u)w = 0 \quad \text{for } -1 < x < 1, \\ &w(-1) = w(1) = 0. \end{aligned} \tag{2.10}$$

LEMMA 2.11. *Assume that condition* (2.3) *holds. If problem* (2.10) *admits a nontrivial solution*, *then it does not change sign*, *i.e. we may assume that* $w(x) > 0$ *on* $(-1, 1)$. *Moreover*, *in the case of p-Laplacian*, *the following generalization of the formula* (2.5) *holds*:

$$\int_{-1}^{1} f(u)w\,\mathrm{d}x = \frac{2}{p\lambda}\varphi'\big(u'(1)\big)u'(1)w'(1). \tag{2.11}$$

PROOF. The proof of the first statement is exactly the same as before. Turning to the other one, we differentiate Eq. (2.10)

$$\big(\varphi'(u')u_x'\big)' + \lambda f'(u)u_x = 0. \tag{2.12}$$

Combining problems (2.10) and (2.12), we have

$$\varphi'\big(u'(x)\big)\big(u''(x)w(x) - u'(x)w'(x)\big) = -\varphi'\big(u'(1)\big)u'(1)w'(1). \tag{2.13}$$

We now integrate over $(-1,1)$. In the case of p-Laplacian, $\varphi(t)=t|t|^{p-2}$, $\varphi'(t)=(p-1)|t|^{p-2}$, and $t\varphi'(t)=(p-1)\varphi(t)$. Hence the second term on the left is equal to $-(p-1)\int_{-1}^{1}\varphi(u'(x))w'(x)\,\mathrm{d}x$. Integrating this term by parts, we can combine it with the first term of the resulting equation. Finally, we observe that $\varphi'(u'(x))u''(x)=-\lambda f(u(x))$. □

2.2. *Convex nonlinearities*

For convex nonlinearities one can give an exhaustive description of the bifurcation diagrams for problem (2.1), since we are able to show that the solution curve cannot turn more than once. Namely, we assume that $f(u)\in C^2(\overline{\mathbb{R}}_+)$ satisfies

$$f(0)>0,\quad \text{and}\quad f(u)>0\quad \text{for } u>0, \tag{2.14}$$

$$f''(u)>0\quad \text{for } u>0, \tag{2.15}$$

$$f(u)\geqslant au-b\quad \text{for } u>0 \text{ and some constants } a>0 \text{ and } b\geqslant 0. \tag{2.16}$$

THEOREM 2.2. *Problem* (2.1), *under the above conditions*, *has at most two positive solutions for any* λ. *Moreover, all positive solutions lie on a unique curve in the* $(\lambda,u(0))$ *plane. This curve begins at the point* $(\lambda=0,u(0)=0)$, *and either it tends to infinity at some* $\lambda_0>0$, *or else it bends back at some* $\lambda_0>0$, *and then continues without any more turns*, *and tends to infinity at some* $\bar{\lambda}$, $0\leqslant\bar{\lambda}<\lambda_0$.

PROOF. When $\lambda=0$ we have a trivial solution $u=0$. It follows by the implicit function theorem that for small $\lambda>0$ there is a continuous in λ curve of solutions, passing through $(0,0)$. We claim that this solution curve cannot be continued indefinitely for all $\lambda>0$. Assume on the contrary that solutions can be continued as $\lambda\to\infty$. Write problem (2.1) in the corresponding integral form,

$$u(x)=\lambda\int_{-1}^{1}G(x,\xi)f\bigl(u(\xi)\bigr)\,\mathrm{d}\xi, \tag{2.17}$$

where $G(x,\xi)$ is the corresponding Green's function. It is well known that $G(x,\xi)>0$ for all $0<x,\xi<1$. Since by our assumptions $f(u)$ is bounded from below by a positive constant, it follows that $u(x)$ will become uniformly large, as $\lambda\to\infty$. Let $\phi_1(x)$ be the principal eigenvalue of $-u''$ on the interval $(-1,1)$ subject to zero boundary conditions, and λ_1 the corresponding principal eigenvalue (here $\phi_1(x)=\cos\frac{\pi}{2}x$, and $\lambda_1=\frac{\pi^2}{4}$). Multiplying Eq. (2.1) by $\phi_1(x)$ and integrating, we have

$$\begin{aligned}\lambda_1\int_{-1}^{1}u\phi_1\,\mathrm{d}x&=-\int_{-1}^{1}u''\phi_1\,\mathrm{d}x=\lambda\int_{-1}^{1}f(u)\phi_1\,\mathrm{d}x\\&\geqslant\lambda a\int_{-1}^{1}u\phi_1\,\mathrm{d}x-\lambda b\int_{-1}^{1}\phi_1\,\mathrm{d}x.\end{aligned}$$

But this leads to a contradiction, as $\lambda \to \infty$, since $\int_{-1}^{1} u\phi_1 \, \mathrm{d}x \to \infty$. ($u(x)$ is a convex function, tending to infinity.)

Let λ_0 denote the supremum of λ, for which the solution curve continues to the right. It is possible that solutions become unbounded as $\lambda \to \lambda_0$ (this is one of the possibilities discussed in the statement of the theorem). So assume that the solutions stay bounded, as $\lambda \to \lambda_0$. Passing to the limit in the integral form of the equation, see (2.17), we conclude the existence of a bounded solution $u_0(x)$, which our solution curve enters at $\lambda = \lambda_0$. Clearly the pair $(\lambda_0, u_0(x))$ is a singular solution of (2.1) (since it cannot be continued to the right in λ). We show next that the Crandall–Rabinowitz Theorem 1.2 applies at $(\lambda_0, u_0(x))$.

We begin by recasting the equation in operator form $F(\lambda, u) = 0$, where the map $F(\lambda, u) : \mathbb{R}_+ \times C^2(-1, 1) \to C(-1, 1)$ is defined by $F(\lambda, u) = u''(x) + \lambda f(u(x))$. Observe that $F_u(\lambda, u)w$ is given by the left-hand side of the linearized equation (2.2). Since the point (λ_0, u_0) is singular, it follows that the linearized equation (2.2) has a nontrivial solution $w(x)$, which is positive by Lemma 2.4. By Lemma 2.5 it follows that the null-space $N(F_u(\lambda_0, u_0)) = \mathit{span}\{w(x)\}$ is one-dimensional, and then $\mathit{codim} R(F_u(\lambda_0, u_0)) = 1$, since $F_u(\lambda_0, u_0)$ is a Fredholm operator of index zero. To apply the Crandall–Rabinowitz Theorem 1.2, it remains to show that $F_\lambda(\lambda_0, u_0) \notin R(F_u(\lambda_0, u_0))$. Assuming the contrary would imply existence of a nontrivial $v(x)$, a solution of

$$v'' + \lambda_0 f_u(\lambda_0, u_0)v = f(\lambda_0, u_0) \quad \text{for } x \in (-1, 1), \qquad v(-1) = v(1) = 0.$$

By the Fredholm alternative (or just multiplying this equation by w, Eq. (2.2) by v, subtracting and integrating)

$$\int_{-1}^{1} f(\lambda_0, u_0) w(x) \, \mathrm{d}x = 0,$$

which contradicts Lemma 2.8. (Since $f(0) > 0$, we have $u'(1) < 0$, and also $w'(1) < 0$ by uniqueness of initial value problems. Hence by Lemma 2.8, the above integral is positive.) Hence the Crandall–Rabinowitz Theorem 1.2 applies at $(\lambda_0, u_0(x))$.

Next we compute the direction of bifurcation at the point $(\lambda_0, u_0(x))$. According to the Crandall–Rabinowitz Theorem 1.2, the solution set near the point $(\lambda_0, u_0(x))$ is a curve $\lambda = \lambda(s)$, $u = u(s)$, with $\lambda(0) = \lambda_0$ and $u(0) = u_0(x)$. Observe that $\lambda'(0) = 0$, and $u_s(0) = w(x)$, according to the Crandall–Rabinowitz theorem. If we can show that $\lambda''(0) < 0$, it would follow that the solution curve turns to the left at $(\lambda_0, u_0(x))$, since the function $\lambda(s)$ has a maximum at $s = 0$. To express $\lambda''(s)$, we differentiate Eq. (2.1) twice in s, obtaining

$$u_{ss}'' + \lambda f_u u_{ss} + \lambda f_{uu} u_s^2 + 2\lambda' f_u u_s + \lambda'' f = 0, \qquad u_{ss}(-1) = u_{ss}(1) = 0.$$

Letting $s = 0$, we have by the above remarks

$$u_{ss}'' + \lambda_0 f_u u_{ss} + \lambda_0 f_{uu} w^2 + \lambda''(0) f = 0, \qquad u_{ss}(-1) = u_{ss}(1) = 0. \tag{2.18}$$

Multiplying this equation by w, Eq. (2.2) by u_{ss}, subtracting and integrating

$$\lambda''(0) = -\lambda_0 \frac{\int_{-1}^{1} f_{uu}(\lambda_0, u_0(x)) w^3(x)\, \mathrm{d}x}{\int_{-1}^{1} f(\lambda_0, u_0) w(x)\, \mathrm{d}x} < 0, \tag{2.19}$$

with the last inequality due to convexity of $f(u)$ and Lemma 2.8.

The above analysis is valid not only at the point $(\lambda_0, u_0(x))$, but also at any other critical point. Hence, locally near any critical point, the solution set consists of a parabola-like curve, facing to the left in the $(\lambda, u(0))$ plane. Hence, after bending back at the point $(\lambda_0, u_0(x))$, our solution curve continues for decreasing λ, without ever encountering critical points. (At any critical point, we could not possibly have a parabola-like curve, described above, since our curve has arrived from the right.) Hence, the solution curve continues globally, without any turns, and it has to go to infinity at some $\bar{\lambda} \geqslant 0$. We then have one of the solution curves, described in the theorem, and the maximum value of solutions on this curve, $u(0)$ varies from zero to infinity. Hence all possible maximum values are "taken", and so by Lemma 2.3 this curve exhausts the solution set. □

REMARKS.

1. If, moreover, we have

$$\lim_{u \to \infty} \frac{f(u)}{u} = \infty, \tag{2.20}$$

   then the curve cannot go to infinity at a finite λ. Hence, it will bend back at some λ_0, and go to infinity at $\lambda = 0$. Indeed, since $f(u) > 0$, the solutions $u(x, \lambda)$ are concave in x. So that if $u(x, \lambda)$ gets large near some $\lambda = \lambda_1$, it would have to get uniformly large on some interval, say on $(-1/2, 1/2)$. Writing our equation in the form $u'' + \lambda \frac{f(u)}{u} u = 0$, and using the Sturm comparison theorem, we conclude that the positive solution $u(x)$ has to vanish on $(-1/2, 1/2)$, which is impossible.
2. One can show that the solutions on the lower branch are increasing in λ, for all $x \in (-1, 1)$, see P. Korman and T. Ouyang, [34,35]. (On the upper branch this is no longer true, but the maximal value $u(0)$ is increasing as we trace the branch, i.e. it is decreasing in λ.)
3. Our assumptions did not require for $f(u)$ to be increasing.
4. All three possibilities, mentioned in the theorem, can actually occur, see Fig. 1 for the results of numerical computations. Observe that in the second and third cases $f(u)$ is asymptotically linear, and bifurcation from infinity happens.

2.3. *S-shaped solution curves*

We saw in the previous section that solution curves are relatively simple for convex $f(u)$. If $f(u)$ changes concavity, then the solution curve may admit more than one turn. One

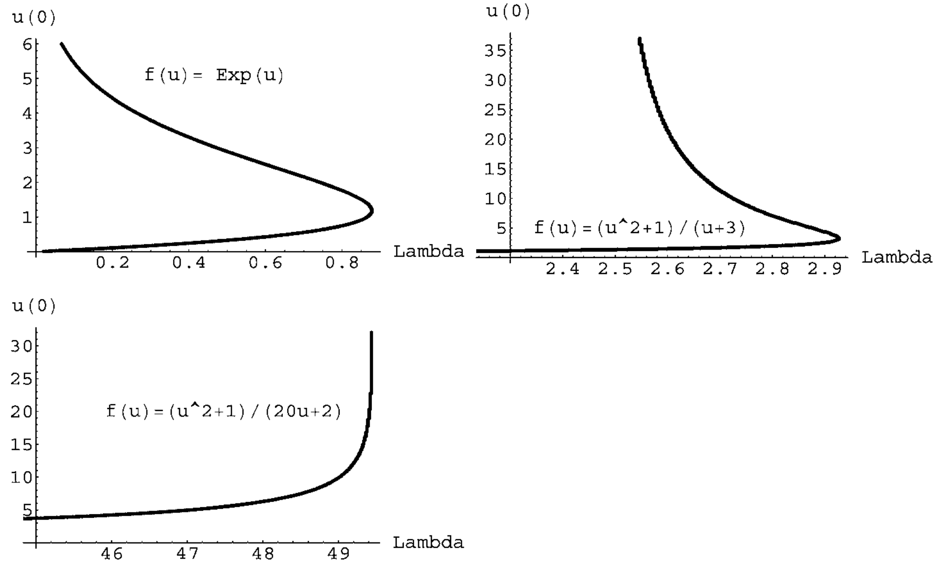

Fig. 1. Three types of solution curves for convex $f(u)$.

prominent nonlinearity, with change in concavity, is connected to combustion theory, see the nice book of J. Bebernes and D. Eberly [7]. Namely, we consider the problem

$$u'' + \lambda e^{\frac{au}{u+a}} = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{2.21}$$

where a is a constant (this problem is referred to as "the perturbed Gelfand problem" in [7]). In case $a \leqslant 4$, the problem is easy. In that case $uf'(u) - f(u) < 0$ for all $u > 0$, and hence all positive solutions are nonsingular. This means that the solution curve is monotone, i.e. it continues for all $\lambda > 0$ without any turns. S.-H. Wang [59] has proved existence of a constant a_0, so that for $a > a_0$ the solution curve of (2.21) is exactly S-shaped, i.e. it starts at $\lambda = 0$, $u = 0$, it makes exactly two turns, and then it continues for all $\lambda > 0$ without any more turns. S.-H. Wang [59] gave an approximation of the constant $a_0 \simeq 4.4967$. That paper, as well as all previous ones, used a time map approach. P. Korman and Y. Li [28] have applied the bifurcation approach to the problem to show the exactness of the S-shaped curves, and they also improved the value of the constant to $a_0 \simeq 4.35$, i.e. for $a > a_0$ the solution sets are S-shaped curves. S.-H. Wang [59] has conjectured existence of critical number $\bar{a}$, so that for $a \leqslant \bar{a}$ the solution curve is monotone, while for $a > \bar{a}$ the solution curve is exactly S-shaped. Recently, P. Korman, Y. Li and T. Ouyang [33] has given a computer assisted proof of the S.-H. Wang's conjecture. Numerical calculations show that $\bar{a} \simeq 4.07$.

We are going to discuss the S-shaped curves, mostly following P. Korman and Y. Li [29]. However, in that paper time maps were still used at one point. Subsequently, in P. Korman and J. Shi [40] an argument not using time maps was given. Next we present this result, dealing with instability of solutions (it also turned out to be of independent interest), after we recall the notion of stability. For any solution $u(x)$ of (2.1) let $(\mu, w(x))$ denote the principal eigenpair of the corresponding linearized equation, i.e. $w(x) > 0$ satisfies

$$w'' + \lambda f'(u)w + \mu w = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0. \tag{2.22}$$

The solution $u(x)$ of (2.1) is called unstable if $\mu < 0$, otherwise it is stable.

Let $F(u) = \int_0^u f(t)\,\mathrm{d}t$, $h(u) = 2F(u) - uf(u)$. The instability result from P. Korman and J. Shi [40] is

THEOREM 2.3. *Assume that* $f \in C^1[0, \infty)$, $f(0) > 0$, *and for some* $\alpha > \beta > 0$ *we have*:

$$h'(u) \geqslant 0 \quad \textit{for } 0 < u < \beta, \qquad h'(u) \leqslant 0 \quad \textit{for } \beta < u < \alpha, \tag{2.23}$$

$$h(\alpha) \leqslant 0. \tag{2.24}$$

Then the solution of (2.1) *with* $u(0) = \alpha$ *is unstable*, *if it exists*.

PROOF. We have $h(0) = 0$, $h'(u) = f(u) - uf'(u)$, $h'(0) = f(0) > 0$. It follows from our conditions that $h(u)$ is unimodular on $[0, \alpha]$, and it takes its positive maximum at $u = \beta$. Define $x_0 \in (0, 1)$ by $u(x_0) = \beta$. We then conclude

$$\begin{aligned} &f\big(u(x)\big) - u(x) f'\big(u(x)\big) \leqslant 0 \quad \text{on } (0, x_0), \\ &f\big(u(x)\big) - u(x) f'\big(u(x)\big) \geqslant 0 \quad \text{on } (x_0, 1). \end{aligned} \tag{2.25}$$

We also remark that by the condition (2.24),

$$\int_0^1 \big[f(u) - uf'(u)\big]u'(x)\,\mathrm{d}x = \int_0^1 \frac{\mathrm{d}}{\mathrm{d}x} h\big(u(x)\big)\,\mathrm{d}x = -h(\alpha) \geqslant 0. \tag{2.26}$$

Assume now that $u(x)$ is stable, i.e. $\mu \geqslant 0$ in (2.22). Without loss of generality, we assume that $w > 0$ in $(-1, 1)$. By the maximum principle, $u'(1) < 0$, so near $x = 1$ we have $-u'(x) > w(x)$. Since $-u'(0) = 0$, while $w(0) > 0$, the functions $w(x)$ and $-u'(x)$ change their order at least once on $(0, 1)$. We claim that the functions $w(x)$ and $-u'(x)$ change their order exactly once on $(0, 1)$. (We ignore the points where these functions merely “touch”.) Observe that $-u'(x)$ satisfies

$$(-u')'' + \lambda f'(u)(-u') = 0 \quad \text{on } (0, 1), \tag{2.27}$$

while $w(x)$ (and any of its positive multiples) is a supersolution of the same equation. Let $x_3 \in (0, 1)$ be the largest point where $w(x)$ and $-u'(x)$ change the order. Assuming the claim to be false, let x_2, with $0 < x_2 < x_3$, be the next point where the order changes. We have $w > -u'$ on (x_2, x_3), and the opposite inequality to the left of x_2. Since $w(0) > -u'(0)$, there is another point $x_1 < x_2$, where the order is changed. We can now find a constant $\gamma > 1$, and a point $x_0 \in (x_1, x_2)$ so that a $\gamma w(x)$, a supersolution of (2.27), touches at x_0 from above a solution $-u'(x)$ of the same equation, a contradiction.

Since the point of changing of order is unique, by scaling of $w(x)$ we can achieve

$$\begin{aligned} -u'(x) &\leqslant w(x) \quad \text{on } (0, x_0), \\ -u'(x) &\geqslant w(x) \quad \text{on } (x_0, 1). \end{aligned} \tag{2.28}$$

Using (2.25), (2.28), and also (2.26), we have

$$\int_0^1 \bigl[f(u) - uf'(u)\bigr] w(x)\,\mathrm{d}x < \int_0^1 \bigl[f(u) - uf'(u)\bigr]\bigl(-u'(x)\bigr)\,\mathrm{d}x \leqslant 0, \tag{2.29}$$

since the integrand on the left is pointwise smaller than the one on the right. On the other hand, multiplying Eq. (2.22) by u, Eq. (2.1) by w, subtracting and integrating over (0, 1), we have

$$\int_0^1 \bigl[f(u) - uf'(u)\bigr] w(x)\,\mathrm{d}x = \frac{\mu}{\lambda}\int_0^1 uw\,\mathrm{d}x \geqslant 0,$$

which contradicts (2.29). So $\mu < 0$. □

We will consider a class of nonlinearities, including $f(u) = \mathrm{e}^{\frac{au}{u+a}}$, so let us list our assumptions. We assume that $f(u) \in C^2[0, \bar{u}]$ for some $0 < \bar{u} \leqslant \infty$, and that it satisfies

$$f(u) > 0 \quad \text{for all } 0 \leqslant u < \bar{u}. \tag{2.30}$$

We assume $f(u)$ to be convex-concave, i.e. there an $\alpha \in (0, \bar{u})$, such that

$$f''(u) > 0 \quad \text{for } u \in (0, \alpha), \qquad f''(u) < 0 \quad \text{for } u \in (\alpha, \bar{u}). \tag{2.31}$$

We define a function $I(u) = f^2(u) - 2F(u)f'(u)$, where as before $F(u) = \int_0^u f(t)\,\mathrm{d}t$. Assume there is a $\beta > \alpha$, such that

$$I(\beta) = f^2(\beta) - 2F(\beta)f'(\beta) \geqslant 0. \tag{2.32}$$

The following lemma has originated from P. Korman, Y. Li and T. Ouyang [30].

LEMMA 2.12. *Assume that $f(u)$ satisfies conditions* (2.30)–(2.32). *Let (λ, u) be any critical point of* (2.1), *such that $u(0) \geqslant \beta$, and let $w(x)$ be the corresponding solution of the linearized problem* (2.2). *Then*

$$\int_0^1 f''\bigl(u(x)\bigr)u_x(x)w^2(x)\,\mathrm{d}x > 0. \tag{2.33}$$

PROOF. We shall derive a convenient expression for the integral in (2.33). Differentiate (2.2)

$$w_x'' + \lambda f'(u)w_x + \lambda f''(u)u_x w = 0. \tag{2.34}$$

Multiplying Eq. (2.34) by w, Eq. (2.2) by w_x, integrating and subtracting, we express

$$\lambda \int_0^1 f''(u) u_x w^2 \, \mathrm{d}x = w'^2(1) - \lambda w^2(0) f'\bigl(u(0)\bigr). \tag{2.35}$$

By differentiation, we verify that $u''(x)w(x) - u'(x)w'(x)$ is constant for all x, and hence

$$u''(x)w(x) - u'(x)w'(x) = -\lambda w(0) f\bigl(u(0)\bigr) \quad \text{for all } x \in [-1, 1]. \tag{2.36}$$

Evaluating this expression at $x = 1$, we obtain

$$w'(1) = \frac{\lambda w(0) f(u(0))}{u'(1)}. \tag{2.37}$$

Multiplying (2.1) by u', and integrating over $(0, 1)$, we have

$$u'^2(1) = 2\lambda F\bigl(u(0)\bigr). \tag{2.38}$$

Using (2.38) and (2.37) in (2.35), we finally express

$$\lambda \int_0^1 f''(u) u_x w^2 \, \mathrm{d}x = \frac{w^2(0)}{2F(\rho)} I(\rho), \tag{2.39}$$

where we denote $\rho = u(0)$. By our assumption, $I(\beta) \geqslant 0$. Since

$$I'(\rho) = -2F(\rho) f''(\rho) > 0 \quad \text{for } \rho \geqslant \beta,$$

we conclude that $I(\rho) > I(\beta) \geqslant 0$, and the lemma follows. ☐

The following lemma contains the crucial trick, which has originated from P. Korman, Y. Li and T. Ouyang [30]. It says that for convex-concave problems only turns to the right are possible in the (λ, α) plane, once the maximum value of the solution, $u(0)$, has reached a certain level.

LEMMA 2.13. *In the conditions of the preceding Lemma* 2.12, *assume again that* $u(0) \geqslant \beta$, *and* $w(x)$ *the corresponding solution of the linearized problem* (2.2). *Then*

$$\int_0^1 f''\bigl(u(x)\bigr) w^3(x) \, \mathrm{d}x < 0. \tag{2.40}$$

PROOF. Let $(\lambda, u(x))$ be a critical point of (2.1). Since $u(0) \geqslant \beta > \alpha$, it follows that the function $f''(u(x))$ changes sign exactly once on $(0, 1)$, say at x_0. Then we have

$$f''\bigl(u(x)\bigr) < 0 \quad \text{for } x \in (0, x_0), \qquad f''\bigl(u(x)\bigr) > 0 \quad \text{for } x \in (x_0, 1). \tag{2.41}$$

We have proved in Theorem 2.3 that the functions $w(x)$ and $-u'(x)$ intersect exactly once on $(0,1)$. By scaling $w(x)$ we may assume that they intersect at x_0. ($w(x)$ is a solution of a linear problem, and hence it is defined up to a constant multiple.) In view of Lemma 2.12, we then have

$$\int_0^1 f''\big(u(x)\big)w^3(x)\,\mathrm{d}x < \int_0^1 f''\big(u(x)\big)w^2(-u_x)\,\mathrm{d}x < 0,$$

since by (2.41) the integrand on the right is pointwise greater than the one the left. □

The same approach can be used to prove the following more general theorem, which was implicit in P. Korman, Y. Li and T. Ouyang [30], see also T. Ouyang and J. Shi [50].

THEOREM 2.4 [30].
(i) *Assume that* $f(0) \geqslant 0$, $f''(u) < 0$ *for* $0 < u < u_0$, $f''(u) > 0$ *for* $u > u_0$. *Then only turns to the left are possible on the solution curve.*

(ii) *Assume that* $f(0) \leqslant 0$, $f''(u) > 0$ *for* $0 < u < u_0$, $f''(u) < 0$ *for* $u > u_0$. *Then only turns to the right are possible on the solution curve.*

(Of course, in both cases we conclude existence of at most two positive solutions, with the maximum values lying in the first positive hump of $f(u)$.)

We are now ready for the main result of this section, see P. Korman and Y. Li [29].

THEOREM 2.5. *Assume that* $f(u)$ *satisfies conditions* (2.30) *and* (2.31), *and moreover,*

$$\lim_{u\to\infty} \frac{f(u)}{u} = 0. \tag{2.42}$$

With $h(u) \equiv 2F(u) - uf(u)$, *assume that*

$$h(\alpha) < 0. \tag{2.43}$$

Then the solution set of (2.1) *consists of one curve, which is exactly S-shaped, i.e. it starts at* $\lambda = 0$, $u = 0$, *it makes exactly two turns, and then it continues for all* $\lambda < \infty$, *without any more turns.*

PROOF. By the implicit function theorem there is a curve of positive solutions of (2.1), starting at $\lambda = 0$, $u = 0$. As in Theorem 2.2, this curve continues for increasing λ, until a possible singular solution (λ_0, u_0) is reached, at which point the Crandall–Rabinowitz Theorem 1.2 applies. By (2.19) it follows that only turns to the left are possible if $u(0) < \alpha$, since $f(u)$ is convex for $u \in (0,\alpha)$. Until the first critical point (λ_0, u_0) is reached, the solutions are stable. Indeed, the solution curve starts at $(\lambda = 0, u = 0)$, which is a stable solution (the principal eigenvalue of the corresponding linearized problem $= \frac{\pi^2}{2}$), while any change of stability requires a passage through a singular point. By Theorem 2.3 when

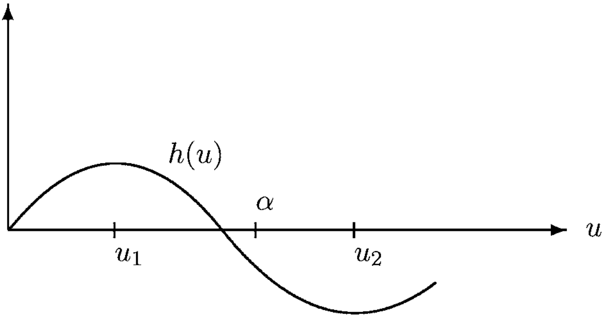

Fig. 2. The function $h(u)$.

$u(0) = \alpha$ the solution is unstable. Hence a singular solution was reached before that, and since only turns to the left are possible when $u(x) < \alpha$, it follows that *exactly one* turn has occurred, and at $u(0) = \alpha$ the solution curve travels to the left.

We now show that the solution curve keeps traveling to the left, until $u(0)$ increases to the level when only turns to the right are possible. For that we take a close look at the function $h(u) = 2F(u) - uf(u)$. Since

$$h'(u) = f(u) - uf'(u), \qquad h''(u) = -uf''(u),$$

it follows that the function $h'(u)$ is decreasing on $(0, \alpha)$ and increasing on (α, ∞). We have $h'(0) = f(0) > 0$, and so $h'(u)$ can have at most two roots. We claim that it has exactly two roots, u_1 and u_2 with $h'(u)$ being positive on $(0, u_1) \cup (u_2, \infty)$, and negative on (u_1, u_2). Indeed, existence of the first root is clear, since $h(0) = 0$ and $h(\alpha) < 0$. As for the second root u_2, if it did not exist, we would have

$$uf'(u) > f(u) \quad \text{for all } u > \alpha. \tag{2.44}$$

Integrating (2.44),

$$f(u) > \frac{f(\alpha)}{\alpha} u \quad \text{for all } u > \alpha,$$

contradicting the assumption (2.42). So that the function $h(u)$ starts with $h(0) = 0$, it is increasing on $(0, u_1)$, decreasing on (u_1, u_2), with absolute minimum at u_2, and then it increases on the interval (u_2, ∞) (see Fig. 2). By Theorem 2.3 the solution curve keeps traveling to the left, while $u(0) \in (\alpha, u_2)$.

We claim that for $u(0) > u_2$ Lemma 2.13 applies. For that we need to check that for $\beta = u_2$ the condition (2.32) holds. Indeed, since $h(u_2) < 0$, we have $f(u_2)u_2 > 2F(u_2)$. Hence

$$I(u_2) = f^2(u_2) - 2F(u_2)f'(u_2) > f^2(u_2) - u_2 f(u_2) f'(u_2) = 0,$$

and the claim follows (observe that $f'(u_2) = \frac{f(u_2)}{u_2} > 0$). By Lemma 2.13, only turns to the right are possible when $u(0) > u_2$.

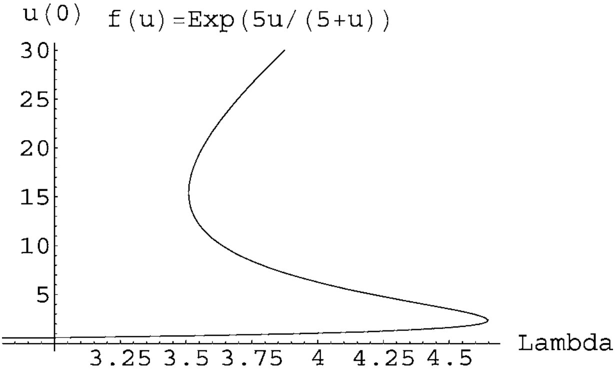

Fig. 3. An S-shaped solution curve.

Let us now put it all together. We have a curve of solutions, which starts at $(\lambda = 0, u = 0)$. As we travel on this curve, $u(0)$ is always increasing. By the time we reach $u(0) = \alpha$ level, the solution curve has made exactly one turn to the left. When $\alpha < u(0) < u_2$ the solution curve travels to the left. When $u(0) > u_2$, the solution curve cannot travel to the left indefinitely, since it is easy to see that solutions are bounded for bounded λ. Hence, the curve must turn to the right. Since for $u(0) > u_2$ only turns to the right are possible, exactly one such turn occurs. It follows that the solution curve is exactly S-shaped. $\square$

In Fig. 3 we give an example of an S-shaped solution curve. Notice that *Mathematica* has drawn the vertical axis around $\lambda = 3$. Also observe that an actual S-shaped solution curve is way different from what most people would draw by hand.

2.4. *Cubic-like nonlinearities*

We again consider the problem

$$u'' + \lambda f(u) = 0, \quad x \in (-1, 1), \qquad u(-1) = u(1) = 0, \tag{2.45}$$

where $f(u)$ behaves like a cubic with three distinct roots, with a model example $f(u) = (u - a)(u - b)(c - u)$. Namely, we assume that the function $f(u) \in C^2(\overline{\mathbb{R}}_+)$ has three nonnegative roots at $0 \leqslant a < b < c$, and

$$\begin{gathered} f(u) > 0 \quad \text{on } [0, a) \cup (b, c), \qquad f(u) < 0 \quad \text{on } (a, b) \cup (c, \infty), \\ \int_a^c f(u)\,\mathrm{d}u > 0. \end{gathered} \tag{2.46}$$

Moreover, we assume there is an $\alpha > b$, so that

$$f''(u) > 0 \quad \text{for } 0 \leqslant u < \alpha, \qquad f''(u) < 0 \quad \text{for } u > \alpha. \tag{2.47}$$

This problem was originally studied using time-maps, see J. Smoller and A. Wasserman [57] and S.-H. Wang [59,60]. In P. Korman, Y. Li and T. Ouyang [30] the bifurcation approach was applied. The case of $a = 0$ turned out to be easier for both time-maps and bifurcation approaches, while in case $a > 0$ some restriction on a (a bound from above) was necessary for both approaches.

We shall do the case $a = 0$ first, after two simple lemmas. (I.e. $f(u)$ is modeled on $f(u) = u(u-b)(c-u)$.) Let $\beta \in (b, c)$ be the unique point satisfying

$$f'(\beta) = \frac{f(\beta)}{\beta}. \tag{2.48}$$

(I.e. the point where the straight line through the origin is tangent to the graph of $y = f(u)$.) Clearly, $\beta > \alpha$. The following lemma shows that no turns of the solution curve are possible until the maximum value of the solution reaches a certain level.

LEMMA 2.14. *Assume that $f(u) \in C^2$ satisfies conditions* (2.46) *and* (2.47). *If $u(x)$ is a critical solution of* (2.45) *then*

$$u(0) > \beta. \tag{2.49}$$

PROOF. We claim that

$$f'(u) > \frac{f(u)}{u} \quad \text{for } 0 < u < \beta. \tag{2.50}$$

Indeed, denote $p(u) = uf'(u) - f(u)$. Then $p(0) = p(\beta) = 0$, and $p'(u) = uf''(u)$, which implies that $p(u)$ is increasing on $(0, \alpha)$ and decreasing on (α, β). Then (2.50) follows, and hence by Lemma 2.6 the linearized equation has only the trivial solution, in case $u(0) \leqslant \beta$. □

LEMMA 2.15. *Assume that $f(u) \in C^2$ satisfies conditions* (2.46) *and* (2.47), *with $a = 0$. Assume $u(x)$ is a critical solution of* (2.45), *and let $w(x)$ be solution of the corresponding linearized problem* (2.2). *Then*

$$\int_0^1 f''(u) w^3 \, \mathrm{d}x < 0. \tag{2.51}$$

PROOF. We begin by showing that

$$\int_0^1 f''(u) u_x^2 w \, \mathrm{d}x = 0. \tag{2.52}$$

We have (using Eqs. (2.45) and (2.2))

$$(u''w' - u'w'')' = \lambda f''(u) u_x^2 w.$$

Integrating over $(0,1)$, and using that $w''(1) = -\lambda f'(u(1))w(1) = 0$ and $u''(1) = -\lambda f(u(1)) = -\lambda f(0) = 0$, we conclude (2.52) (it is here that we use that $f(0) = 0$, i.e. $a = 0$).

We now proceed similarly to Lemma 2.13. Similarly to that lemma, we show that the functions $w(x)$ and $-u'(x)$ intersect exactly once on $(0,1)$. Observe that by Lemma 2.14, we have $u(0) > \beta > \alpha$ at any critical solution $u(x)$. Let $\xi \in (0,1)$ be the point where $u(\xi) = \alpha$. By scaling $w(x)$ we may assume that $w(x)$ and $-u'(x)$ intersect at ξ. Then on the interval $(0,\xi)$, where $f''(u(x))$ is negative, we have $u_x^2 < w^2$, while on the interval $(\xi,1)$, where $f''(u(x))$ is positive, we have $u_x^2 > w^2$. We then have, in view of (2.52),

$$\int_0^1 f''(u)w^3\,\mathrm{d}x < \int_0^1 f''(u)u_x^2 w\,\mathrm{d}x = 0,$$

since the integral on the left is pointwise smaller than the one on the right. □

The following theorem is from P. Korman, Y. Li and T. Ouyang [30].

THEOREM 2.6. *Assume that* $f(u) \in C^2$ *satisfies conditions* (2.46) *and* (2.47), *with* $a = 0$. *Then there is a critical* λ_0 *such that for* $\lambda < \lambda_0$ *problem* (2.45) *has no positive solutions, it has exactly one positive solution at* $\lambda = \lambda_0$, *and exactly two positive solutions for* $\lambda > \lambda_0$. *Moreover, all solutions lie on a single solution curve, which for* $\lambda > \lambda_0$ *has two branches* $0 < u^-(x,\lambda) < u^+(x,\lambda)$, *with* $u^+(x,\lambda)$ *strictly monotone increasing in* λ, *and* $\lim_{\lambda\to\infty} u^+(x,\lambda) = c$. *On the lower branch,* $u^-(0,\lambda)$ *is monotone decreasing,* $\lim_{\lambda\to\infty} u^-(x,\lambda) = 0$ *for all* $x \neq 0$, *while* $u^-(0,\lambda) > b$ *for all* λ. *We also have* $\lim_{\lambda\to\infty} u^-(0,\lambda) = \theta$, *where* θ *is defined by the relation* $\int_0^\theta f(u)\,\mathrm{d}u = 0$.

PROOF. If $\lambda c > \frac{\pi^2}{4}$, then existence of positive solutions follows by monotone iterations. Indeed, $\phi = c$ is a supersolution of (2.45), while $\psi = \epsilon \cos\frac{\pi}{2}x$ is a subsolution of the same problem, if ϵ is chosen sufficiently small ($\lambda = \frac{\pi^2}{4}$ and $\phi_1 = \cos\frac{\pi}{2}x$ give, of course, the principal eigenpair of the Laplacian on $(-1,1)$). We now continue the positive solution (any one) for decreasing λ. At regular points we use the implicit function theorem for continuation, while the singular point(s) will be discussed below. We cannot continue this curve indefinitely for decreasing λ, since it has no place to go. Indeed, solutions are bounded by c, and so the right hand side of Eq. (2.45) goes to zero, and hence $u(x) \to 0$ as $\lambda \to 0$. But that is impossible, since $f(u)$ is negative near $u = 0$, while at the point of maximum $u''(0) \leqslant 0$. Hence at some critical $\lambda = \lambda_0$ and $u = u_0$ the solution curve cannot be continued further for decreasing λ.

As before, we show that the Crandall–Rabinowitz Theorem 1.2 applies at (λ_0, u_0). According to Lemma 2.15 a turn to the right must occur at this, and any other critical point. Hence, exactly one turn happens, and the solution curve has exactly two branches.

The properties of the solution branches are easy to prove, see [30]. □

In Fig. 4 we give an example for the above theorem. Notice that *Mathematica* has chosen the point $(6,2)$ as the point where the axes intersect.

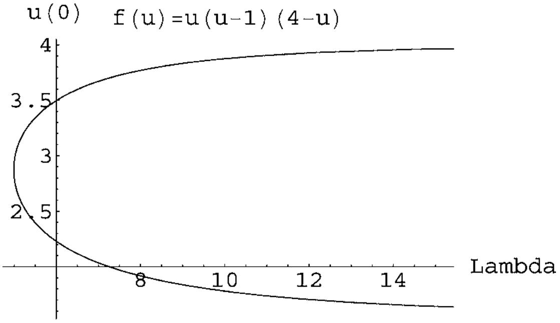

Fig. 4. A parabola-like solution curve, when $a = 0$.

Next we turn to the case when $a > 0$. I.e. we assume that $f(u)$ satisfies conditions (2.46) and (2.47), with the cubic $f(u) = (u - a)(u - b)(c - u)$ being our model example. Similarly to the above, we denote by $\beta \in (b, c)$ the unique point satisfying

$$f'(\beta) = \frac{f(\beta)}{\beta - a}. \tag{2.53}$$

(I.e. the point where the straight line through the point $(a, 0)$ is tangent to the graph of $y = f(u)$.) Clearly, $\beta > \alpha$. The proof of the following lemma is similar to that of Lemma 2.14, and so we omit it (see [33]).

LEMMA 2.16. *Assume that* $f(u) \in C^2$ *satisfies conditions* (2.46) *and* (2.47). *If* $u(x)$ *is a critical solution of* (2.45) *then*

$$u(0) > \beta. \tag{2.54}$$

We define a constant $\tau \in (b, c)$ by $f'(\tau) = 0$, i.e. τ is the second root of $f'(u)$. We also recall the function $I(u) = f^2(u) - 2F(u)f'(u)$, defined previously.

LEMMA 2.17. *Assume that* $f(u) \in C^2$ *satisfies conditions* (2.46) *and* (2.47). *Assume that either*

$$\int_a^\tau f(u)\,\mathrm{d}u \leqslant 0, \tag{2.55}$$

or

$$I(\beta) \geqslant 0. \tag{2.56}$$

If $u(x))$ *is a critical solution of* (2.45), *and* $w(x)$ *is a solution of the corresponding linearized problem*, *then*

$$\int_0^1 f''\bigl(u(x)\bigr)u'(x)w^2(x)\,\mathrm{d}x > 0. \tag{2.57}$$

PROOF. For any solution of (2.45) we have $\int_a^{u(0)} f(u)\,\mathrm{d}u > 0$ (just multiply the equation by u' and integrate between $x = 0$ and the point $x = \xi$, such that $u(\xi) = a$). So that if (2.55) holds, then $u(0) > \tau$, i.e. $f'(u(0)) < 0$. Then (2.57) follows from formula (2.35) for the integral (2.57). In case condition (2.56) holds, the proof proceeds the same way as in Lemma 2.12. □

REMARK. We can replace condition (2.55) by requiring that $u(0) > \tau$.

The following result was essentially proved in P. Korman, Y. Li and T. Ouyang [33].

THEOREM 2.7. *Assume that* $f(u) \in C^2$ *satisfies conditions* (2.46) *and* (2.47). *Assume either the condition* (2.56) *is satisfied, or else assume that any solution of problem* (2.45), *with* $u(0) \in (\beta, \tau)$ *is noncritical. Then there exists a critical* λ_0, *such that problem* (2.45) *has exactly one positive solution for* $0 < \lambda < \lambda_0$, *exactly two positive solutions at* $\lambda = \lambda_0$, *and exactly three positive solutions for* $\lambda_0 < \lambda < \infty$. *Moreover, all solutions lie on two smooth solution curves. One of the curves, referred to as the lower curve, starts at* ($\lambda = 0, u = 0$), *it is increasing in* λ, *and* $\lim_{\lambda\to\infty} u(x,\lambda) = a$ *for* $x \in (-1, 1)$. *The upper curve is a parabola-like curve with exactly one turn to the right.*

PROOF. The properties of the lower curve are easy to prove. According to the implicit function theorem there is a curve of positive solutions, starting at $\lambda = 0$ and $u = 0$. Since $f'(u) < 0$ when $u < a$, it follows by Lemma 2.7 that solutions are nondegenerate, and hence they can be continued for all $\lambda > 0$. It is easy to see that the solutions on this curve are increasing in λ, and $\lim_{\lambda\to\infty} u(x,\lambda) = a$ for all $x \in (-1, 1)$, see [30].

Turning to the upper curve, recall that critical solutions are possible only if $u(0) > \beta$. If condition (2.56) holds then we have (2.57). The same way as in Lemma 2.12 we show that at any critical point

$$\int_0^1 f''\bigl(u(x)\bigr) w^3(x)\,\mathrm{d}x < 0, \tag{2.58}$$

which means that only turns to the right are possible on the upper curve. Similarly to Theorem 2.6 for the $a = 0$ case, we show existence of solutions on the upper curve, and that the upper curve has to turn. Hence, exactly one turn occurs on the upper curve, and its other properties are proved similarly to the $a = 0$ case. In the other case, when (2.55) holds, we know that no critical points are possible, until $u(0) > \tau$. But then again (2.57) holds, which implies (2.58), and we proceed the same way as in the first case. □

The above result shows that either one gets "lucky" at the level $u(0) = \beta$, i.e. condition (2.56) holds, and the above Theorem 2.7 applies, or else the interval (β, τ) is "dangerous", i.e. we need to rule out the possibility of any turns when $\beta < u(0) < \tau$ (since we cannot tell their direction). For that computer assisted proofs are feasible. In fact, in a recent paper P. Korman, Y. Li and T. Ouyang [33] have given three independent computer assisted proofs in case of a cubic. We describe their result next. Let $f(u) = (u - a)(u - b)(c - u)$,

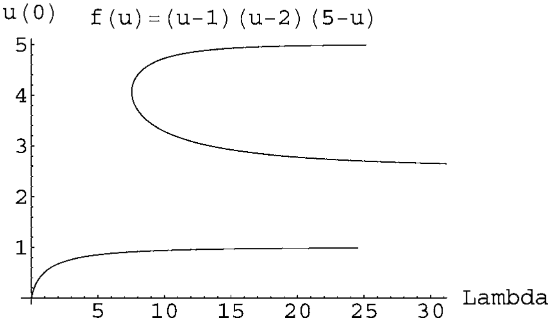

Fig. 5. A two-piece solution curve for a cubic, with $a > 0$.

with $0 < a < b < c$. For problem (2.45) to have a positive solution it is necessary that $\int_a^c f(u)\,\mathrm{d}u > 0$, i.e.

$$b < \frac{a+c}{2}. \tag{2.59}$$

It was shown in [33] that under the necessary condition (2.59) the above Theorem 2.7 applies, providing an exact multiplicity result for the general cubic. In the next section we present a new tool, used in [33] to give one of the computer assisted proofs.

2.5. *Computing the location of bifurcation*

Assume that for the problem

$$u''(x) + f\bigl(u(x)\bigr) = 0, \quad x \in (-1,1), \qquad u(-1) = u(1) = 0 \tag{2.60}$$

bifurcation occurs at $u(0) = \alpha$, i.e. the corresponding linearized problem

$$w''(x) + f'\bigl(u(x)\bigr)w(x) = 0, \quad x \in (-1,1), \qquad w(-1) = w(1) = 0 \tag{2.61}$$

admits a nontrivial solution. The following result of P. Korman, Y. Li and T. Ouyang [33] provides a way to determine all possible α's at which bifurcation may occur, i.e. the corresponding solution of (2.60) is singular.

THEOREM 2.8. *A positive solution of problem* (2.60) *with the maximal value* $\alpha = u(0)$ *is singular if and only if*

$$G(\alpha) \equiv F(\alpha)^{1/2} \int_0^\alpha \frac{f(\alpha) - f(\tau)}{[F(\alpha) - F(\tau)]^{3/2}}\,\mathrm{d}\tau - 2 = 0. \tag{2.62}$$

PROOF. We need to show that the problem (2.61) has a nontrivial solution. By direct verification the function $w(x) = -u'(x)\int_x^1 \frac{1}{u'^2(t)}\,\mathrm{d}t$ satisfies Eq. (2.61). Also $w(1) = 0$. If we also have

$$w'(0) = 0, \tag{2.63}$$

then since $u(x)$ is an even function, the function $w(x)$ is also even (by uniqueness for initial value problems), and hence $w(-1) = 0$, which gives us a nontrivial solution of (2.61). Conversely, every nontrivial solution of (2.61) is an even function, and hence (2.63) is satisfied.

Using Eq. (2.60), we compute

$$w'(x) = f\bigl(u(x)\bigr)\int_x^1 \frac{1}{u'^2(t)}\,\mathrm{d}t + \frac{1}{u'(x)}.$$

Since the energy $\frac{u'^2}{2}(x) + F(u(x))$ is constant,

$$\frac{u'^2}{2}(x) + F\bigl(u(x)\bigr) = F\bigl(u(0)\bigr) = F(\alpha).$$

On the interval (0, 1) we express

$$u'(x) = -\sqrt{2}\sqrt{F(\alpha) - F(u(x))}. \tag{2.64}$$

We use this formula in the integral $\int_x^1 \frac{1}{u'(t)^2}\,\mathrm{d}t$, and then we make a change of variables $t \to s$, by letting $s = u(t)$. We have

$$\begin{aligned} 2^{3/2}\int_x^1 \frac{1}{u'^2(t)}\,\mathrm{d}t &= -\int_x^1 \frac{u'(t)\,\mathrm{d}t}{[F(\alpha) - F(u(t))]^{3/2}} \\ &= -\int_{u(x)}^0 \frac{1}{[F(\alpha) - F(s)]^{3/2}}\,\mathrm{d}s. \end{aligned} \tag{2.65}$$

Using formulas (2.64) and (2.65), we express

$$2^{3/2}w'(x) = \int_0^{u(x)} \frac{f(u(x))}{[F(\alpha) - F(\tau)]^{3/2}}\,\mathrm{d}\tau - \frac{2}{[F(\alpha) - F(u(x))]^{1/2}}. \tag{2.66}$$

If we try to set here $x = 0$, then both terms on the right are infinite. Instead, we observe that

$$\begin{aligned} -\frac{2}{[F(\alpha) - F(u)]^{1/2}} &= -\int_0^u \frac{\mathrm{d}}{\mathrm{d}\tau}\frac{2}{[F(\alpha) - F(\tau)]^{1/2}}\,\mathrm{d}\tau - \frac{2}{F(\alpha)^{1/2}} \\ &= -\int_0^u \frac{f(\tau)}{[F(\alpha) - F(\tau)]^{3/2}}\,\mathrm{d}\tau - \frac{2}{F(\alpha)^{1/2}}. \end{aligned} \tag{2.67}$$

Using (2.67) in (2.66), we obtain

$$2^{3/2}w'(x) = \int_0^{u(x)} \frac{f(u(x)) - f(\tau)}{[F(\alpha) - F(\tau)]^{3/2}}\,\mathrm{d}\tau - \frac{2}{F(\alpha)^{1/2}}. \tag{2.68}$$

The integral on the right is now nonsingular, as we let $x \to 0$. At $x = 0$ we see that (2.63) is equivalent to (2.62). □

In case of a cubic $f(u) = (u - a)(u - b)(c - u)$, P. Korman, Y. Li and T. Ouyang [33] have used formula (2.62) to give a computer assisted proof that there are no turning points in the dangerous region, $u(0) \in (\beta, \tau)$, thus establishing the exact multiplicity result (Theorem 2.7) from the previous section.

2.6. *Computing the direction of bifurcation*

We have seen that at a critical solution $u(x)$ of (2.60) the integral $I = \int_0^1 f''(u)w^3\,\mathrm{d}x$ governs the direction of bifurcation. Also, it is known that in case $I \neq 0$ a critical solution $u(x)$ is *nondegenerate*, i.e. it persists when the equation is perturbed slightly (i.e. the turning points persist under perturbations), see, e.g., [32]. The following result from P. Korman, Y. Li and T. Ouyang [33] allows one to compute the integral I as a function of $\alpha = u(0)$.

THEOREM 2.9. *At any critical solution $u(x)$ of* (2.60), *with* $u(0) = \alpha$,

$$I = c\int_0^\alpha f''(u)\left(\int_u^\alpha f(s)\,\mathrm{d}s\right)\left(\int_0^u \frac{\mathrm{d}s}{(\int_s^\alpha f(t)\,\mathrm{d}t)^{3/2}}\right)^3 \mathrm{d}u, \tag{2.69}$$

where $c = \frac{1}{4\sqrt{2}}u'^3(1)w'^3(1) > 0$.

This formula is rather involved, but using *Mathematica* it can be evaluated numerically. In a future paper, with Y. Li and T. Ouyang, we use this result to handle equations modeled on polynomials of arbitrary power.

2.7. *Pitchfork bifurcation and symmetry breaking*

So far for the problem

$$u'' + \lambda f(u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0 \tag{2.70}$$

we have considered the cases when $f(0) \geqslant 0$. As we have observed earlier, this condition implies that $|u_x(\pm 1, \lambda)| \neq 0$ for any positive solution $u(x, \lambda)$. Since we also know that

$u_x(x, \lambda) < 0$ for all $x \in (0, 1)$, there is no way for a positive solution to become sign-changing, as we vary λ (no interior roots, or zero slope at the boundary are possible). The situation changes drastically in case

$$f(0) < 0. \tag{2.71}$$

A solution may develop a zero slope at the boundary, and become sign-changing. In fact, a pitchfork bifurcation usually happens. In addition to the sign-changing symmetric solution, two symmetry-breaking solution emerge, see P. Korman [20].

Let us consider the problem

$$u''(x) + u^{2k}(x) - \lambda = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{2.72}$$

which we will relate to the problems of type (2.70) shortly. Here $k \geqslant 1$ is an integer. For $k = 1$ this problem was exhaustively analyzed in J.C. Scovel's Ph.D. thesis [54], and in H.P. McKean and J.C. Scovel [44]. They used explicit integration via elliptic functions, which means that their method does not work for $k > 1$. It turned out that the solution set of (2.72) for $k = 1$ consists of infinitely many identically looking curves. Each curve is a parabola like curve, with pitchfork bifurcation on one of the branches. (I.e. there is exactly one turn, and exactly one point of pitchfork bifurcation on each curve, see Fig. 6.) V. Anuradha and R. Shivaji [6] have studied a related problem. Using the quadrature technique, they showed existence of infinitely many points of bifurcation. In [20] P. Korman had used bifurcation theory to approach problem (2.72), and in particular the case of $f(u) = u^{2k}$, with $k > 1$. We were able to generalize some, but not all, of the results of H.P. McKean and J.C. Scovel [44].

It is well known that at $\lambda = 0$ there exists a unique positive solution of (2.72). This solution is known to be nondegenerate, so that we can continue it for small $\lambda > 0$. Setting $u(x) = \mu v(x)$, with μ determined by the relation $\mu^{2k} = \lambda$, we convert problem (2.72) into (a particular case of the problem (2.70))

$$\begin{aligned} &v''(x) + \lambda\big(v^{2k}(x) - 1\big) = 0, \quad \text{for } -1 < x < 1, \\ &v(-1) = v(1) = 0, \end{aligned} \tag{2.73}$$

where λ is a new parameter (equal to μ^{2k-1}). With the parameter now in front of the nonlinearity, Lemma 2.8 applies, and hence we can always continue both positive and sign-changing solutions of (2.73) (and also of (2.72). Observe that the curve of positive solutions does not turn for $\lambda > 0$ (for $g(v) \equiv v^{2k} - 1$, we have $vg'(v) > g(v)$ for all $v > 0$). By Theorem 2.1 this curve of positive solutions cannot be continued for all $\lambda > 0$ (the function $g(v) = v^{2k} - 1$ has no "stable" roots, i.e. roots where derivative is negative). By the Sturm's comparison theorem, it is easy to see that positive solutions cannot become unbounded at a finite λ. Hence, solutions on this curve must eventually stop being positive, and the only way this can happen is that $u'(\pm 1) = 0$ at some λ_0 (in view of the symmetry of positive solutions).

We now outline the pitchfork bifurcation analysis for the general problem (2.70), and more details can be found in P. Korman [20]. So suppose problem (2.70) has a curve of positive solutions $u(x,\lambda)$, so that for $\lambda < \lambda_0$ we have $u_x(1,\lambda) < 0$, while at $\lambda = \lambda_0$ we have $u_x(1,\lambda_0) = 0$. The function $u_x(x,\lambda_0)$ is then a solution of the corresponding linearized problem ($u_0 = u(x,\lambda_0)$)

$$w'' + \lambda_0 f'(u_0)w = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0. \tag{2.74}$$

The null-space of the linearized problem is one-dimensional (by Lemma 2.5), and it is spanned by the odd function $u_x(x,\lambda_0)$. If we now restrict to the space of even functions, the null-space will be empty, and hence by the implicit function theorem the solution curve $u(x,\lambda)$ continues for $\lambda > \lambda_0$, as sign-changing symmetric (even) solutions. We can compute the tangential direction for this curve at $\lambda = \lambda_0$:

$$u_\lambda(x,\lambda_0) = xu_x(x,\lambda_0). \tag{2.75}$$

Indeed, the function $u_\lambda(x,\lambda_0) - xu_x(x,\lambda_0)$ is an even function, solving the linearized problem (2.74). Hence it must be zero, justifying (2.75). If we let $v = u - u(x,\lambda)$, where $u(x,\lambda)$ is the curve of sign-changing symmetric solutions, then for $\lambda > \lambda_0$ we have a trivial solution $v = 0$. We showed in [20] that the conditions of the Crandall–Rabinowitz theorem on bifurcation from the trivial solutions are satisfied at $\lambda = \lambda_0$, giving rise to a parabola-like curve of symmetry breaking solutions (see also M. Ramaswamy [51], which we used in [20]). Their tangential direction is given by $u_x(x,\lambda_0)$.

One of the reasons we were not able to fully recover the beautiful results of McKean and Scovel [44], is that we could not tell the direction of the pitchfork bifurcation: which way the symmetry breaking solutions bifurcate, toward $\lambda > \lambda_0$ or $\lambda < \lambda_0$? Recently X. Hou, P. Korman and Y. Li [17] has given a computer assisted way (again computer assisted!) to settle this question. Here is their result, which says that the pitchfork opens forward.

THEOREM 2.10. *Consider problem* (2.72), *with* $1 \leqslant k \leqslant 720$. *Let* λ_0 *be the point of pitchfork bifurcation.* (*The value of* λ_0 *was explicitly computed in* [17].) *Then there is a negative* $\bar{\lambda} = \bar{\lambda}(k) < 0$, *so that problem* (2.72) *has exactly two positive solutions for* $\bar{\lambda} < \lambda < 0$, *it has exactly one positive and one negative solution on* $(0,\lambda_0)$. *Moreover, there is a* $\lambda_1(k) > \lambda_0$, *so that problem* (2.72) *has four solutions on* (λ_0,λ_1), *one negative* (*and symmetric*), *one sign-changing and symmetric* (*with* $u(0) > 0$), *and two asymmetric solutions.*

In Fig. 6 we present a picture of pitchfork bifurcation from [17] (produced by X. Hou). We draw $u'(-1)$ as a function of λ. In that figure solid lines denote positive and negative solutions, the dashed line denotes sign-changing symmetric solutions, and the doted lines stand for the symmetry breaking solutions.

2.8. *Sign-changing solutions*

We consider sign-changing solutions of the two point problem

$$u'' + f(u) = 0 \quad \text{for } x \in (0,1), \qquad u(0) = u(1) = 0. \tag{2.76}$$

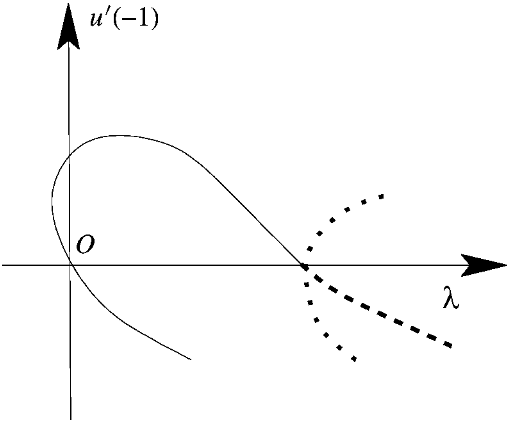

Fig. 6. Pitchfork bifurcation.

Notice that we pose the problem over the interval (0, 1), since sign-changing solutions need not be symmetric. Also we do not have λ in front of $f(u)$ (one can think that λ is absorbed into $f(u)$). Corresponding linearized problem is

$$w'' + f'(u)w = 0 \quad \text{for } x \in (0,1), \qquad w(0) = w(1) = 0. \tag{2.77}$$

The following result is from P. Korman and T. Ouyang [39].

THEOREM 2.11. *Let $f \in C^2(\mathbb{R})$, and assume that either one of the following two inequalities holds*:

$$\frac{f(u)}{u} - f'(u) > 0\ (< 0) \quad \textit{for almost every } u \in \mathbb{R}. \tag{2.78}$$

Then any solution of problem (2.76), *satisfying $u'(0) \neq 0$, is nonsingular* (*i.e.* (2.77) *admits only the trivial solution*).

PROOF. Assume on the contrary that problem (2.77) admits a nontrivial solution $w(x)$.

Step 1. We show that the number of roots of u and w inside (0, 1) differs by one. Assume for definiteness that $f'(u) > \frac{f(u)}{u}$ for almost every $u \in \mathbb{R}$. If we regard (2.76) as a linear equation $u'' + \frac{f(u)}{u}u = 0$, then by the Sturm comparison theorem the function $w(x)$ has a root between any two roots of $u(x)$. Since both functions vanish at the endpoints, $x = 0$ and $x = 1$, it follows that w has one more interior root than u.

Step 2. We will show that u and w have the same number of interior roots. This will result in a contradiction, proving the theorem. We denote by n_u the number of interior roots of u, and use the same notation for other functions. The functions w and u' satisfy the same linear equation, and hence their roots are interlaced. Since w vanishes at the endpoints and u' does not, it follows that $n_{u'} = n_w + 1$. Since $n_{u'} = n_u + 1$, it follows that $n_u = n_w$. □

Corresponding to the solution $u(x)$ of (2.76) we may consider an eigenvalue problem

$$\varphi'' + f'(u)\varphi + \mu\varphi = 0 \quad \text{for } x \in (0,1), \qquad \varphi(0) = \varphi(1) = 0. \tag{2.79}$$

The eigenvalues of (2.79) form a sequence $\mu_1 < \mu_2 < \cdots < \mu_n < \cdots$, tending to infinity. The number of negative eigenvalues is called the *Morse index* of $u(x)$. The following theorem is from P. Korman and T. Ouyang [39].

THEOREM 2.12. *Let $u(x)$ any solution of problem* (2.76), *with k interior roots and satisfying $u'(0) \neq 0$. Then the Morse index of $u(x)$ is either k or $k+1$. Moreover, the Morse index equals k if the first inequality in* (2.78) *holds, and it equals $k+1$ if the second inequality in* (2.78) *holds.*

Similar results for balls in $\mathbb{R}^n$ have been given in J. Shi and J. Wang [56].

2.9. *The Neumann problem*

Consider the Neumann problem

$$u'' + \lambda f(u) = 0 \quad \text{for } 0 < x < 1, \qquad u'(0) = u'(1) = 0. \tag{2.80}$$

We are interested in the solution branches bifurcating off constant solutions. By translation we may assume the constant solution to be zero, i.e. we assume that

$$f(0) = 0, \tag{2.81}$$

and that $f(u) \in C^2(a^-, a^+)$ for some $-\infty \leqslant a^- < 0 < a^+ \leqslant \infty$. We assume that

$$uf(u) > 0 \quad \text{on } \bigl(a^-, a^+\bigr). \tag{2.82}$$

We consider solutions of (2.80) such that $u(x) \in (a^-, a^+)$. It suffices to consider only the *increasing* solutions of (2.80), i.e. $u'(x) > 0$ on $(0,1)$, since other solutions can be produced from them by reflection, pasting and scaling. Clearly we have $u(0) < 0 < u(1)$, since $x = 0$ and $x = 1$ are points of minimum and maximum, respectively.

The corresponding linearized problem is

$$w'' + \lambda f'(u)w = 0 \quad \text{for } 0 < x < 1, \qquad w'(0) = w'(1) = 0. \tag{2.83}$$

If this problem has only the trivial solution, then the solution branches bifurcating from zero do not turn. A simple condition for this to happen goes back to Z. Opial [47], see also R. Schaaf [53]. Namely, we assume that either one of the following two inequalities holds:

$$\frac{f(u)}{u} - f'(u) > 0\ (< 0) \quad \text{for every } u \in \bigl(a^-, a^+\bigr) \setminus \{0\}. \tag{2.84}$$

It is an elementary exercise to show that (2.84) will follow if either one of the following two inequalities holds:

$$uf''(u) > 0\ (< 0) \quad \text{for every } u \in \left(a^-, a^+\right) \setminus \{0\}. \tag{2.85}$$

The following result is of course known, see [47] and [53], although previously it was stated in different terms (involving monotonicity of time maps), and proved by different methods.

THEOREM 2.13. *Assume that conditions* (2.81), (2.82) *and* (2.84) (*or* (2.85)) *hold, and* $u(x) \in (a^-, a^+)$ *for all* $x \in (0, 1)$. *Then the linearized problem* (2.83) *admits only the trivial solution.*

PROOF. Assume on the contrary that $w(x)$ is a nontrivial solution of (2.83). Observe that $u'(x)$ satisfies the same equation (2.83), $u'(x) > 0$ for $x \in (0, 1)$ and $u'(0) = u'(1) = 0$. It follows by the Sturm comparison theorem that $w(x)$ has exactly one root on (0, 1); we call it η, i.e. $w(\eta) = 0$. We may assume (by scaling) that $w(0) < 0$ and $w(1) > 0$, and hence $w'(\eta) > 0$. Let ξ denote the unique root of the increasing solution $u(x)$, i.e. $u(\xi) = 0$ and $u'(\xi) > 0$. Writing Eq. (2.80) in the form $u'' + \lambda\frac{f(u)}{u}u = 0$, and combining it with (2.83), we have

$$(u'w - uw')' + \lambda\left[\frac{f(u)}{u} - f'(u)\right]uw = 0. \tag{2.86}$$

We now consider two cases.

Case 1. $\xi \leqslant \eta$. Assume that the first inequality holds in (2.84), i.e. the quantity in the square bracket in (2.86) is positive. We integrate (2.86) over the interval $(\eta, 1)$, where both $u(x)$ and $w(x)$ are positive

$$u(\eta)w'(\eta) + \lambda\int_\eta^1\left[\frac{f(u)}{u} - f'(u)\right]uw\,\mathrm{d}x = 0.$$

We have a contradiction, since both terms on the left are positive.

If the second inequality holds in (2.84), i.e. the quantity in the square bracket in (2.86) is negative, we integrate (2.86) over the interval $(0, \xi)$, where both $u(x)$ and $w(x)$ are negative

$$u(\xi)w'(\xi) + \lambda\int_0^\xi\left[\frac{f(u)}{u} - f'(u)\right]uw\,\mathrm{d}x = 0.$$

Again, we have a contradiction, since both terms on the left are negative.

Case 2. $\xi \geqslant \eta$. If the first inequality holds in (2.84), we integrate over $(0, \eta)$, where both $u(x)$ and $w(x)$ are negative

$$-u(\eta)w'(\eta) + \lambda \int_0^\eta \left[\frac{f(u)}{u} - f'(u)\right] uw \, \mathrm{d}x = 0.$$

Both terms on the left are positive, a contradiction. If the second inequality holds in (2.84), we integrate over $(\xi, 1)$, where both $u(x)$ and $w(x)$ are positive

$$-u'(\xi)w(\xi) + \lambda \int_\xi^1 \left[\frac{f(u)}{u} - f'(u)\right] uw \, \mathrm{d}x = 0.$$

Both terms on the left are negative, again we have a contradiction. □

Beyond this simple theorem, we know of only two results on the Neumann problem. The first one is due to R. Schaaf [53]. It dealt with monotonicity of time maps, here we rephrase it in terms of nondegeneracy of solutions.

THEOREM 2.14 [53]. *Assume that the function $f(u)$ is either an $A - B$ or C function on the interval (a^-, a^+). Then the linearized problem* (2.83) *admits only the trivial solution.*

The other one is from P. Korman [23].

THEOREM 2.15. *Assume that $f(u)$ satisfies $f'(u) > 0$ and $f'''(u) < 0$ on the interval $(0, a^+)$, and $f''(u) > 0$ on (a^-, a^+). Then the linearized problem* (2.83) *admits only the trivial solution.*

The last result is not very satisfactory. Its only advantage is that no third order assumptions on $f(u)$ are made on $(a^-, 0)$, while on $(0, a^+)$ such functions are of class $A - B$. R. Schaaf's result is better.

According to the condition (2.85), we can handle the cases when $f(u)$ changes concavity at its root $u = 0$. But what if it keeps the same concavity? We wish to pose the following problem.

PROBLEM. Assume that $f(0) = 0$, and

$$f''(u) > 0 \quad \text{for } u \in \left(a^-, a^+\right).$$

Is it true that any increasing solution of the Neumann problem (2.80), with values in (a^-, a^+), is nondegenerate (i.e. (2.83) has only the trivial solution)?

Using bifurcation approach, we can also treat some nonautonomous problems. For example,

$$u'' + \lambda b(x) f(u) = 0 \quad \text{for } 0 < x < 1, \qquad u'(0) = u'(1) = 0, \tag{2.87}$$

with the given function $b(x)$ being positive and continuous. The corresponding linearized problem is now

$$w'' + \lambda b(x) f'(u) w = 0 \quad \text{for } 0 < x < 1, \qquad w'(0) = w'(1) = 0. \tag{2.88}$$

Formula (2.86) still holds here (with an extra factor of $b(x)$ in front of the square bracket), and hence the arguments of the above theorem can be used unchanged. In particular, we conclude as above that any nontrivial solution of (2.88) cannot vanish exactly once. Unlike the autonomous problem, we cannot yet conclude that $w(x)$ is zero, since we cannot automatically exclude the possibilities that $w(x)$ has no roots, or at least two roots. We need to introduce another condition:

$$f'(u) \geqslant 0 \quad \text{for every } u \in \left(a^-, a^+\right). \tag{2.89}$$

THEOREM 2.16. *Assume that* $b(x)$ *is positive and continuous on* $[0, 1]$, *and* $f(u) \in C^1[a^-, a^+]$ *satisfies conditions* (2.81), (2.82), (2.89), *and the first inequality holds in* (2.84). *Let* $u(x)$ *be an increasing solution of the Neumann problem* (2.80), *satisfying* $u(x) \in (a^-, a^+)$ *for all* $x \in (0, 1)$. *Then the linearized problem* (2.88) *admits only the trivial solution.*

PROOF. As we mentioned above, the arguments used in proof of Theorem 2.13 apply here as well. In case the first inequality holds in (2.84), we have proved in Theorem 2.13 that $w(x)$ cannot vanish on either side of ξ, the root of $u(x)$. Hence $w(x)$ keeps the same sign over $(0, 1)$. But then integrating the linearized equation (2.88),

$$\int_0^1 b(x) f'(u) w \, \mathrm{d}x = 0,$$

which is a contradiction, since the integrand is of one sign. □

As an example, the function $f(u) = u - u^3$ satisfies the conditions of this theorem on the interval $(-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}})$.

2.10. *Similarity of the solution branches*

We saw in the previous two sections that under the same condition (2.84) we could prove nondegeneracy for both sign-changing solutions, and for the Neumann problem. It turns out that a curve of solutions with an odd number of sign changes is always similar to curves of solutions of Neumann problems. (I.e. both curves have the same number of critical points, with the same direction of turns.) Let us fix the notation, before we state the result. We consider the problem

$$u'' + \lambda f(u) = 0 \quad \text{on } (0, 1), \tag{2.90}$$

subject to either Dirichlet

$$u(0) = u(1) = 0, \tag{2.91}$$

or Neumann

$$u'(0) = u'(1) = 0 \tag{2.92}$$

boundary conditions. We shall consider the solutions as the positive parameter λ varies, and refer to the solution curves as either Dirichlet or Neumann branches, depending on the boundary conditions used. Recall that by Lemma 2.1 any solution of Eq. (2.90) is symmetric with respect to any of its critical points. This implies, in particular, that either minimum or maximum occurs at any critical point. It follows that any solution of Neumann problem is determined by its values on any subinterval $I \subset (0, 1)$, whose end-points are two consecutive critical points of $u(x)$. We can then obtain the solution on the entire interval $(0, 1)$ through reflections and translations. We refer to I, and any other interval uniquely determining the solution through reflections and translations, as a *determining interval*. The interval I, joining two consecutive critical points of $u(x)$, is also a determining interval for the Dirichlet problem. Another determining interval for Dirichlet problem is (ξ, η), where $0 \leqslant \xi < \theta < \eta \leqslant 1$ are three consecutive roots of $u(x)$. This interval contains both positive and negative humps (and all positive (negative) humps are translations of one another).

As we vary λ the number of roots on Dirichlet branches, as well as the number of monotonicity changes on Neumann branches, remain constant. Indeed, by Lemma 2.2 solutions of (2.90) cannot have points of positive maximum and negative minimum, and there is no other mechanism by which extra roots (or monotonicity changes) may be created.

The natural way to distinguish the Dirichlet branches is by the number of interior roots, and the Neumann branches can be identified by the number of changes of monotonicity (both properties remain constant on the solution curves). Any solution of the Dirichlet problem with at least one interior root contains a solution of the Neumann problem on a subinterval of $(0, 1)$. Indeed, just consider the solution between two consecutive critical points. In order for solutions of the Neumann problem to contain in turn a solution of the Dirichlet problem, we need to impose some conditions on $f(u)$. Namely, we assume that

$$f(0) = 0, \tag{2.93}$$

and there exist two constants $-\infty \leqslant m < 0 < M \leqslant \infty$ so that

(f1) $f(u) > 0$ for $u \in (0, M)$,
(f2) $f(u) < 0$ for $u \in (m, 0)$.

LEMMA 2.18. *Under conditions* (2.93), (f1) *and* (f2) *any solution of the Neumann problem for* (2.90), *satisfying*

$$m < u(x) < M \quad \textit{for all } x \tag{2.94}$$

has a root between any two critical points.

PROOF. Follows immediately, by multiplying the equation (2.90) by u', and integrating between any two consecutive critical points. □

DEFINITION. We call two solution branches of (2.90) to be *similar* if for any solution on the either branch there is a determining interval so that by stretching of x, or by reflection $x \to 2a - x$, for some $a \in (0, 1)$, we obtain a solution from the other branch on a (different) determining interval. Clearly, if solution branches are similar then the corresponding solution curves in (λ, u) "plane" have the same shape.

The following result was proved in this form by P. Korman [24], although it can also be found in R. Schaaf [51].

THEOREM 2.17. *All Neumann branches of* (2.90) *are similar, and if* $f(u)$ *satisfies conditions* (2.93), (f1) *and* (f2), *while all solutions satisfy* (2.94), *then the Neumann branches are similar to the Dirichlet ones with an odd number of interior roots* (*and these Dirichlet branches are also all similar*).

PROOF. We begin with Neumann branches. If a Neumann solution changes monotonicity twice, then its increasing part is a reflection of its decreasing part with respect to $x = \frac{1}{2}$. If a Neumann solution changes monotonicity n times, then all critical points occur at i/n, $i = 1, \dots, n-1$, and the graphs of solution on all intervals where it is increasing (decreasing) are translations of one another. Since an interval connecting any two critical points is a determining interval, the equivalence of the Neumann branches follows (via rescaling). □

If a Dirichlet solution has $2k-1$ interior roots, it has k identical positive humps and k identical negative humps. Assume for definiteness that solution starts with a negative hump, followed by a positive one, and so on. If ξ is the first point of (negative) minimum of $u(x)$, then the first interior root occurs at 2ξ. If $2\xi + \eta$ is the point of the first (positive) maximum, then the second interior root occurs at $2\xi + 2\eta$. The last critical point, a positive maximum, occurs at $1 - \eta$. Observe that $k(2\xi + 2\eta) = 1$, i.e. $\xi + \eta = \frac{1}{2k}$. So while both ξ and η vary with λ, $u(x)$ solves the Neumann problem on the interval $(\xi, 1 - \eta)$, and this interval has a *fixed* length of

$$1 - \eta - \xi = \frac{2k-1}{2k}.$$

So that any Dirichlet solution curve "carries" inside it a solution of a Neumann problem on a fixed interval (which can be made to be (0, 1) by rescaling), and hence the Dirichlet branch cannot have any more complexity (like extra turns) than any Neumann branch.

Conversely, consider the Neumann problem with $2k+1$ changes of monotonicity. Assume for definiteness that $u(0) < 0$. Then $u(1) > 0$. Assume that $\xi = \xi(\lambda)$ is the smallest interior root, and $1 - \eta$ is the largest one, $\eta = \eta(\lambda)$. On the interval $(0, 1)$ we then have $2k+1$ negative half-humps, each of width ξ, and $2k+1$ positive ones, each of width η. So that $\xi + \eta = \frac{1}{2k+1}$. On the interval $(\xi, 1 - \eta)$ we have a solution of the Dirichlet problem with $2k-1$ interior roots, and the length of this interval is

$$1 - \eta - \xi = \frac{2k}{2k+1},$$

which does not vary with λ. So that any Neumann branch "carries" inside it a solution of a Dirichlet problem on a fixed interval, and hence the Neumann branch cannot have any more complexity than the corresponding Dirichlet branch with an odd number of interior zeroes.

Finally, the Dirichlet branches with odd number of interior zeroes are all similar, since any two such branches are similar to a pair of Neumann branches, but Neumann branches are all similar.

The Dirichlet branches with even number of interior zeroes may behave differently, as the following example due to R. Schaaf [53] shows.

EXAMPLE [53]. For the problem

$$u'' + \lambda\left(e^u - 1\right) = 0 \quad \text{on } (0,1), \qquad u(0) = u(1) = 0$$

the branch bifurcating from the principal eigenvalue does not turn, while all other branches have exactly one turn.

3. A class of symmetric nonlinearities

For the autonomous equation (2.1) both phase-plane analysis and bifurcation theory apply. If we allow explicit dependence of the nonlinearity on x, i.e. consider

$$u'' + \lambda f(x,u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{3.1}$$

then the problem becomes much more complicated. For example, solutions of the corresponding linearized problem need not be of one sign. In the papers P. Korman and T. Ouyang a class of $f(x,u)$ has been identified, for which the theory of positive solutions is very similar to that for the autonomous case, see, e.g., [34–36]. Further results in this direction have been given in P. Korman, Y. Li and T. Ouyang [30], and P. Korman and J. Shi [40]. Namely, we assume that $f \in C^2$ satisfies

$$f(-x,u) = f(x,u) \quad \text{for all } -1 < x < 1 \text{ and } u > 0, \tag{3.2}$$

$$f_x(x,u) \leqslant 0 \quad \text{for all } 0 < x < 1 \text{ and } u > 0. \tag{3.3}$$

Under the above conditions any positive solution of (3.1) is an even function, with $u'(x) < 0$ for all $x \in (0,1]$, see B. Gidas, W.-M. Ni and L. Nirenberg [15]. (For the one-dimensional problem (3.1) a different proof of the symmetry of solutions is given in P. Korman [18]. It is a little simpler than the moving plane method of [15], and it allows to relax somewhat the condition (3.3).) As before the linearized problem

$$w'' + \lambda f_u(x,u)w = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0 \tag{3.4}$$

will be important for the multiplicity results.

LEMMA 3.1 [34]. *Under conditions* (3.2) *and* (3.3) *any nontrivial solution of* (3.4) *is of one sign. Moreover,* $w(x)$ *is an even function, and it spans the null set of* (3.4).

PROOF. Assume that $w(x)$ has a root on [0, 1) (the case when $w(x)$ vanishes on $(-1,0]$ is similar). We may assume (taking $-w$ if necessary) that there is a subinterval (x_1,x_2), $0 \leqslant x_1 < x_2 \leqslant 1$, so that $w(x)>0$ on (x_1,x_2), and $w(x_1)=w(x_2)=0$. Integrating the relation $[u'w'-u''w]'=\lambda f_x w$ over (x_1,x_2),

$$u'(x_2)w'(x_2)-u'(x_1)w'(x_1)=\lambda\int_{x_1}^{x_2} f_x w\,\mathrm{d}x.$$

We have a contradiction, since the quantity on the left is positive, while the one on the right is nonpositive.

The null set of (3.4) is one dimensional, since it can be parameterized by $w'(1)$. To prove that $w(x)$ is even, observe that $w(-x)$ is also a solution of (3.1), and hence $w(-x)=cw(x)$ for some constant c (since the null set of (3.4) is one dimensional). Evaluating this at $x=0$, we conclude that $c=1$ (since $w(0)>0$), and the claim follows. □

The next lemma shows that the Crandall–Rabinowitz Theorem 1.2 applies at any critical solution.

LEMMA 3.2. *Under conditions* (3.2) *and* (3.3) *let* $u(x)$ *be a critical solution of* (3.1), *and* $w(x)$ *a solution of the corresponding linearized problem. Then we have*

$$\int_0^1 f(x,u)w\,\mathrm{d}x > \frac{1}{2\lambda}u'(1)w'(1)>0. \tag{3.5}$$

PROOF. By the preceding lemma we may assume that $w(x)>0$. We then have

$$(u''w-u'w')'=-\lambda f_x w>0 \quad \text{for } x>0.$$

So that the function $u''w-u'w'$ is increasing on (0, 1), and then

$$u''w-u'w'<-u'(1)w'(1) \quad \text{for } x>0.$$

Integrating this over (0, 1), and expressing u'' from Eq. (3.1), we conclude (3.5). □

The following result from P. Korman and J. Shi [40] is an extension of Lemma 2.3. Unlike the autonomous case, several conditions are now needed.

THEOREM 3.1 See [40]. *In addition to* (3.2) *and* (3.3) *assume that*

$$f(x,u)>0 \quad \textit{for all } -1<x<1 \textit{ and } u>0. \tag{3.6}$$

Then the set of positive solutions of (3.1) *can be parameterized by their maximum values* $u(0)$. (*I.e.* $u(0)$ *uniquely determines the pair* $(\lambda,u(x))$.)

PROOF. Assume on the contrary $v(x)$ is another solution of (3.1), corresponding to some parameter $\mu \geqslant \lambda$, but $u(0) = v(0)$. The case of $\mu = \lambda$ is not possible in view of uniqueness of initial value problems, so assume that $\mu > \lambda$. Then $v(x)$ is a supersolution of (3.1), i.e.

$$v'' + \lambda f(x, v) < 0 \quad \text{for } -1 < x < 1, \qquad v(-1) = v(1) = 0. \tag{3.7}$$

Since $v''(0) < u''(0)$, it follows that $v(x) < u(x)$ for $x > 0$ small. Let $0 < \xi \leqslant 1$ be the first point where the graphs of $u(x)$ and $v(x)$ intersect (i.e. $v(x) < u(x)$ on $(0, \xi)$). We now multiply Eq. (3.1) by u', and integrate over $(0, \xi)$. Denoting by $x_2(u)$ the inverse function of $u(x)$ on $(0, \xi)$, we have

$$\frac{1}{2}u'^2(\xi) + \int_{u(0)}^{u(\xi)} f\big(x_2(u), u\big)\,\mathrm{d}u = 0. \tag{3.8}$$

Similarly denoting by $x_1(u)$ the inverse function of $v(x)$ on $(0, \xi)$, we have from (3.7)

$$\frac{1}{2}v'^2(\xi) + \int_{u(0)}^{u(\xi)} f\big(x_1(u), u\big)\,\mathrm{d}u > 0. \tag{3.9}$$

Subtracting (3.9) from (3.8), noticing that $x_2(u) > x_1(u)$ for all $u \in (u(\xi), u(0))$, and using condition (3.3), we have

$$\frac{1}{2}\big[u'^2(\xi) - v'^2(\xi)\big] + \int_{u(\xi)}^{u(0)} \big[f\big(x_1(u), u\big) - f\big(x_2(u), u\big)\big]\,\mathrm{d}u < 0. \tag{3.10}$$

Since both terms on the left are positive, we obtain a contradiction. □

Next we consider positive solutions of the boundary value problem

$$u'' + \lambda b(x) f(u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0. \tag{3.11}$$

We assume that $b(x) \in C^1[-1, 1]$ satisfies $b(x) > 0$ for $x \in [-1, 1]$, and $b(x) = b(-x)$, $b'(x) < 0$ for $x \in (0, 1)$. We also assume that $f(u) > 0$, so that this problem belongs to the class discussed above. For any solutions $u(x)$ let $(\mu, w(x))$ denote the principal eigenpair of the corresponding linearized equation, i.e. we assume that $w(x) > 0$ satisfies

$$\begin{aligned} &w'' + \lambda b(x) f'(u) w + \mu w = 0 \quad \text{for } -1 < x < 1, \\ &w(-1) = w(1) = 0. \end{aligned} \tag{3.12}$$

The following theorem is taken from P. Korman and J. Shi [40].

THEOREM 3.2. *Assume $f \in C^2[0, \infty)$, $f(u) > 0$, $f'(u) > 0$ and $f''(u) > 0$ for all $u > 0$, and for some $\alpha > 0$ condition* (2.43) *is satisfied. Then the solution of* (3.11) *with $u(0) = \alpha$ is unstable if it exists.*

PROOF. In the proof of Theorem 2.3, (2.25) and (2.26) are still true. Assume now that $u(x)$ is stable, i.e. $\mu \geqslant 0$ in (3.12). Then $w(x)$ is a positive solution of the problem

$$w'' + g(x, w) = 0 \quad \text{for } -1 < x < 1, \qquad w(-1) = w(1) = 0, \tag{3.13}$$

with $g(x, w) = \lambda b(x) f'(u(x))w + \mu w$. Since $g(x, w)$ is even in x, and

$$g_x = \lambda b'(x) f'(u)w + \lambda b(x) f''(u)u'w < 0 \quad \text{on } (0, 1),$$

the theorem of B. Gidas, W.-M. Ni and L. Nirenberg [15] applies to (3.13). It follows that $w(x)$ is an even function with $w'(x) < 0$ on $(0, 1)$. Recall that $w(x)$ is determined up to a constant multiple. Since $w(x)$ is decreasing, while $-u'(x)$ is increasing on $(0, 1)$, by scaling $w(x)$ we can achieve (2.28). Using (2.25), (2.28), and also (2.26), we have (2.29).

Since $b(x) > 0$, $b'(x) < 0$ in $(0, 1)$ using (2.25) and (2.29), we have

$$\begin{aligned}
&\int_0^1 b(x)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \\
&\quad = \int_0^{x_0} b(x)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \\
&\qquad + \int_{x_0}^1 b(x)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \\
&\quad < \int_0^{x_0} b(x_0)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \\
&\qquad + \int_{x_0}^1 b(x_0)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \\
&\quad = b(x_0)\int_0^1 \bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x \leqslant 0.
\end{aligned} \tag{3.14}$$

On the other hand, multiplying Eq. (3.12) by u, Eq. (3.1) by w, subtracting and integrating over $(0, 1)$, we have

$$\int_0^1 b(x)\bigl[f(u) - uf'(u)\bigr]w(x)\,\mathrm{d}x = \frac{\mu}{\lambda}\int_0^1 uw\,\mathrm{d}x \geqslant 0. \tag{3.15}$$

We reach a contradiction by combining (3.14) and (3.15). □

As an application we have the following exact multiplicity result from P. Korman and J. Shi [40]. It extends the corresponding result in [34] by not restricting the behavior of $f(u)$ at infinity. Theorem 3.1 above allows us to conclude the uniqueness of the solution curve.

THEOREM 3.3. *We assume that* $b(x) \in C^1[-1, 1]$ *satisfies* $b(x) > 0$ *for* $x \in [-1, 1]$, *and* $b(x) = b(-x)$, $b'(x) < 0$ *for* $x \in (0, 1)$. *Assume* $f \in C^2[0, \infty)$, $f(u) > 0$, $f'(u) > 0$ *and*

$f''(u) > 0$ *for all* $u > 0$, *while* $h(\alpha) \leqslant 0$ *for some* $\alpha > 0$. *Then there exist two constants* $0 \leqslant \bar{\lambda} < \lambda_0$, *so that problem* (3.11) *has no solution for* $\lambda > \lambda_0$, *exactly two solutions for* $\bar{\lambda} < \lambda < \lambda_0$, *and in case* $\bar{\lambda} > 0$ *it has exactly one solution for* $0 < \lambda < \bar{\lambda}$. *Moreover, all solutions lie on a unique smooth solution curve. If we moreover assume that* $\lim_{u\to\infty} \frac{f(u)}{u} = \infty$, *then* $\bar{\lambda} = 0$.

EXAMPLE. Theorem 3.3 applies (with $\bar{\lambda} = 0$) to an example from combustion theory

$$u'' + \lambda b(x)\mathrm{e}^u = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0,$$

where $b(x)$ satisfies the above conditions.

P. Korman and T. Ouyang [34] have considered a class of *indefinite* problems

$$\begin{aligned} &u''(x) + \lambda u(x) + h(x)u^p(x) = 0, \quad -1 < x < 1, \\ &u(-1) = u(1) = 0. \end{aligned} \tag{3.16}$$

Here $p > 1$, and λ a real parameter. The given function $h(x)$ is assumed to be even, and it is allowed to change sign on $(-1, 1)$. By using bifurcation analysis, as above, as well as earlier work of T. Ouyang [48,49], it was possible to give an exhaustive description of the set of positive solutions of (3.16).

We denote by $\phi_1 = \cos\frac{\pi}{2}x$, the principal eigenfunction of $-u''$ on $(-1, 1)$, corresponding to the principal eigenvalue $\lambda_1 = \frac{\pi^2}{4}$. We assume that $h(x) \in C^1(-1, 1) \cap C^0[-1, 1]$ is an even function, and moreover,

$$h(0) > 0, \quad \text{and} \quad h'(x) < 0 \quad \text{for } x \in (0, 1), \tag{3.17}$$

$$\int_{-1}^{1} h(x)\phi_1^{p+1}(x)\,\mathrm{d}x < 0. \tag{3.18}$$

(Notice that the last assumption implies that $h(x)$ changes sign.)

THEOREM 3.4 [34]. *Assume that conditions* (3.17) *and* (3.18) *hold for problem* (3.16). *Then there is a critical* λ_0, $\lambda_0 > \lambda_1$, *so that for* $-\infty < \lambda \leqslant \lambda_1$ *problem* (3.16) *has exactly one positive solution, it has exactly two positive solutions for* $\lambda_1 < \lambda < \lambda_0$, *exactly one at* $\lambda = \lambda_0$, *and no positive solutions for* $\lambda > \lambda_0$. *Moreover, all positive solutions lie on a unique continuous in* λ *curve, which bifurcates from zero at* $\lambda = \lambda_1$ (*to the right*), *it continues without any turns to* $\lambda = \lambda_0$, *at which it turns to the left, and then continues without any more turns for all* $-\infty < \lambda \leqslant \lambda_0$. *We also have* $\max_x u(x) \to \infty$ *as* $\lambda \to -\infty$.

As far as we know, this is still the only known exact multiplicity result for indefinite problems.

Let us mention next the cubic problems

$$\begin{aligned} &u'' + \lambda\big(u - a(x)\big)\big(u - b(x)\big)\big(c(x) - u\big) = 0 \quad \text{for } -1 < x < 1, \\ &u(-1) = u(1) = 0, \end{aligned} \tag{3.19}$$

with given even functions $0 \leqslant a(x) \leqslant b(x) \leqslant c(x)$. As we discussed above, for constant a, b and c, the exact multiplicity question has been settled only recently by P. Korman, Y. Li and T. Ouyang [33], via a computer assisted proof. One can expect that under some conditions the same global picture holds for variable coefficients. This was established for several special cases. P. Korman, Y. Li and T. Ouyang [30] have given an exact multiplicity result in case $a = b = 0$. P. Korman and T. Ouyang [36] had done the same in case $a = 0$, and P. Korman and T. Ouyang [38] had given an exact multiplicity result in case when $a > 0$ is a constant.

Next we indicate an extension. Consider a problem with a variable diffusion coefficient

$$\big(a(x)u'\big)' + \lambda f(u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0. \tag{3.20}$$

We assume that a given function $a(x) \in C^1[-1, 1]$ is even, and it satisfies

$$a(x) > 0 \quad \text{and} \quad xa'(x) \leqslant 0, \quad \text{for } x \in [-1, 1]. \tag{3.21}$$

We perform a change of variables $x \to s$, given by

$$s = \int_0^x \frac{\mathrm{d}t}{a(t)}.$$

If we denote by $s_0 = \int_0^1 \frac{\mathrm{d}t}{a(t)}$, then this transformation gives a one-to-one map of the interval $(-1, 1)$ onto $(-s_0, s_0)$. Moreover, $s > 0$ (< 0) iff $x > 0$ (< 0). The problems (3.20) transforms into

$$\begin{aligned} &u_{ss} + \lambda a\big(x(s)\big) f(u) = 0 \quad \text{for } -s_0 < x < s_0, \\ &u(-s_0) = u(s_0) = 0. \end{aligned} \tag{3.22}$$

Observe that the function $s = s(x)$ is odd, and hence its inverse $x = x(s)$ is also odd, and then $a(x(s))$ is even. In view of (3.21)

$$\frac{\mathrm{d}}{\mathrm{d}s} a\big(x(s)\big) = a'\big(x(s)\big) a\big(x(s)\big) \leqslant 0 \ (\geqslant 0) \quad \text{if } s > 0 \ (< 0).$$

If we now assume that $f(u) > 0$ for $u > 0$, then the problem (3.22) satisfies conditions (3.2) and (3.3). Hence, we can translate our results, in particular Theorem 3.3, to problem (3.20).

4. General nonlinearities

Without the symmetry assumptions on $f(x, u)$ the problem is much harder. We restrict to a subclass of such problems, i.e. we now consider positive solutions of the boundary value problem

$$u'' + \lambda \alpha(x) f(u) = 0 \quad \text{for } a < x < b, \qquad u(a) = u(b) = 0, \tag{4.1}$$

on an arbitrary interval (a, b). We assume that $f(u)$ and $\alpha(x)$ are positive functions of class C^2, i.e.

$$f(u) > 0 \quad \text{for } u > 0, \qquad \alpha(x) > 0 \quad \text{for } x \in [a, b]. \tag{4.2}$$

As before, it will be crucial for bifurcation analysis to prove positivity for the corresponding linearized problem

$$w'' + \lambda\alpha(x) f'(u)w = 0 \quad \text{for } a < x < b, \qquad w(a) = w(b) = 0. \tag{4.3}$$

The following result was proved in P. Korman and T. Ouyang [38], although our exposition here is a little different.

LEMMA 4.1. *In addition to conditions* (4.2), *assume that*

$$\frac{3}{2}\frac{\alpha'^2}{\alpha} - \alpha'' < 0 \quad \textit{for all } x \in (a, b). \tag{4.4}$$

If the linearized problem (4.3) *admits a nontrivial solution*, *then we may assume that* $w(x) > 0$ *on* (a, b).

PROOF. Let $z(x) = g(x)u'(x)$, with $g(x)$ to be chosen shortly. Then $z(x)$ satisfies the equation

$$z'' + \lambda\alpha(x) f'(u)z = g''(x)u'(x) - \lambda\big(2g'(x)\alpha(x) + \alpha'(x)g(x)\big) f.$$

We now chose $g(x) = \alpha(x)^{-1/2}$. Then $2g'(x)\alpha(x) + \alpha'(x)g(x) = 0$, while

$$g''(x) < 0 \quad \text{for } a < x < b, \tag{4.5}$$

in view of the condition (4.4).

Notice that any positive solution of (4.1) is a concave function, and hence it has only one critical point, the point of global maximum. Let x_0 be the point of maximum of $u(x)$. We have

$$z'' + \lambda\alpha(x) f'(u)z = g''(x)u'(x), \tag{4.6}$$

with the right-hand side negative on (a, x_0) and positive on (x_0, b). This will make it impossible for $w(x)$ to vanish inside (a, b). Indeed, if we assume that $w(x)$ vanishes on say (x_0, b), we could find two consecutive roots of $w(x)$, $x_0 \leqslant x_1 < x_2 \leqslant b$ so that $w(x_1) = w(x_2) = 0$, while $w(x) > 0$ on (x_1, x_2). We now multiply the equation (4.6) by $w(x)$, Eq. (4.3) by $z(x)$, subtract and integrate over (x_1, x_2), obtaining

$$-g(x_2)u'(x_2)w'(x_2) + g(x_1)u'(x_1)w'(x_1) = \int_{x_1}^{x_2} g''(x)u'(x)w(x)\,\mathrm{d}x.$$

We have a contradiction, since the quantity on the left is negative, and the integral on the right is positive. □

REMARKS.

1. Recall the Schwarzian derivative from Complex Analysis and Dynamical Systems

$$(Sf)(x) = \frac{f'''(x)}{f'(x)} - \frac{3}{2}\left(\frac{f''(x)}{f'(x)}\right)^2.$$

   If one denotes $A(x) = \int \alpha(x)\,\mathrm{d}x$, then our condition (4.4) says that the Schwarzian derivative of $A(x)$ is positive.
2. Semilinear equations on an annulus in $\mathbb{R}^n$, $n > 2$, can be reduced by a standard change of variables to the problem (4.1), with $\alpha(x) = x^{-2k}$ and $k = 1 + \frac{1}{n-2}$, see, e.g., [19]. One sees that our condition (4.4) just misses this kind of functions. In [19] positivity of $w(x)$ was proved under an extra assumption that the annulus is "thin".

We shall present a new result on positivity of $w(x)$, after we prove a simple lemma.

LEMMA 4.2. *Assuming conditions* (4.2), *let* x_0 *be the unique point of maximum of the positive solution of* (4.1). *Assume that*

$$\alpha'(x) < 0 \quad \text{on } (x_0, b). \tag{4.7}$$

If the corresponding linearized problem (4.3) *admits a nontrivial solution* $w(x)$, *then this solution cannot vanish inside* (x_0, b).

PROOF. Assuming the contrary, let γ be the largest root of $w(x)$ on (x_0, b), and assume that $w(x) > 0$ on (γ, b). (The number of roots of $w(x)$ inside (a, b) is at most finite, as follows by the Sturm's comparison theorem, since both functions $f'(u(x))$ and $\alpha(x)$ are bounded on $[a, b]$, and λ is fixed. Hence, there is a largest root γ.) Differentiate Eq. (4.1)

$$u_x'' + \lambda\alpha(x) f'(u)u_u + \lambda\alpha'(x) f(u) = 0. \tag{4.8}$$

Multiplying Eq. (4.8) by $w(x)$, Eq. (4.3) by $u'(x)$, subtracting and integrating, we have

$$-u'(b)w'(b) + u'(\gamma)w'(\gamma) + \lambda\int_\gamma^b \alpha'(x) f\big(u(x)\big)w(x)\,\mathrm{d}x = 0.$$

This results in a contradiction, since all terms on the left are negative. □

REMARK. If $\alpha'(x) > 0$ on (a, x_0), then a similar proof shows that $w(x)$ cannot vanish inside (a, x_0).

LEMMA 4.3. *Assume conditions* (4.2) *hold*, *and in addition assume that*

$$\alpha'(x) < 0 \quad \text{on } (a, b), \tag{4.9}$$

and

$$2\alpha(x) + x\alpha'(x) > 0 \quad \text{on } (a,b). \tag{4.10}$$

If the linearized problem (4.3) *admits a nontrivial solution, then we may assume that* $w(x) > 0$ *on* (a,b).

PROOF. Let x_0 be the unique point of maximum of the solution $u(x)$. By the previous Lemma 4.2 it follows that $w(x)$ cannot vanish on (x_0, b). Assuming that $w(x)$ vanishes on $(a, x_0]$, let $\gamma \in (a, x_0]$ be the first root of $w(x)$, and we may assume that $w(x) > 0$ on (a, γ). We consider the function $\zeta(x) = x[u'(x)w'(x) + \lambda\alpha(x) f(u(x))w(x)] - u'(x)w(x)$, introduced by M. Tang [58]. One computes

$$\zeta'(x) = \lambda\big[2\alpha(x) + x\alpha'(x)\big] f(u)w. \tag{4.11}$$

Integrating over (a, γ),

$$\gamma u'(\gamma)w'(\gamma) - au'(a)w'(a) = \lambda \int_a^\gamma \big[2\alpha(x) + x\alpha'(x)\big] f(u)w \,\mathrm{d}x.$$

We have a contradiction, since the quantity on the left is negative, while the integral on the right is positive. □

REMARK. Our condition (4.10) again just misses the case of an annulus.

Positivity of $w(x)$ can be used to prove uniqueness and exact multiplicity results. For example, we can prove the following theorem.

THEOREM 4.1. *For problem* (4.1) *assume that conditions* (4.2) *hold, and that either condition* (4.4) *holds, or conditions* (4.9) *and* (4.10) *hold. In addition assume that* $f''(u) > 0$ *for all* $u > 0$, *and* $\lim_{u\to\infty} \frac{f(u)}{u} = \infty$. *Then there is a critical* $\lambda_0 > 0$, *so that problem* (4.1) *has exactly two positive solutions for* $0 < \lambda < \lambda_0$, *exactly one positive solution at* $\lambda = \lambda_0$, *and no positive solutions for* $\lambda > \lambda_0$. *Moreover, all solutions lie on a unique smooth solution curve, which starts at* $(\lambda = 0, u = 0)$, *bends back at* $\lambda = \lambda_0$, *and tends to infinity as* $\lambda \to 0$.

PROOF. The proof is similar to that of Theorem 2.2, except for proving the uniqueness of the solution curve (since the maximum value of the solution no longer identifies that solution). However, if another solution curve existed, one of its ends would have to go through the point $(\lambda = 0, u = 0)$, contradicting the uniqueness of solutions near regular points, which follows by the implicit function theorem. (Since $w > 0$ at the turning point, one of the branches is increasing in λ, i.e. it is decreasing for decreasing λ. By the arguments of [34], or [35], the monotonicity is preserved along the branch, and hence this branch must go into the origin, as $\lambda \to 0$.) □

EXAMPLE. The theorem applies to the problem

$$u'' + \lambda\alpha(x)e^u = 0, \quad a < x < b, \qquad u(a) = u(b) = 0,$$

if $\alpha(x) > 0$ satisfies either condition (4.4), or conditions (4.9) and (4.10).

5. Time maps

5.1. *There are several different formulas for the time map*

Let $u = u(t)$ be solution of the initial value problem,

$$u'' + f(u) = 0, \qquad u(0) = 0, \quad u'(0) = p.$$

Using ballistic analogy, we can interpret this as "shooting" from the ground level, at an angle $p > 0$. Let $T/2$ denote the time it takes for the projectile to reach its maximum amplitude α, $\alpha = \alpha(p)$. By symmetry of positive solutions, $T = T(p)$ is then the time when the projectile falls back to the ground, the *time map*. Since the energy is constant (as before, $F(u) = \int_0^u f(t)\,dt$)

$$\frac{1}{2}\left(\frac{du}{dt}\right)^2 + F\big(u(t)\big) = F(\alpha) = \frac{1}{2}p^2.$$

Solving this for $\frac{dt}{du}$, and integrating

$$T/2 = \frac{1}{\sqrt{2}}\int_0^{\alpha} \frac{du}{\sqrt{F(\alpha) - F(u)}}, \tag{5.1}$$

which lets us compute $T = T(\alpha)$ (or $T = T(p)$, since $\alpha = \alpha(p)$). This formula has been used extensively for a long time, see, e.g., W.S. Loud [43], T. Laetsch [41], K.J. Brown et al. [9], J. Smoller and A. Wasserman [57], S.-H. Wang [59–61], I. Addou [1,2], I. Addou and S.-H. Wang [3], S.-H. Wang and T.S. Yeh [63], and J. Cheng [10,11]. It is not easy to use this formula. The integral is improper at $u = \alpha$, so that one needs a regularizing substitution before differentiating in α. One regularizing substitution is $u = \alpha \sin\theta$, which gives

$$T/2 = \frac{\alpha}{\sqrt{2}}\int_0^{\pi/2} \frac{\cos\theta\,d\theta}{\sqrt{F(\alpha) - F(\alpha\sin\theta)}}. \tag{5.2}$$

The integrand is now bounded. Formula (5.2) can be used for numerical computations, as well as for proving theorems. For more information we refer the reader to the above mentioned papers, particularly to the recent papers of S.-H. Wang and his coworkers.

5.2. *Time map formula through global linearization*

We are interested in positive solutions of the two point problem for $u = u(t)$

$$u'' + f(u) = 0, \quad 0 < t < T, \qquad u(0) = u(T) = 0. \tag{5.3}$$

We do not consider the end point T to be fixed, but rather depending on $p = u'(0)$ (or on the maximum value of the solution α, $\alpha = u(T/2)$). To obtain the formula for $T = T(p)$, we begin by transforming (5.3) into the system form

$$\begin{aligned} u' &= y, \\ y' &= -f(u), \end{aligned} \tag{5.4}$$

together with the initial conditions

$$u(0) = 0, \quad y(0) = p. \tag{5.5}$$

Let $F(u) = \int_0^u f(t)\,\mathrm{d}t$. In the linear case when $f(u) = u$, we have $F(u) = \frac{1}{2}u^2$. We now define the function $g(x)$, for $x \geqslant 0$, by

$$F\bigl(g(x)\bigr) = \frac{1}{2}x^2. \tag{5.6}$$

In other words, $g(x) = F^{-1}(\frac{1}{2}x^2)$, and the inverse function F^{-1} is defined, provided we assume throughout this section that $f(u) \in C^2(0,a) \cap C[0,a]$ for some $0 < a \leqslant \infty$, and

$$f(u) > 0 \quad \text{for } u \in (0,a). \tag{5.7}$$

We assume also that

$$\text{either } f(0) > 0, \quad \text{or} \quad f(0) = 0 \text{ and } f'(0) > 0. \tag{5.8}$$

Differentiate (5.6)

$$f\bigl(g(x)\bigr)g'(x) = x. \tag{5.9}$$

In (5.4) we let $u = g(x)$, then multiply the second equation by $g'(x)$, and use (5.9)

$$\begin{aligned} g'(x)x' &= y, \\ g'(x)y' &= -f\bigl(g(x)\bigr)g'(x) = -x. \end{aligned} \tag{5.10}$$

We now change the independent variable in (5.10), $t \to \theta$, by solving

$$\frac{\mathrm{d}t}{\mathrm{d}\theta} = g'\bigl(x(t)\bigr), \qquad t(0) = 0. \tag{5.11}$$

Then the system (5.4) is linearized, and problem (5.4), (5.5) transforms into

$$\begin{aligned}
&\frac{\mathrm{d}x}{\mathrm{d}\theta} = y,\\
&\frac{\mathrm{d}y}{\mathrm{d}\theta} = -x,\\
&x(0) = 0, \quad y(0) = p.
\end{aligned} \tag{5.12}$$

Solution of (5.12) is

$$x = p\sin\theta, \quad y = p\cos\theta.$$

Using this in (5.11) and integrating, we have the formula for the time map

$$T = \int_0^{\pi} g'(p\sin\theta)\,\mathrm{d}\theta. \tag{5.13}$$

This formula was derived by R. Schaaf [53], and was used by her to obtain a number of uniqueness and multiplicity results.

Separating variables in (5.11) and integrating

$$\int_0^T \frac{f(g(x(t)))}{x(t)}\,\mathrm{d}t = \pi, \tag{5.14}$$

where we have used (5.9) to express g'. From the definition of $g(x)$ we have

$$x = \sqrt{2F(g(x))} = \sqrt{2F(u)},$$

and hence we can rewrite (5.14) as

$$\int_0^T \frac{f(u(t))}{\sqrt{F(u(t))}}\,\mathrm{d}t = \sqrt{2}\pi. \tag{5.15}$$

This formula was derived in a different way by P. Korman and Y. Li [28], where the quantity on the left was referred to as "generalized average" of the solution of (5.3). The reason why this term was chosen is that in case $f(u) = u^3$, this formula gives the average value of the solution: $\int_0^T u(t)\,\mathrm{d}t = \frac{\pi}{\sqrt{2}}$.

REMARKS.

1. We needed the positivity of $f(u)$ so that the inverse function F^{-1} is defined, however there is no need to distinguish between $f(0) = 0$ and $f(0) > 0$ cases for both formulas (5.13) and (5.15). In case $f(0) > 0$ the integral in (5.15) (and in (5.14)) is improper at both end points, however since $u'(0) \neq 0$ and $u'(T) \neq 0$, the integral converges. (For small t, $u(t) \sim u'(0)t$, $F(u(t)) \sim f(0)u(t) \sim f(0)u'(0)t$.)

2. Similarly, in the derivation of the time map formula (5.13), we run into an improper integral in case $f(0) > 0$. Indeed, when solving for $\theta = \theta(t)$ in (5.11), we have $\theta = \int_0^t \frac{\mathrm{d}s}{g'(x(s))}$, which is an improper integral at $s = 0$. However, as we have just seen, it is a convergent integral. Hence the time map formula in (5.13) is valid in both cases $f(0) = 0$, and $f(0) > 0$.
3. Let us collect the properties of the function $g(x)$. We have $g(0) = 0$, $g'(x) = \frac{\sqrt{2F(g(x))}}{f(g(x))} > 0$ for $x > 0$. We also have $g'(0) = 0$ in case $f(0) > 0$, and, by L'Hopital's rule as was observed in R. Schaaf [53], $g'(0) = \frac{1}{\sqrt{f'(0)}}$ in case $f(0) = 0$. Observe that $g'(0)$ is defined, thanks to condition (5.8).

It is sometimes more convenient to express $T = T(\alpha)$, where α is the maximum value of the solution, $\alpha = u(T/2)$. Since the energy $\frac{1}{2}u'^2(x) + F(u(x))$ is constant, it follows that $p = \sqrt{2F(\alpha)}$, and hence

$$T/2 = \int_{\pi/2}^{\pi} g'(p\sin\theta)\,\mathrm{d}\theta = \int_0^{\pi/2} g'\Bigl(\sqrt{2F(\alpha)}\cos\theta\Bigr)\,\mathrm{d}\theta. \tag{5.16}$$

$T/2$ is, of course, the time it takes the solution to travel from its maximum to zero.

EXAMPLE. Consider the problem ($u = u(x)$)

$$u'' + \lambda \mathrm{e}^u = 0, \quad x \in (0,1), \qquad u(0) = u(1) = 0. \tag{5.17}$$

By a change of independent variable we convert it to

$$u'' + \mathrm{e}^u = 0, \quad x \in (0,1), \qquad u(0) = u(T) = 0, \tag{5.18}$$

where $T = \sqrt{\lambda}$. Here $f(u) = \mathrm{e}^u$, $F(u) = \mathrm{e}^u - 1$, and $g(x) = \ln(\frac{1}{2}x^2 + 1)$. The integral in (5.16) is then relatively simple, and in fact *Mathematica* gives

$$\sqrt{\lambda}/2 = \sqrt{\frac{2}{\mathrm{e}^\alpha}}\,\mathrm{ArcTanh}\left[\sqrt{\frac{\mathrm{e}^\alpha - 1}{\mathrm{e}^\alpha}}\right]. \tag{5.19}$$

Plotting this formula (with λ along the horizontal axis and α along the vertical one), we obtain the same bifurcation diagram as obtained by standard integration. Computation this way is considerably faster than by integration, and we also observe that here $f(0) > 0$. Formula (5.19) can also be obtained by explicit integration of problem (5.17).

We can proceed similarly for the general case

$$u'' + \lambda f(u) = 0, \quad x \in (0,1), \qquad u(0) = u(1) = 0. \tag{5.20}$$

We do not have a simple formula for $g(x)$ anymore, however from (5.16) (see also (5.9)) we obtain (as before, $T = \sqrt{\lambda}$)

$$\sqrt{\lambda}/2 = \int_0^{\pi/2} \frac{\sqrt{2F(\alpha)}\cos\theta}{f(F^{-1}(F(\alpha)\cos^2\theta))}\,\mathrm{d}\theta. \tag{5.21}$$

This formula will provide probably one of the most efficient ways to compute the bifurcation diagrams, once the evaluation of the inverse function F^{-1} is numerically implemented.

Assume now there is an $a > 0$, so that $f(a) = 0$, and $f(u) > 0$ for $u > a$, while no assumptions on the sign of $f(u)$ are made when $u \in (0, a)$. If we denote by $T_1/2$ the time it takes the solution to travel from its maximum to $u(x) = a$, then

$$T_1/2 = \int_{\theta_0}^{\pi/2} g'\Big(\sqrt{2F(\alpha)}\cos\theta\Big)\,\mathrm{d}\theta, \quad \text{where } \theta_0 = \sin^{-1}\sqrt{\frac{F(a)}{F(\alpha)}}. \tag{5.22}$$

The following theorem we proved in [27].

THEOREM 5.1. *Assume that for some* $0 < a < b \leqslant \infty$ *we have*

$$f(u) > 0 \quad \textit{for } a < u < b, \tag{5.23}$$

$$f'(u)\int_a^u f(t)\,\mathrm{d}t - \frac{1}{2}f^2(u) > 0 \quad \textit{for } a < u < b. \tag{5.24}$$

(*Observe that we implicitly assume that* $f(a) = 0$.) *Then the problem*

$$u'' + f(u) = 0, \quad x \in (0,1), \qquad u(0) = u(1) = 0$$

has at most one positive solution, *with* $a < \alpha = u(1/2) < b$.

What is remarkable here is than no assumptions whatsoever are made on $f(u)$ when $u \in (0, a)$. We used generalized averages to prove this result, but it should be possible to obtain it from formula (5.22) too. In fact, there is a similar result in R. Schaaf's book [53] (a little less general than the above theorem). Observe that (5.24) will follow if $f(a) = 0$ and $f''(u) > 0$ for $a < u < b$. A more general result for p-Laplacian case has been given recently by J. Cheng [10].

We now show how the time map formula gives rise to uniqueness and multiplicity results for the Dirichlet problem. Compute

$$\frac{\mathrm{d}T}{\mathrm{d}p} = \int_0^{\pi} g''(p\sin\theta)\sin\theta\,\mathrm{d}\theta, \tag{5.25}$$

where $g''(x)$ is computed from (5.9) (written in the form $g'(x) = \frac{\sqrt{2F(u)}}{f(u)}$, $u = g(x)$)

$$g''(x) = \frac{f^2 - 2Ff'}{f^3}(u), \quad \text{with } u = g(x). \tag{5.26}$$

If the time map $T(p)$ is monotone, then clearly the positive solution of the Dirichlet problem (5.3) for any *fixed* T is unique. Hence, we have uniqueness of solutions if either

$$I(u) \equiv f'(u)F(u) - \frac{1}{2}f^2(u) > 0 \quad \text{for almost all } u > 0, \tag{5.27}$$

or the opposite inequality holds. This condition was derived by R. Schaaf [53], and it also follows from the generalized averages in [28].

We observe next that this condition does not add anything to the standard uniqueness condition

$$uf'(u) - f(u) \quad \text{does not change sign for } u > 0. \tag{5.28}$$

I.e. (5.28) holds whenever (5.27) does, and so condition (5.28) is both simpler and more general.

Indeed, we begin by observing

$$\frac{\mathrm{d}^2}{\mathrm{d}u^2}\Bigl(\sqrt{F(u)}\Bigr) = \frac{I(u)}{2F^{3/2}(u)} \equiv J(u),$$

where $J(u)$ has the same sign as $I(u)$. Integrating between some $a > 0$ and $u > 0$,

$$\frac{\mathrm{d}}{\mathrm{d}u}\Bigl(\sqrt{F(u)}\Bigr) = \int_a^u J(\xi)\,\mathrm{d}\xi + c > 0, \tag{5.29}$$

where $c = \frac{f(a)}{2\sqrt{F(a)}} > 0$. Integrating (5.29),

$$\sqrt{F(u)} = cu + c_1 + \int_a^u (u-\xi)J(\xi)\,\mathrm{d}\xi, \tag{5.30}$$

where $c_1 = -\int_0^a \xi J(\xi)\,\mathrm{d}\xi$. From (5.30) we find $F(u)$, and then $f(u)$ and $f'(u)$ by differentiation. We then have

$$uf'(u) - f(u) = 2\sqrt{F(u)}J(u)u + 2\int_0^u \xi J(\xi)\,\mathrm{d}\xi\left(\int_a^u J(\xi)\,\mathrm{d}\xi + c\right).$$

In view of (5.29), the quantity in the bracket is positive, and it follows that if $J(u)$ is positive (negative), so is $uf'(u) - f(u)$.

We now consider the problem

$$u'' + \lambda f(u) = 0, \quad x \in (0,1), \qquad u(0) = u(1) = 0, \tag{5.31}$$

depending on a positive parameter λ. As before, we can convert it to problem (5.3), with $T = \sqrt{\lambda}$. If we can show that $T''(p) > 0$ (or $T''(p) < 0$) for all $p > 0$, it will follow that for any λ there is at most two p's with $T(p) = \sqrt{\lambda}$, i.e. at most two solutions of (5.31). Since

$$T''(p) = \int_0^\pi g'''(p\sin\theta)\sin^2\theta\,\mathrm{d}\theta,$$

it suffices to show that the function $g'''(u)$ keeps the same sign. By formula (1-1-15) in R. Schaaf [53]

$$g'''(u) = -g'(x)\frac{3f'(u)(f^2(u) - 2F(u)f'(u)) + 2F(u)f(u)f''(u)}{f^4(u)},$$
$$\text{with } u = g(x),$$

which led her to the following condition: if

$$3f'(u)\bigl(f^2(u) - 2F(u)f'(u)\bigr) + 2F(u)f(u)f''(u) > 0 \text{ (or } < 0),$$
$$\text{for all } u > 0 \tag{5.32}$$

then problem (5.31) has at most two positive solutions. Since condition (5.32) is not easy to verify, R. Schaaf [53] went on to develop her $A - B$ and C conditions, which are sufficient for (5.32) to hold.

Condition (5.32) says that $g'(u)$ is either convex or concave. Working with the generalized averages, P. Korman and Y. Li [28] have shown that the same result is true if $\frac{1}{g'(u)}$ is convex (also in the case $\frac{1}{g'(u)}$ concave, but this possibility is included in the case when $g'(u)$ is concave). This led them to the following condition: if

$$\frac{1}{2}f''(u)F^2(u) + \frac{3}{8}f^3(u) - \frac{3}{4}f(u)f'(u)F(u) > 0 \quad \text{for all } u > 0, \tag{5.33}$$

then problem (5.31) has at most two positive solutions. Observe that this condition is different from (5.32). Conditions (5.32) and (5.33) work in both cases $f(0) = 0$ and $f(0) > 0$. Also, computer algebra can help in verifying these conditions.

EXAMPLE. The function $f(u) = 2 + e^{-u}\sin u$ satisfies (5.33). This function changes concavity infinitely many times. A straightforward computation, using *Mathematica*, shows that for this function the left-hand side of (5.33) is positive, tending to 10.125 as $u \to \infty$. Hence, problem (5.31) with this $f(u)$ has at most two positive solutions for any $\lambda > 0$.

REMARKS.

1. The time map formula can be also developed for the p-Laplacian case. Actually, even more general case is developed in Section 2.5 of R. Schaaf's book [53].
2. Finally, we mention why we constantly stress that all results about the time map hold in both cases $f(0) = 0$ and $f(0) > 0$. The important book by R. Schaaf [53] treats the $f(0) = 0$ case in Chapter 1, while the case $f(0) > 0$ (and also the case $f(0) < 0$) is postponed to Chapter 3. Some readers might form an incorrect impression that the book covers only the $f(0) = 0$ case (as in the MathSciences Review of that book).

5.3. *Variational formula for the time map*

In addition to the two formulas for the time map, discussed above, a curious variational formula has been discovered by R. Benguria and M.C. Depassier, see [8], which has also references to their earlier papers. If $u(t)$ is a solution of

$$u'' + \lambda f(u) = 0, \quad 0 < t < 1, \qquad u(0) = \alpha, \quad u'(0) = u(1) = 0, \tag{5.34}$$

it is shown by R. Benguria and M.C. Depassier that

$$\lambda = \max_{g \in D} \frac{1}{2} \frac{(\int_0^\alpha g'(y)^{1/3}\,\mathrm{d}y)^3}{\int_0^\alpha f(y)g(y)\,\mathrm{d}y},$$

where $D = \{g | g \in C^1(0, \alpha), g' > 0, g(0) = 0\}$. By rescaling, this formula is of course equivalent to a time map formula. It was used in [8] to obtain lower and upper bounds for time maps.

5.4. *A nonlocal problem*

Using the generalized inverses, we now give a complete description of the solution set of a nonlocal problem. We begin with a simple observation. It is well known that for any $L > 0$ the problem (here $u = u(x)$)

$$u'' + u^3 = 0, \quad 0 < x < L, \qquad u(0) = u(L) = 0$$

has a unique positive solution, and a unique negative solution. If we now take a positive solution on the interval $(0, L/k)$, followed by the negative solution on $(L/k, 2L/k)$, and so on, then we obtain a solution with $k - 1$ sign changes, for any positive integer k.

We now consider a nonlocal problem, where instead of a second boundary condition we prescribe the average value of the solution on some fixed interval $(0, L)$

$$\begin{aligned} &u'' + u^3 = 0, \quad 0 < x < L, \\ &u(0) = 0, \\ &\int_0^L u(s)\,\mathrm{d}s = \alpha, \end{aligned} \tag{5.35}$$

where α is a prescribed constant. We are interested in both positive, negative and sign-changing solutions, i.e. we shall talk of solutions with k sign changes, where $k \geqslant 0$. Without loss of generality we may assume $\alpha \geqslant 0$ (otherwise, consider $v = -u$). If $\alpha = 0$, it is clear that there exists exactly two solution of (5.35) with k sign changes, for any odd $k \geqslant 1$. Indeed, a solution of Eq. (5.35) with $u(0) = u(L) = 0$ having an odd number of roots inside $(0, L)$, and its negative, provide the desired solutions of (5.35). So that we may assume $\alpha > 0$.

THEOREM 5.2 [27]. *For any* $0 < \alpha < \frac{\pi}{\sqrt{2}}$ *there exists exactly one solution of* (5.35) *with k sign changes, for any* $k \geqslant 0$. *For* $\alpha = \frac{\pi}{\sqrt{2}}$ *there exists exactly one solution with k sign changes, for any even* $k \geqslant 0$, *and no solutions if k is odd. For any* $\alpha > \frac{\pi}{\sqrt{2}}$ *problem* (5.35) *has no solutions.*

PROOF. The problem "scales right". Setting $x = bt$, and $u = \frac{1}{b}v$, we see that $v = v(t)$ satisfies

$$
\begin{aligned}
&v'' + v^3 = 0, \quad 0 < t < \frac{L}{b}, \\
&v(0) = 0, \\
&\int_0^{L/b} v(s)\,\mathrm{d}s = \alpha.
\end{aligned}
\tag{5.36}
$$

Comparing with (5.35), we see that only the length of the interval has changed. Hence we have a one-to-one map between the solution sets on any two intervals. So consider a solution $U(x)$ of the equation $u'' + u^3 = 0$, with $u(0) = 0$, which has k sign changes, whose roots are $x = 1, 2, \ldots$, and such that $U(x) > 0$ on $(0, 1)$, $U(x) < 0$ on $(1, 2)$, and so on. According to formula (5.15), the integral of $U(x)$ over any of its positive humps is equal to $\frac{\pi}{\sqrt{2}}$, while the integral of $U(x)$ over any of its negative humps is $-\frac{\pi}{\sqrt{2}}$. Imagine cutting this solution with a sliding vertical line $x = \xi$. By continuity, for any $\alpha \in (0, \frac{\pi}{\sqrt{2}}]$ we can find a unique $\xi \in (0, 1]$ so that $U(x)$ is positive solution of (5.35) on the interval $(0, \xi)$. We then map this solution to the original interval $(0, L)$ by the above transformation. Similarly, for any $\alpha \in (0, \frac{\pi}{\sqrt{2}})$ we can find a unique $\xi \in (1, 2)$ so that we have a solution of (5.35) on the interval $(0, \xi)$, with exactly one sign change. We then map $U(x)$ to the original interval, as before. Similarly we construct solutions with arbitrarily many sign changes.

By (5.15), no solution is possible in case $\alpha > \frac{\pi}{\sqrt{2}}$. □

6. Numerical computation of solutions

Good analytical understanding of a problem goes hand in hand with efficient numerical calculation of its solution. We know that for positive solutions the maximum value $u(0) = \alpha$ uniquely determines the solution pair $(\lambda, u(x))$ of the problem

$$
u'' + \lambda f(u) = 0 \quad \text{for } -1 < x < 1, \qquad u(-1) = u(1) = 0, \tag{6.1}
$$

see Lemma 2.3 above. We also know that the parameter λ in (6.1) can be "scaled out", i.e. $v(x) \equiv u(\frac{1}{\sqrt{\lambda}}x)$ solves the equation $v'' + f(v) = 0$, while $v(0) = u(0) = \alpha$, and $v'(0) = u'(0) = 0$. The root of $v(x)$ is $r = \sqrt{\lambda}$. We therefore solve the initial value problem

$$
v'' + f(v) = 0, \qquad v(0) = \alpha, \quad v'(0) = 0, \tag{6.2}
$$

```
Clear ["Global`*"]
f[u_] = Exp [5u/(5+u)];
t = {};
Δα = 0.2; α0 = 0; nsteps = 150;
Do[up = α0 + j * Δα;
  If[(NIntegrate[f[t], {t, 0, up}] > 0 && f[up] > 0),
    α[j] = α0 + j * Δα;
    Int[θ_] := NIntegrate[f[u], {u, α[j] Sin[θ], α[j]}];
    λ[j] = 2 α[j]^2 (NIntegrate[Cos[θ]/√Int[θ], {θ, 0, Pi/2}])^2;
    t = Append[t, {λ[j], α[j]}]
  ]
  , {j, 1, nsteps}
]
ListPlot[t , PlotJoined → True,
  AxesLabel → {"Lambda", "u(0)"}, PlotLabel → "f(u)=Exp(5u/(5+u))"]
```

and find its first positive root r. Then $\lambda = r^2$ by the above remarks. This way for each α we can find the corresponding λ. After we choose sufficiently many α_n and compute the corresponding λ_n, we can plot the pairs (λ_n, α_n), obtaining a bifurcation diagram in (λ, α) plane. We stress that the resulting two-dimensional bifurcation curve gives a faithful representation of the solution set of (6.1), since the value $u(0) = \alpha$ uniquely determines the solution pair $(\lambda, u(x))$. The program for solving (6.1) is essentially one short loop, involving the **NDSolve** command in *Mathematica*. It can be found at the author's webpage: http://math.uc.edu/~kormanp/.

An equally good way to do numerical computations is by direct integration. For problem (6.2) we have $r = T/2$, where as before r is the first positive root, and T is the time map. I.e. $\lambda = T^2/4$. Using formula (5.2) for the time map, we have

$$\lambda = \frac{1}{2}\alpha^2 \left(\int_0^{\pi/2} \frac{\cos\theta}{\sqrt{\int_{\alpha\sin\theta}^{\alpha} f(u)\,\mathrm{d}u}}\,\mathrm{d}\theta \right)^2. \tag{6.3}$$

The *Mathematica* program based on (6.3) is so short and simple, that we include its listing here. It solves problem (6.1) for $f(u) = \mathrm{e}^{5u/(5+u)}$, and produces an S-shaped bifurcation curve, in agreement with our results. (Our program is solving the Dirichlet problem on the interval (0, 1), rather than (−1, 1), which accounts for the extra factor of 4.)

We see absolutely no need to ever use finite differences (or finite elements) for problem (6.1). If we divide the interval (0, 1) into n pieces, with step $h = 1/n$ and subdivision points $x_i = ih$, and denote by u_i the numerical approximation of $u(x_i)$, the finite difference approximation of (6.1) is

$$\frac{u_{i+1} - 2u_i + u_{i-1}}{h^2} + \lambda f(u_i) = 0, \quad 1 \leqslant i \leqslant n-1, \qquad u_0 = u_n = 0. \tag{6.4}$$

This is a system of *nonlinear* algebraic equations, more complicated in every way than the original problem (6.1). In particular, this system often has more solutions than the corresponding differential equation (6.1). The existence of the extra solutions (not corresponding to the solutions of (6.1)) has been recognized for a while, and a term *spurious* *solutions* has been used. For example in case $f(u) = \mathrm{e}^u$ the solution curve of (6.1) has exactly one turn (as we proved before), while the solution curve of (6.4) has three turns, see P. Korman [25]. Increasing the number of subdivision points n does not remove the two spurious turns, it just moves them closer to $\lambda = 0$. Actually the spurious turns are avoided in the opposite direction, when $n \leqslant 6$. We found this hard to prove, even when $n = 2$. When studying problem (6.4), we can no longer rely on the familiar tools from differential equations. Even in the case $f(u) = u^k$ the analysis of problem (6.4) is very involved, see E.L. Allgower [4].

For the general problem (1.1) (with $f = f(x, u)$) we suggest using the predictor-corrector method. If solution $u(x, \lambda)$ is known, one approximates

$$u(x, \lambda + \Delta\lambda) \simeq u(x, \lambda) + u_\lambda(x, \lambda)\Delta\lambda, \tag{6.5}$$

and then a very accurate approximation of $u(x, \lambda + \Delta\lambda)$ can be usually obtained in around 4 steps of Newton's iteration, with the initial guess given by (6.5). This way we can continue the solution in λ. To find $u_\lambda(x, \lambda)$ one solves a linear problem

$$\begin{aligned} &u_\lambda'' + f_u(x, u)u_\lambda + f(x, u) = 0 \quad \text{for } -1 < x < 1, \\ &u_\lambda(-1) = u_\lambda(1) = 0. \end{aligned} \tag{6.6}$$

To solve (6.6) one uses finite differences. (There are no spurious solutions for linear problems!) The resulting tri-diagonal system is easily solved by Gaussian elimination.

Abstract

In this text we investigate solvability of various nonlinear singular boundary value problems for ordinary differential equations on the compact interval $[0, T]$. The nonlinearities in differential equations may be singular both in the time and space variables. Location of all singular points in $[0, T]$ need not be known.

The work is divided into 6 sections. Sections 1 and 2 are devoted to singular higher order boundary value problems. The remaining ones deal with the second order case. Motivated by various applications in physics we admit here the left-hand sides of the equations under consideration containing the ϕ-Laplacian or p-Laplacian operator. The special attention is paid to Dirichlet and periodic problems.

Usually, the main ideas of the proofs of the results mentioned are described. More detailed proofs are included in the cases where no proofs are available in literature or where the details are needed later.

0. Notation

Let $J \subset \mathbb{R}$, $k \in \mathbb{N}$, $p \in (1, \infty)$. Then we will write:

- $L_\infty(J)$ for the set of functions essentially bounded and (Lebesgue) measurable on J; the corresponding norm is $\|u\|_\infty = \sup\operatorname{ess}\{|u(t)|\colon\ t \in J\}$.
- $L_1(J)$ for the set of functions (Lebesgue) integrable on J; the corresponding norm is $\|u\|_1 = \int_J |u(t)|\,\mathrm{d}t$.
- $L_p(J)$ for the set of functions whose pth powers of modulus are integrable on J; the corresponding norm is $\|u\|_p = (\int_J |u(t)|^p\,\mathrm{d}t)^{1/p}$.
- $C(J)$ and $C^k(J)$ for the sets of functions continuous on J and having continuous kth derivatives on J, respectively.
- $AC(J)$ and $AC^k(J)$ for the sets of functions absolutely continuous on J and having absolutely continuous kth derivatives on J, respectively.
- $AC_{loc}(J)$ and $AC^k_{loc}(J)$ for the sets of functions absolutely continuous on each compact interval $I \subset J$ and having absolutely continuous kth derivatives on each compact interval $I \subset J$, respectively.
- If $J = [a, b]$, we will simply write $C[a, b]$ instead of $C([a, b])$ and similarly for other types of intervals and other functional sets defined above.

Further, we use the following notation:

- If $u \in L_\infty[a, b]$ is continuous on $[a, b]$, then $\max\{|u(t)|\colon\ t \in [a, b]\} = \sup\operatorname{ess}\{|u(t)|\colon\ t \in [a, b]\}$. Therefore the norm in $C[a, b]$ will be denoted by $\|u\|_\infty = \max\{|u(t)|\colon\ t \in [a, b]\}$ and the norm in $C^k[a, b]$ by $\|u\|_{C^k} = \sum_{i=0}^k \|u^{(i)}\|_\infty$.
- Let $n \in \mathbb{N}$ and $\mathcal{M} \subset \mathbb{R}^n$. Then $\overline{\mathcal{M}}$ will denote the closure of $\mathcal{M}$, $\partial\mathcal{M}$ the boundary of $\mathcal{M}$ and meas $(\mathcal{M})$ the Lebesgue measure of $\mathcal{M}$.
- $\deg(\mathcal{I} - \mathcal{F}, \Omega)$ stands for the Leray–Schauder degree of $\mathcal{I} - \mathcal{F}$ with respect to Ω, where $\mathcal{I}$ denotes the identity operator.

We say that a function f satisfies *the Carathéodory conditions* on the set $[a, b] \times \mathcal{M}$ if:

$$f(\cdot, x_0, \dots, x_{n-1})\colon [a, b] \to \mathbb{R} \text{ is measurable}$$
$$\text{for all } (x_0, x_1, \dots, x_{n-1}) \in \mathcal{M}; \tag{0.1}$$

$$f(t, \cdot, \dots, \cdot)\colon \mathcal{M} \to \mathbb{R} \text{ is continuous for a.e. } t \in [a, b]; \tag{0.2}$$

$$\left\{\begin{array}{l} \text{for each compact set } \mathcal{K} \subset \mathcal{M} \text{ there is a function } m_{\mathcal{K}} \in L_1[a, b] \text{ such that} \\ \quad \left|f(t, x_0, \dots, x_{n-1})\right| \leqslant m_{\mathcal{K}}(t) \quad \text{for a.e. } t \in [a, b] \\ \text{and all } (x_0, x_1, \dots, x_{n-1}) \in \mathcal{K}. \end{array}\right. \tag{0.3}$$

In this case we will write $f \in Car([a, b] \times \mathcal{M})$. If $J \subset [a, b]$ and $J \neq \overline{J}$, then $f \in Car(J \times \mathcal{M})$ will mean that $f \in Car(I \times \mathcal{M})$ for each compact interval $I \subset J$.

1. Principles of solvability of singular higher order BVPs

1.1. *Regular and singular BVPs*

For $n \in \mathbb{N}$, $[0,T] \subset \mathbb{R}$, $i \in \{0,1,\dots,n-1\}$ and a closed set $\mathcal{B} \subset C^i[0,T]$ consider the boundary value problem

$$u^{(n)} = f\big(t, u, \dots, u^{(n-1)}\big), \tag{1.1}$$

$$u \in \mathcal{B}. \tag{1.2}$$

In what follows, we will investigate the solvability of problem (1.1), (1.2) on the set $[0,T] \times \mathcal{A}$, where $\mathcal{A}$ is a closed subset of $\mathbb{R}^n$ or $\mathcal{A} = \mathbb{R}^n$. The classical existence results are based on the assumption $f \in Car([0,T] \times \mathcal{A})$. In this case we will say that problem (1.1), (1.2) is *regular on* $[0,T] \times \mathcal{A}$. If $f \notin Car([0,T] \times \mathcal{A})$ we will say that problem (1.1), (1.2) is *singular on* $[0,T] \times \mathcal{A}$.

Motivated by the following applications we will mainly address singular problems.

EXAMPLE 1. In certain problems in fluid dynamics and boundary layer theory (see, e.g., Callegari, Friedman and Nachman [43–45]) the second order differential equation

$$u'' + \frac{\psi(t)}{u^{\lambda}} = 0 \tag{1.3}$$

arose. Here $\lambda \in (0,\infty)$ and $\psi \in C(0,1)$, $\psi \notin L_1[0,1]$. Equation (1.3) is known as the generalized Emden–Fowler equation. Its solvability with the Dirichlet boundary conditions

$$u(0) = u(1) = 0 \tag{1.4}$$

was investigated by Taliaferro [141] in 1979 and then by many other authors. Problem (1.3), (1.4) has been studied on the set $[0,1] \times [0,\infty)$ because positive solutions have been sought. We can see that $f(t,x) = \psi(t)x^{-\lambda}$ does not fulfill conditions (0.2) and (0.3) with $[a,b] = [0,1]$ and $\mathcal{M} = [0,\infty)$. Hence problem (1.3), (1.4) is singular on $[0,1] \times [0,\infty)$.

EXAMPLE 2. Consider the fourth order degenerate parabolic equation

$$U_t + \big(|U|^{\mu} U_{yyy}\big)_y = 0,$$

which arises in droplets and thin viscous flows models (see, e.g., [32,33]). The source-type solutions of this equation have the form

$$U(y,t) = t^{-b} u\big(yt^{-b}\big), \quad b = \frac{1}{\mu + 4},$$

which leads to the study of the third order ordinary differential equation on $[-1,1]$,

$$u''' = btu^{1-\mu}.$$

We see that $f(t,x) = btx^{1-\mu}$ is singular on $[-1,1] \times [0,\infty)$ if $\mu > 1$.

EXAMPLE 3. Similarly to Example 2, the sixth order degenerate equation

$$U_t - \left(|U|^{\mu} U_{yyyyy}\right)_y = 0$$

which arises in semiconductor models (Bernis [30,31]) leads to the fifth order ordinary differential equation

$$-u^{(5)} = \frac{t}{u^{\lambda}}$$

which is singular for $\lambda > 0$.

A solvability decision for singular boundary value problems requires an exact definition of a solution to such problems. Here, we will work with the same definition of a solution both for regular problems and for singular ones.

DEFINITION 1.1. A function $u \in AC^{n-1}[0,T] \cap \mathcal{B}$ is said to be a *solution of problem* (1.1), (1.2), if it satisfies the equality $u^{(n)}(t) = f(t, u(t), \dots, u^{(n-1)}(t))$ a.e. on $[0,T]$. If we investigate problem (1.1), (1.2) on $\mathcal{A} \neq \mathbb{R}^n$, we moreover require $(u(t), \dots, u^{(n-1)}(t)) \in \mathcal{A}$ for $t \in [0,T]$.

In literature, *an alternative approach to solvability* of singular problems can be found. In this approach, solutions are defined as functions whose $(n-1)$st derivatives can have discontinuities at some points in $[0,T]$. Here we will call them the w-solutions. According to Kiguradze [92] or Agarwal and O'Regan [3] we define them as follows. In contrast to our starting setting, to define w-solutions we assume that $i \in \{0, 1, \dots, n-2\}$ and $\mathcal{B}$ is a closed subset in $C^i[0,T]$.

DEFINITION 1.2. We say that u is *a w-solution of problem* (1.1), (1.2) if there exists a finite number of points $t_\nu \in [0,T]$, $\nu = 1, 2, \dots, r$, such that if we denote $J = [0,T] \setminus \{t_\nu\}_{\nu=1}^{r}$, then $u \in C^{n-2}[0,T] \cap AC_{loc}^{n-1}(J) \cap \mathcal{B}$ satisfies $u^{(n)}(t) = f(t, u(t), \dots, u^{(n-1)}(t))$ a.e. on $[0,T]$. If $\mathcal{A} \neq \mathbb{R}^n$ we require $(u(t), \dots, u^{(n-1)}(t)) \in \mathcal{A}$ for $t \in J$.

Clearly each solution is a w-solution and each w-solution which belongs to $AC^{n-1}[0,T]$ is a solution.

In the study of singular problem (1.1), (1.2) we will focus our attention on two types of singularities of the function f:

Let $J \subset [0,T]$. We say that $f : J \times \mathcal{A} \to \mathbb{R}$ has singularities in its *time variable* t, if $J \neq \overline{J} = [0,T]$ and

$$f \in Car(J \times \mathcal{A}) \quad \text{and} \quad f \notin Car\big([0,T] \times \mathcal{A}\big). \tag{1.5}$$

Let $\mathcal{D} \subset \mathcal{A}$. We say that $f : [0,T] \times \mathcal{D} \to \mathbb{R}$ has singularities in its *space variables* $x_0, x_1, \dots, x_{n-1}$, if $\mathcal{D} \neq \overline{\mathcal{D}} = \mathcal{A}$ and

$$f \in Car\big([0,T] \times \mathcal{D}\big) \quad \text{and} \quad f \notin Car\big([0,T] \times \mathcal{A}\big). \tag{1.6}$$

We will study particular cases of (1.5) and (1.6) which will be described in Section 1.2 and Section 1.3, respectively.

1.2. *Singularities in time variable*

According to (0.3) and (1.5) a function f has a singularity in its *time variable* t, if f is not integrable on $[0,T]$. Let us define it more precisely. Let $k \in \mathbb{N}$, $t_i \in [0,T]$, $i = 1, \dots, k$, $J = [0,T] \setminus \{t_1, t_2, \dots, t_k\}$ and let $f \in Car(J \times \mathcal{A})$. Assume that for each $i \in \{1, \dots, k\}$ there exists $(x_0, \dots, x_{n-1}) \in \mathcal{A}$ such that

$$\int_{t_i}^{t_i+\varepsilon} \big|f(t, x_0, \dots, x_{n-1})\big| \, \mathrm{d}t = \infty \quad \text{or} \quad \int_{t_i-\varepsilon}^{t_i} \big|f(t, x_0, \dots, x_{n-1})\big| \, \mathrm{d}t = \infty \tag{1.7}$$

for any sufficiently small $\varepsilon > 0$. Then f does not fulfill (0.3) with $\mathcal{M} = \mathcal{A}$ and, according to (1.5), function f has singularities in its time variable t, namely at the values $t_1, \dots, t_k$. We will call these values the *singular points* of f.

EXAMPLE. Let $f_i : \mathbb{R}^n \to \mathbb{R}$, $i = 1, 2, \dots, k$, be continuous. Then the function

$$f(t, x_0, \dots, x_{n-1}) = \sum_{i=1}^{k} \frac{1}{t - t_i} f_i(x_0, \dots, x_{n-1}),$$

has singular points $t_1, t_2, \dots, t_k$.

1.3. *Singularities in space variables*

By virtue of (0.2) and (1.6) we see that if f has a singularity in some of its *space variables* then f is not continuous in this variable on a region where f is studied. Motivated by Eq. (1.3) we will consider the following case. Let $\mathcal{A}_i \subset \mathbb{R}$ be a closed interval and let $c_i \in \mathcal{A}_i$, $\mathcal{D}_i = \mathcal{A}_i \setminus \{c_i\}$, $i = 0, 1, \dots, n-1$. Assume that there exists $j \in \{0, 1, \dots, n-1\}$ such that

$$\begin{cases} \limsup\limits_{x_j \to c_j, x_j \in \mathcal{D}_j} \big|f(t, x_0, \dots, x_j, \dots, x_{n-1})\big| = \infty \\ \text{for a.e. } t \in [0,T] \text{ and for some } x_i \in \mathcal{D}_i, \ i = 0, 1, \dots, n-1, \ i \neq j. \end{cases} \tag{1.8}$$

If we put $\mathcal{A} = \mathcal{A}_0 \times \cdots \times \mathcal{A}_{n-1}$, we see that f does not fulfill (0.2) with $\mathcal{M} = \mathcal{A}$ and, according to (1.6), the function f has a singularity in its space variable x_j, namely at the value c_j.

Let u be a solution of (1.1), (1.2) and let a point $t_u \in [0, T]$ be such that $u^{(j)}(t_u) = c_j$ for some $j \in \{0, \dots, n-1\}$. Then t_u is called *a singular point corresponding to the solution u*.

Now, let u be a w-solution of (1.1), (1.2). Assume that a point $t_u \in [0, T]$ is such that $u^{(n-1)}(t_u)$ does not exist or there is a $j \in \{0, \dots, n-1\}$ such that $u^{(j)}(t_u) = c_j$. Then t_u is called *a singular point corresponding to the w-solution u*.

EXAMPLE. Let $h_1, h_2, h_3 \in L_1[0, T]$, $h_2 \neq 0$, $h_3 \neq 0$ a.e. on $[0, T]$. Consider the Dirichlet problem

$$u'' + h_1(t) + \frac{h_2(t)}{u} + \frac{h_3(t)}{u'} = 0, \quad u(0) = u(T) = 0. \tag{1.9}$$

Let u be a solution of (1.9). Then 0 and T are singular points corresponding to u. Moreover, there exists at least one point $t_u \in (0, T)$ satisfying $u'(t_u) = 0$, which means that t_u is also a singular point corresponding to u. Note that (in contrast to the points 0 and T) we do not know the location of t_u in $(0, T)$.

In accordance with this example, we will distinguish two types of singular points corresponding to solutions or to w-solutions: *singular points of type I*, where we know their location in $[0, T]$ and *singular points of type II* whose location is not known.

1.4. *Existence principles for BVPs with time singularities*

Singular problems are usually investigated by means of auxiliary regular problems. To establish the existence of a solution of a singular problem we introduce a sequence of approximating regular problems which are solvable. Then we pass to the limit for the sequence of approximate solutions to get a solution of the original singular problem. Here we provide existence principles which contain the main rules for a construction of such sequences to get either w-solutions or solutions.

Consider problem (1.1), (1.2) on $[0, T] \times \mathcal{A}$. For the sake of simplicity assume that f has only one time singularity at $t = t_0$, $t_0 \in [0, T]$. It means that

$$\left\{\begin{array}{l} J = [0, T] \setminus \{t_0\},\ f \in Car(J \times \mathcal{A}) \text{ satisfies at least one of the conditions} \\ \text{(i)} \quad \displaystyle\int_{t_0-\varepsilon}^{t_0} \left| f(t, x_0, \dots, x_{n-1}) \right| \mathrm{d}t = \infty, \quad t_0 \in (0, T], \\ \text{(ii)} \quad \displaystyle\int_{t_0}^{t_0+\varepsilon} \left| f(t, x_0, \dots, x_{n-1}) \right| \mathrm{d}t = \infty, \quad t_0 \in [0, T), \\ \text{for some } (x_0, x_1, \dots, x_{n-1}) \in \mathcal{A} \text{ and each sufficiently small } \varepsilon > 0. \end{array}\right. \tag{1.10}$$

Let us have a sequence of regular problems

$$u^{(n)} = f_k\big(t, u, \ldots, u^{(n-1)}\big), \quad u \in \mathcal{B}, \tag{1.11}$$

where $f_k \in Car([0,T] \times \mathbb{R}^n)$, $k \in \mathbb{N}$.

THEOREM 1.3 (First existence principle for w-solutions of (1.1), (1.2)). *Let* (1.10) *hold and let $\mathcal{B}$ be a closed subset in $C^{n-2}[0,T]$. Assume that the conditions*

$$\begin{cases} \textit{for each } k \in \mathbb{N} \textit{ and each } (x_0, \ldots, x_{n-1}) \in \mathcal{A}, \\ f_k(t, x_0, \ldots, x_{n-1}) = f(t, x_0, \ldots, x_{n-1}) \quad \textit{a.e. on } [0,T] \setminus \Delta_k, \\ \textit{where } \Delta_k = \big(t_0 - \frac{1}{k}, t_0 + \frac{1}{k}\big) \cap [0,T], \end{cases} \tag{1.12}$$

and

$$\begin{cases} \textit{there exists a bounded set } \Omega \subset C^{n-1}[0,T] \textit{ such that} \\ \textit{for each } k \in \mathbb{N} \textit{ the regular problem } (1.11) \textit{ has a solution } u_k \in \Omega \\ \textit{and } \big(u_k(t), \ldots, u_k^{(n-1)}(t)\big) \in \mathcal{A} \textit{ for } t \in [0,T] \end{cases} \tag{1.13}$$

are fulfilled. Then

$$\begin{cases} \textit{there exist a function } u \in C^{n-2}[0,T] \textit{ and a subsequence} \\ \{u_{k_\ell}\} \subset \{u_k\} \textit{ such that } \lim_{\ell \to \infty} \|u_{k_\ell} - u\|_{C^{n-2}} = 0; \end{cases} \tag{1.14}$$

$$\begin{cases} \lim_{\ell \to \infty} u_{k_\ell}^{(n-1)}(t) = u^{(n-1)}(t) \textit{ locally uniformly on } J \\ \textit{and } \big(u(t), \ldots, u^{(n-1)}(t)\big) \in \mathcal{A} \textit{ for } t \in J; \end{cases} \tag{1.15}$$

$$\textit{the function } u \in AC_{loc}^{n-1}(J) \textit{ is a w-solution of problem } (1.1), (1.2). \tag{1.16}$$

SKETCH OF THE PROOF. *Step* 1. *Convergence of the sequence of approximate solutions.*

Condition (1.13) implies that the sequences $\{u_k^{(i)}\}$, $0 \leqslant i \leqslant n-2$, are bounded and equicontinuous on $[0,T]$. By the Arzelà–Ascoli theorem the assertion (1.14) is true and $u \in \mathcal{B} \subset C^{n-2}[0,T]$. Since $\{u_k^{(n-1)}\}$ is bounded on $[0,T]$, we get, due to (1.11) and (1.12), that for each $t \in [0, t_0)$ the sequence $\{u_k^{(n-1)}\}$ is equicontinuous on $[0,t]$ and so the same holds on $[t,T]$ if $t \in (t_0, T]$. The Arzelà–Ascoli theorem and the diagonalization principle yield (1.15).

Step 2. *Properties of the limit u.*

By virtue of (1.12), (1.14) and (1.15) we have

$$\lim_{k_\ell \to \infty} f_{k_\ell}\big(t, u_{k_\ell}(t), \ldots, u_{k_\ell}^{(n-1)}(t)\big) = f\big(t, u(t), \ldots, u^{(n-1)}(t)\big)$$

$$\text{a.e. on } [0,T]. \tag{1.17}$$

Hence, using the Lebesgue convergence theorem, we can deduce that if $t_0 \neq 0$ the limit u solves the equation

$$u^{(n-1)}(t) = u^{(n-1)}(0) + \int_0^t f\bigl(s, u(s), \dots, u^{(n-1)}(s)\bigr)\,\mathrm{d}s \quad \text{for } t \in [0, t_0) \tag{1.18}$$

and if $t_0 \neq T$ the limit u solves the equation

$$u^{(n-1)}(t) = u^{(n-1)}(T) - \int_t^T f\bigl(s, u(s), \dots, u^{(n-1)}(s)\bigr)\,\mathrm{d}s \quad \text{for } t \in (t_0, T], \tag{1.19}$$

which immediately yields (1.16). □

For the existence of a solution $u \in AC^{n-1}[0, T]$ of problem (1.1), (1.2) we will impose additional conditions on f on some neighbourhood of t_0.

THEOREM 1.4 (First existence principle for solutions of (1.1), (1.2)). *Let all assumptions of Theorem* 1.3 *be fulfilled. Further, assume that*

$$\begin{cases} \textit{there exist } \psi \in L_1[0,T],\ \eta > 0 \textit{ and } \lambda_1, \lambda_2 \in \{-1, 1\} \textit{ such that} \\ \quad \lambda_1 f_{k_\ell}\bigl(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\bigr) \geqslant \psi(t) \\ \textit{for all } \ell \in \mathbb{N} \textit{ and for a.e. } t \in [t_0 - \eta, t_0) \cap [0, T] \textit{ provided } (1.10)(\mathrm{i}) \textit{ holds}, \\ \quad \lambda_2 f_{k_\ell}\bigl(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\bigr) \geqslant \psi(t) \\ \textit{for all } \ell \in \mathbb{N} \textit{ and for a.e. } t \in (t_0, t_0 + \eta] \cap [0, T] \textit{ provided } (1.10)(\mathrm{ii}) \textit{ is true}. \end{cases} \tag{1.20}$$

Then the assertions (1.14) *and* (1.15) *are valid and* $u \in AC^{n-1}[0, T]$ *is a solution of problem* (1.1), (1.2).

SKETCH OF THE PROOF. *Step* 1. As in the proof of Theorem 1.3 we get that (1.14)–(1.16) hold.

Step 2. Since u is a w-solution of problem (1.1), (1.2), it remains to prove that $u \in AC^{n-1}[0, T]$. Assume that condition (1.10)(i) holds. Since

$$u_{k_\ell}^{(n-1)}(t) - u_{k_\ell}^{(n-1)}(t_0 - \eta) = \int_{t_0-\eta}^t f_{k_\ell}\bigl(s, u_{k_\ell}(s), \dots, u_{k_\ell}^{(n-1)}(s)\bigr)\,\mathrm{d}s \tag{1.21}$$

for $t \in (0, t_0)$, we get due to (1.13) that there is a $c \in (0, \infty)$ such that

$$\lambda_1 \int_{t_0-\eta}^{t_0} f_{k_\ell}\big(s, u_{k_\ell}(s), \ldots, u_{k_\ell}^{(n-1)}(s)\big)\,\mathrm{d}s \leqslant c \tag{1.22}$$

for each $\ell \in \mathbb{N}$. By the Fatou lemma, having in mind conditions (1.17), (1.20) and (1.22), we deduce that $f(t, u(t), \ldots, u^{(n-1)}(t)) \in L_1[0, t_0]$. Similarly, if condition (1.10)(ii) holds, we deduce that $f(t, u(t), \ldots, u^{(n-1)}(t)) \in L_1[t_0, T]$. Therefore $f(t, u(t), \ldots, u^{(n-1)}(t)) \in L_1[0, T]$ and due to (1.18) and (1.19) we have that $u \in AC^{n-1}[0, T]$ is a solution of problem (1.1), (1.2). □

In the sequel we will need the following definition:

DEFINITION 1.5. Let $[a, b] \subset \mathbb{R}$ and $\{g_k\} \subset L_1[a, b]$. We say that the sequence $\{g_k\}$ is *uniformly integrable on* $[a, b]$ if

$$\begin{cases} \text{for each } \varepsilon > 0 \text{ there exists } \delta > 0 \text{ such that} \\ \displaystyle\sum_{j=1}^{\infty}(b_j - a_j) < \delta \quad \Longrightarrow \quad \sum_{j=1}^{\infty}\int_{a_j}^{b_j} \big|g_k(t)\big|\,\mathrm{d}t < \varepsilon \\ \text{for each } k \in \mathbb{N} \text{ and each sequence of intervals } \{(a_j, b_j)\} \text{ in } [a, b]. \end{cases} \tag{1.23}$$

Note that condition (1.23) is satisfied for example if there exists $\psi \in L_1[a, b]$ such that $|g_k(t)| \leqslant \psi(t)$ for a.e. $t \in [a, b]$ and all $k \in \mathbb{N}$.

THEOREM 1.6 (Second existence principle for solutions of (1.1), (1.2)). *Let all assumptions of Theorem* 1.3 *be fulfilled and assume in addition that $\mathcal{B}$ is a closed subset in $C^{n-1}[0, T]$ and that*

$$\begin{cases} \textit{there exists } \eta > 0 \textit{ such that the sequence } \big\{f_k\big(t, u_k(t), \ldots, u_k^{(n-1)}(t)\big)\big\} \\ \textit{is uniformly integrable on } [t_0 - \eta, t_0 + \eta] \cap [0, T]. \end{cases} \tag{1.24}$$

Then

$$\begin{cases} \textit{there exist a function } u \in \overline{\Omega} \textit{ and a subsequence } \{u_{k_\ell}\} \subset \{u_k\} \textit{ such that} \\ \quad \lim\limits_{\ell\to\infty} \|u_{k_\ell} - u\|_{C^{n-1}} = 0 \textit{ and } \big(u(t), \ldots, u^{(n-1)}(t)\big) \in \mathcal{A} \quad \textit{for } t \in [0, T] \end{cases} \tag{1.25}$$

and $u \in AC^{n-1}[0, T]$ is a solution of problem (1.1), (1.2).

SKETCH OF THE PROOF. *Step* 1. By (1.13) we get that the sequences $\{u_k^{(i)}\}$, $0 \leqslant i \leqslant n-2$, are bounded in $C[0,T]$ and equicontinuous on $[0,T]$ and $\{u_k^{(n-1)}\}$ is bounded in $C[0,T]$. Using (1.24) one can show that $\{u_k^{(n-1)}\}$ is also equicontinuous on $[0,T]$. The Arzelà–Ascoli theorem yields (1.25) and $u \in \mathcal{B} \subset C^{n-1}[0,T]$.

Step 2. As in Step 2 of the proof of Theorem 1.3 we get that u is a w-solution of problem (1.1), (1.2).

Step 3. It remains to prove that $u \in AC^{n-1}[0,T]$. Since $u \in AC_{loc}^{n-1}(J)$, it is sufficient to prove

$$u^{(n-1)} \in AC\big([t_0-\eta, t_0+\eta] \cap [0,T]\big). \tag{1.26}$$

Assume that (1.10)(i) holds and $[t_0-\eta, t_0] \subset [0,T]$. By virtue of (1.17) and (1.24), applying Vitali's convergence theorem we obtain $f(t, u(t), \dots, u^{(n-1)}(t)) \in L_1[t_0-\eta, t_0]$. If (1.10)(ii) holds, we can assume $[t_0, t_0+\eta] \subset [0,T]$ and deduce similarly that

$$f\big(t, u(t), \dots, u^{(n-1)}(t)\big) \in L_1[t_0, t_0+\eta].$$

Hence, we get (1.26). □

1.5. *Existence principles for BVPs with space singularities*

Similarly to Section 1.4 we will establish sufficient properties for an approximate sequence of regular problems and of their solutions to pass to a limit and yield a solution of the original singular problem (1.1), (1.2). Let $\mathcal{A}_i \subset \mathbb{R}$, $i = 0, \dots, n-1$, be closed intervals and let $\mathcal{A} = \mathcal{A}_0 \times \cdots \times \mathcal{A}_{n-1}$. Consider problem (1.1), (1.2) on $[0,T] \times \mathcal{A}$ and assume that f has only one singularity at each x_i, namely at the values $c_i \in \mathcal{A}_i$, $i = 0, \dots, n-1$. Denoting $\mathcal{D} = \mathcal{D}_0 \times \cdots \times \mathcal{D}_{n-1}$, $\mathcal{D}_i = \mathcal{A}_i \setminus \{c_i\}$, $i = 0, \dots, n-1$, we will assume that

$$f \in Car\big([0,T] \times \mathcal{D}\big) \text{ satisfies (1.8)} \quad \text{for } j = 0, \dots, n-1. \tag{1.27}$$

Consider a sequence of regular problems (1.11) where $f_k \in Car([0,T] \times \mathbb{R}^n)$, $k \in \mathbb{N}$. We will use the approach used by Rachůnková and Staněk in [121] and [122].

THEOREM 1.7 (Second existence principle for w-solutions of (1.1), (1.2)). *Let* (1.13), (1.27) *hold and let $\mathcal{B}$ be a closed subset in $C^{n-2}[0,T]$. Assume that*

$$\begin{cases} \text{for each } k \in \mathbb{N}, \text{ for a.e. } t \in [0,T] \text{ and each } (x_0, \dots, x_{n-1}) \in \mathcal{D} \\ \text{we have} \\ \quad f_k(t, x_0, \dots, x_{n-1}) = f(t, x_0, \dots, x_{n-1}) \\ \quad \text{if } |x_i - c_i| \geqslant \frac{1}{k},\ 0 \leqslant i \leqslant n-1. \end{cases} \tag{1.28}$$

Then the assertion (1.14) *is valid.*

If, moreover, the set

$$\Sigma = \big\{ s \in [0,T] \colon u^{(i)}(s) = c_i \text{ for some } i \in \{0, \dots, n-1\}$$
$$\text{or } u^{(n-1)}(s) \text{ does not exist} \big\}$$

is finite, then the assertion (1.15) *is valid for* $J = [0,T] \setminus \Sigma$. *If, in addition,*

$$\begin{cases} \text{the sequence } \left\{ f_{k_\ell}\big(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\big)\right\} \\ \text{is uniformly integrable on each interval } [a,b] \subset J \end{cases} \tag{1.29}$$

then $u \in AC_{loc}^{n-1}(J)$ *is a w-solution of problem* (1.1), (1.2).

SKETCH OF THE PROOF. *Step* 1. *Convergence of the sequence of approximate solutions.*

As in Step 1 of the proof of Theorem 1.3 we get (1.14) and $u \in \mathcal{B} \subset C^{n-2}[0,T]$. Assume that Σ is finite and choose an arbitrary $[a,b] \subset J$. According to (1.27) and (1.28) we can prove that the sequence $\{u_{k_\ell}^{(n-1)}\}$ is equicontinuous on $[a,b]$. Using the Arzelà–Ascoli theorem and the diagonalization principle we deduce that the subsequence $\{u_{k_\ell}\}$ can be chosen so that it fulfills (1.15).

Step 2. *Convergence of the sequence of regular right-hand sides.*

Consider sets

$$\mathcal{V}_1 = \big\{t \in [0,T]\colon\ f(t,\cdot,\dots,\cdot)\colon \mathcal{D} \to \mathbb{R} \text{ is not continuous}\big\},$$
$$\mathcal{V}_2 = \big\{t \in [0,T]\colon\ \text{the equality in (1.28) is not valid}\big\}.$$

We can see that $\operatorname{meas}(\mathcal{V}_1) = \operatorname{meas}(\mathcal{V}_2) = 0$. Denote $\mathcal{U} = \Sigma \cup \mathcal{V}_1 \cup \mathcal{V}_2$ and choose an arbitrary $t \in [0,T] \setminus \mathcal{U}$. By (1.14) and (1.15) there exists $\ell_0 \in \mathbb{N}$ such that for each $\ell \in \mathbb{N}$, $\ell \geqslant \ell_0$,

$$\big|u^{(i)}(t) - c_i\big| > \frac{1}{k_\ell}, \quad \big|u_{k_\ell}^{(i)}(t) - c_i\big| \geqslant \frac{1}{k_\ell} \quad \text{for } i \in \{0,\dots,n-1\}.$$

According to (1.28) we have

$$f_{k_\ell}\big(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\big) = f\big(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\big)$$

and, by (1.14), (1.15),

$$\lim_{\ell\to\infty} f_{k_\ell}\big(t, u_{k_\ell}(t), \dots, u_{k_\ell}^{(n-1)}(t)\big) = f\big(t, u(t), \dots, u^{(n-1)}(t)\big). \tag{1.30}$$

Since $\operatorname{meas}(\mathcal{U}) = 0$, (1.30) holds for a.e. $t \in [0,T]$.

Step 3. *Existence of a w-solution.*

Choose an arbitrary interval $[a,b] \subset J$. By (1.29) and (1.30) we can use Vitali's convergence theorem [23] to show that $f(t, u(t), \dots, u^{(n-1)}(t)) \in L_1[a,b]$ and if we pass to the limit in the sequence

$$u_{k_\ell}^{(n-1)}(t) = u_{k_\ell}^{(n-1)}(a) + \int_a^t f_{k_\ell}\big(s, u_{k_\ell}(s), \dots, u_{k_\ell}^{(n-1)}(s)\big)\,\mathrm{d}s, \quad t \in [a,b],$$

we get

$$u^{(n-1)}(t) = u^{(n-1)}(a) + \int_a^t f\big(s, u(s), \ldots, u^{(n-1)}(s)\big)\,\mathrm{d}s, \quad t \in [a, b].$$

Since $[a, b] \subset J$ is an arbitrary interval, we conclude that $u \in AC_{loc}^{n-1}(J)$ satisfies Eq. (1.1) for a.e. $t \in [0, T]$. □

THEOREM 1.8 (Third existence principle for solutions of (1.1), (1.2)). *Let* (1.13), (1.27), (1.28) *hold and let* $\mathcal{B}$ *be a closed subset of* $C^{n-1}[0, T]$. *Further, assume that the sequence*

$$\big\{f_k\big(t, u_k(t), \ldots, u_k^{(n-1)}(t)\big)\big\} \quad \textit{is uniformly integrable on } [0, T]. \tag{1.31}$$

Then the assertion (1.25) *is valid. If, moreover, the functions* $u^{(i)} - c_i$, $0 \leqslant i \leqslant n-1$, *have at most a finite number of zeros in* $[0, T]$, *then* $u \in AC^{n-1}[0, T]$ *is a solution of* (1.1), (1.2).

SKETCH OF THE PROOF. *Step* 1. As in Step 1 in the proof of Theorem 1.6 we get that (1.25) is valid and $u \in \mathcal{B} \subset C^{n-1}[0, T]$.

Step 2. As in Step 2 in the proof of Theorem 1.7 we get that (1.30) is valid.

Step 3. We can argue as in Step 3 in the proof of Theorem 1.7 if we take $[0, T]$ instead of $[a, b]$ and (1.31) instead of (1.29). □

2. Existence results for singular two-point higher order BVPs

In this section we are interested in problems for higher order differential equations having singularities in their space variables only (see Section 1.3). We consider the focal, conjugate, (n, p), Sturm–Liouville and Lidstone boundary conditions which appear most frequently in literature. Boundary conditions considered are two-point, linear and homogeneous.

Existence results for the above singular problems are proved by regularization and sequential techniques which consist in the construction of a proper sequence of auxiliary regular problems and in limit processes (see Section 1.5). To prove solvability of the auxiliary regular problems we use the Nonlinear Fredholm Alternative (see, e.g., [95, Theorem 4] or [146, p. 25]) which we formulate in the form convenient for our problems. In particular, we consider the differential equation

$$u^{(n)} + \sum_{i=0}^{n-1} a_i(t)u^{(i)} = g\big(t, u, \ldots, u^{(n-1)}\big) \tag{2.1}$$

and the corresponding linear homogeneous differential equation

$$u^{(n)} + \sum_{i=0}^{n-1} a_i(t)u^{(i)} = 0 \tag{2.2}$$

where $a_i \in L_1[0,T]$, $0 \leqslant i \leqslant n-1$, $g \in Car([0,T] \times \mathbb{R}^n)$. Further, we introduce boundary conditions

$$\mathcal{L}_j(u) = r_j, \quad 1 \leqslant j \leqslant n, \tag{2.3}$$

and the corresponding homogeneous boundary conditions

$$\mathcal{L}_j(u) = 0, \quad 1 \leqslant j \leqslant n, \tag{2.4}$$

where $\mathcal{L}_j : C^{n-1}[0,T] \to \mathbb{R}$ are linear and continuous functionals and $r_j \in \mathbb{R}$, $1 \leqslant j \leqslant n$.

THEOREM 2.1 (Nonlinear Fredholm Alternative). *Let the linear homogeneous problem* (2.2), (2.4) *have only the trivial solution and let there exist a function* $\psi \in L_1[0,T]$ *such that*

$$\left|g(t, x_0, \ldots, x_{n-1})\right| \leqslant \psi(t) \quad \textit{for a.e. } t \in [0,T] \textit{ and all } x_0, \ldots, x_{n-1} \in \mathbb{R}.$$

Then the nonlinear problem (2.1), (2.3) *has a solution* $u \in AC^{n-1}[0,T]$.

2.1. *Focal conditions*

We discuss the singular $(p, n-p)$ right focal problem

$$(-1)^{n-p} u^{(n)} = f\big(t, u, \ldots, u^{(n-1)}\big), \tag{2.5}$$

$$u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant p-1, \qquad u^{(j)}(T) = 0, \ p \leqslant j \leqslant n-1, \tag{2.6}$$

where $n \geqslant 2$, $p \in \mathbb{N}$ is fixed, $1 \leqslant p \leqslant n-1$, $f \in Car([0,T] \times \mathcal{D})$ with

$$\mathcal{D} = \begin{cases} \underbrace{\mathbb{R}_+^{p+1} \times \mathbb{R}_- \times \mathbb{R}_+ \times \mathbb{R}_- \times \cdots \times \mathbb{R}_+}_{n} & \text{if } n-p \text{ is odd,} \\ \underbrace{\mathbb{R}_+^{p+1} \times \mathbb{R}_- \times \mathbb{R}_+ \times \mathbb{R}_- \times \cdots \times \mathbb{R}_-}_{n} & \text{if } n-p \text{ is even} \end{cases}$$

and f may be singular at the value 0 of all its space variables. Here $\mathbb{R}_- = (-\infty, 0)$ and $\mathbb{R}_+ = (0, \infty)$. Notice that if $f > 0$ then the singular points corresponding to the solutions of problem (2.5), (2.6) are only of type I. The Green function of problem $u^{(n)} = 0$, (2.6) is presented in [18] and [19].

The existence result for the singular problem (2.5), (2.6) is given in the following theorem.

THEOREM 2.2 [120, Theorem 4.3]. *Let* $f \in Car([0,T] \times \mathcal{D})$ *and let there exist positive constants* ε *and* r *such that*

$$\varepsilon (T-t)^r \leqslant f(t, x_0, \ldots, x_{n-1})$$

for a.e. $t \in [0, T]$ *and each* $(x_0, \ldots, x_{n-1}) \in \mathcal{D}$.

Also assume that for a.e. $t \in [0, T]$ *and each* $(x_0, \ldots, x_{n-1}) \in \mathcal{D}$ *we have*

$$f(t, x_0, \ldots, x_{n-1}) \leqslant \varphi(t) + \sum_{i=0}^{n-1} \omega_i\bigl(|x_i|\bigr) + \sum_{i=0}^{n-1} h_i(t)|x_i|^{\alpha_i},$$

where $\alpha_i \in (0, 1)$, $\varphi, h_i \in L_1[0, T]$ *are nonnegative*, $\omega_i : \mathbb{R}_+ \to \mathbb{R}_+$ *are nonincreasing*, $0 \leqslant i \leqslant n-1$, *and*

$$\int_0^T \omega_i\bigl(t^{r+n-i}\bigr)\,\mathrm{d}t < \infty \quad \textit{for } 0 \leqslant i \leqslant n-1.$$

Then there exists a solution $u \in AC^{n-1}[0, T]$ *of problem* (2.5), (2.6) *with*

$$\begin{cases} u^{(i)} > 0 \quad \textit{on } (0, T] & \textit{for } 0 \leqslant i \leqslant p-1, \\ (-1)^{j-p} u^{(j)} > 0 \quad \textit{on } [0, T) & \textit{for } p \leqslant j \leqslant n-1. \end{cases} \tag{2.7}$$

SKETCH OF PROOF. *Step* 1. *Construction of a sequence of regular differential equations related to Eq.* (2.5).

Put

$$\varphi^*(t) = \varphi(t) + \sum_{i=0}^{n-1} \omega_i(1) + \sum_{i=0}^{n-1} h_i(t) \quad \text{for a.e. } t \in [0, T].$$

Then $\varphi^* \in L_1[0, T]$ and there exists $r^* > 0$ such that the estimate $\|u^{(n-1)}\|_\infty < r^*$ is valid for any function $u \in AC^{n-1}[0, T]$ satisfying (2.6), $(-1)^{n-p} u^{(n)}(t) \geqslant \varepsilon (T-t)^r$ and

$$(-1)^{n-p} u^{(n)}(t) \leqslant \varphi^*(t) + \sum_{i=0}^{n-1} \omega_i\bigl(\bigl|u^{(i)}(t)\bigr|\bigr) + \sum_{i=0}^{n-1} h_i(t)\bigl|u^{(i)}(t)\bigr|^{\alpha_i}$$

for a.e. $t \in [0, T]$. Now for $m \in \mathbb{N}$, $0 \leqslant i \leqslant n-1$ and $x \in \mathbb{R}$, put $\varrho_i = 1 + r^* T^{n-i-1}$ and

$$\sigma_i\bigl(\tfrac{1}{m}, x\bigr) = \begin{cases} \frac{1}{m} \operatorname{sign} x & \text{for } |x| < \frac{1}{m}, \\ x & \text{for } \frac{1}{m} \leqslant |x| \leqslant \varrho_i, \\ \varrho_i \operatorname{sign} x & \text{for } \varrho_i < |x|. \end{cases}$$

Extend f onto $[0, T] \times (\mathbb{R} \setminus \{0\})^n$ as an even function in each of its space variables x_i, $0 \leqslant i \leqslant n-1$, and for a.e. $t \in [0, T]$ and each $(x_0, \ldots, x_{n-1}) \in \mathbb{R}^n$, define auxiliary functions

$$f_m(t, x_0, \ldots, x_{n-1}) = f\left(t, \sigma_0\left(\frac{1}{m}, x_0\right), \ldots, \sigma_{n-1}\left(\frac{1}{m}, x_{n-1}\right)\right), \quad m \in \mathbb{N}.$$

In this way we get the family of regular differential equations

$$(-1)^{n-p}u^{(n)} = f_m\bigl(t, u, \ldots, u^{(n-1)}\bigr) \tag{2.8}$$

depending on $m \in \mathbb{N}$.

Step 2. *Properties of solutions to problems* (2.8), (2.6).

By Theorem 2.1 we show that for any $m \in \mathbb{N}$, problem (2.8), (2.6) has a solution $u_m \in AC^{n-1}[0,T]$ satisfying (for $t \in [0,T]$)

$$\begin{cases} u_m^{(i)}(t) \geqslant ct^{r+n-i} & \text{if } 0 \leqslant i \leqslant p-1, \\ (-1)^{i-p}u_m^{(i)}(t) \geqslant c(T-t)^{r+n-i} & \text{if } p \leqslant i \leqslant n-1, \end{cases} \tag{2.9}$$

where c is a positive constant and $\|u_m^{(n-1)}\|_\infty < r^*$. Moreover, the sequence $\{u_m^{(n-1)}\}$ is equicontinuous on $[0,T]$. By virtue of the Arzelà–Ascoli theorem, a convergent subsequence $\{u_{k_m}\}$ exists and let $\lim_{m\to\infty} u_{k_m} = u$. Then $u \in C^{n-1}[0,T]$, u satisfies (2.6) and, because of (2.9),

$$\begin{aligned} &u^{(i)}(t) \geqslant ct^{r+n-i} && \text{for } t \in [0,T] \text{ and } 1 \leqslant i \leqslant p-1, \\ &(-1)^{i-p}u^{(i)}(t) \geqslant c(T-t)^{r+n-i} && \text{for } t \in [0,T] \text{ and } p \leqslant i \leqslant n-1. \end{aligned}$$

Also,

$$\bigl|f_{k_m}\bigl(t, u_{k_m}(t), \ldots, u_{k_m}^{(n-1)}(t)\bigr)\bigr| \leqslant \varrho(t) \quad \text{for a.e. } t \in [0,T] \text{ and all } m \in \mathbb{N},$$

where $\varrho \in L_1[0,T]$ and

$$\lim_{m\to\infty} f_{k_m}\bigl(t, u_{k_m}(t), \ldots, u_{k_m}^{(n-1)}(t)\bigr) = f\bigl(t, u(t), \ldots, u^{(n-1)}(t)\bigr) \quad \text{for a.e. } t \in [0,T].$$

Now, letting $m \to \infty$ in

$$u_{k_m}^{(n-1)}(t) = u_{k_m}^{(n-1)}(0) + (-1)^{n-p}\int_0^t f_{k_m}\bigl(s, u_{k_m}(s), \ldots, u_{k_m}^{(n-1)}(s)\bigr)\,\mathrm{d}s$$

we conclude

$$u^{(n-1)}(t) = u^{(n-1)}(0) + (-1)^{n-p}\int_0^t f\bigl(s, u(s), \ldots, u^{(n-1)}(s)\bigr)\,\mathrm{d}s, \quad t \in [0,T].$$

Hence $u \in AC^{n-1}[0,T]$ and u is a solution of problem (2.5), (2.6). □

EXAMPLE. Let $\gamma \in (0,1)$, $\alpha_i \in [0,1)$, $c_i \in (0,\infty)$, $\beta_i \in (0, \frac{1}{n+\gamma-i})$ and let $h_i \in L_1[0,T]$ be nonnegative for $0 \leqslant i \leqslant n-1$. Then, by Theorem 2.2, there exists a solution $u \in AC^{n-1}[0,T]$ of the differential equation

$$(-1)^{n-p}u^{(n)} = \left(\frac{T-t}{t}\right)^{\gamma} + \sum_{i=0}^{n-1} \frac{c_i}{|u^{(i)}|^{\beta_i}} + \sum_{i=0}^{n-1} h_i(t)\bigl|u^{(i)}\bigr|^{\alpha_i}$$

satisfying the $(p, n-p)$ right focal boundary conditions (2.6) and (2.7).

REMARK 2.3. Substituting $t = T - s$ in (2.5), (2.6) and using Theorem 2.2 we can also give results for the existence of solutions to singular differential equations satisfying $(n-p, p)$ left focal boundary conditions

$$u^{(i)}(0) = 0, \quad p \leqslant i \leqslant n-1, \qquad u^{(j)}(T) = 0, \quad 0 \leqslant j \leqslant p-1$$

(see [120, Theorem 4.4]).

The singular problem (2.5), (2.6) was also considered on the interval [0, 1] by Agarwal, O'Regan and Lakshmikantham in [12] where f is assumed to be continuous and independent of space variables $x_p, \dots, x_{n-1}$ and may be singular at $x_i = 0$, $0 \leqslant i \leqslant p-1$. They examined the problem

$$\begin{cases} (-1)^{n-p}u^{(n)} = \varphi(t)h\bigl(t, u, \dots, u^{(p-1)}\bigr), \\ u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant p-1, \qquad u^{(j)}(1) = 0, \quad p \leqslant j \leqslant n-1, \end{cases} \tag{2.10}$$

under the assumptions

$$\varphi \in C^0(0,1) \quad \text{with } \varphi > 0 \text{ on } (0,1) \text{ and } \varphi \in L_1[0,1], \tag{2.11}$$

$$h : [0,1] \times \mathbb{R}_+^p \to \mathbb{R}_+ \text{ is continuous,} \tag{2.12}$$

$$\begin{cases} h(t, x_0, \dots, x_{p-1}) \leqslant \sum_{i=0}^{p-1} g_i(x_i) + r\bigl(\max\{x_0, \dots, x_{p-1}\}\bigr) \quad \text{on } [0,1] \times \mathbb{R}_+^p \\ \text{with } g_i > 0 \text{ continuous and nonincreasing on } \mathbb{R}_+ \text{ for each } i = 0, \dots, p-1 \\ \text{and } r \geqslant 0 \text{ continuous and nondecreasing on } [0,\infty), \end{cases} \tag{2.13}$$

$$\begin{cases} h(t, x_0, \dots, x_{p-1}) \geqslant \sum_{i=0}^{p-1} h_i(x_i) \quad \text{on } [0,1] \times \mathbb{R}_+^p \\ \text{with } h_i > 0 \text{ continuous and nonincreasing on } \mathbb{R}_+ \text{ for each } i = 0, \dots, p-1, \end{cases} \tag{2.14}$$

$$\begin{cases} \int_0^1 \varphi(t) g_i\big(k_i t^{p-i}\big)\,\mathrm{d}t < \infty \quad \text{for each } i = 0, \ldots, p-1, \\ \text{where } k_i > 0 \ (i = 0, \ldots, p-1) \text{ are constants} \end{cases} \tag{2.15}$$

and

$$\begin{cases} \text{if } z > 0 \text{ satisfies } z \leqslant a_0 + b_0 r(z) \text{ for constants } a_0 \geqslant 0 \text{ and } b_0 \geqslant 0, \\ \text{then there exists a constant } K \text{ (which may depend only on } a_0 \text{ and } b_0) \\ \text{such that } z \leqslant K. \end{cases} \tag{2.16}$$

The next result was proved by sequential technique and a nonlinear alternative of Leray–Schauder type [77, Theorem 2.3].

THEOREM 2.4 [12, Theorem 2.1]. *Suppose* (2.11)–(2.16) *hold. Then problem* (2.10) *has a solution* $u \in C^{n-1}[0,1] \cap C^n(0,1)$ *with* $u^{(i)} > 0$ *on* $(0,1]$ *for* $0 \leqslant i \leqslant p-1$.

EXAMPLE. Consider the problem

$$\begin{cases} (-1)^{n-p} u^{(n)} = \displaystyle\sum_{i=0}^{p-1} \left(\frac{1}{(u^{(i)})^{\beta_i}} + \mu_i \big(u^{(i)}\big)^{\alpha_i} + \tau_i \right), \\ u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant p-1, \qquad u^{(j)}(1) = 0, \quad p \leqslant j \leqslant n-1 \end{cases} \tag{2.17}$$

with $\beta_i \in (0,\infty)$, $\mu_i, \tau_i \in [0,\infty)$, $\alpha_i \in [0,1)$ for $0 \leqslant i \leqslant p-1$. In addition, assume $\beta_i(p-i) < 1$ for $i = 0, \ldots, p-1$. Theorem 2.4 guarantees that problem (2.17) has a solution $u \in C^{n-1}[0,1] \cap C^n(0,1)$ with $u^{(i)} > 0$ on $(0,1]$ for $0 \leqslant i \leqslant p-1$.

2.2. *Conjugate conditions*

Let $1 \leqslant p \leqslant n-1$ be a fixed natural number. Consider the $(p, n-p)$ conjugate problem

$$(-1)^p u^{(n)} = f\big(t, u, \ldots, u^{(n-1)}\big), \tag{2.18}$$

$$u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant n-p-1, \qquad u^{(j)}(T) = 0, \quad 0 \leqslant j \leqslant p-1 \tag{2.19}$$

where $n \geqslant 2$, $f \in Car([0,T] \times \mathcal{D})$, $\mathcal{D} = (0,\infty) \times (\mathbb{R} \setminus \{0\})^{n-1}$ and f may be singular at the value 0 of all its space variables.

Replacing t by $T - t$, if necessary, we may assume that $p \in \{1, \ldots, \frac{n}{2}\}$ for n even and $p \in \{1, \ldots, \frac{n+1}{2}\}$ for n odd. We observe that the larger p is chosen, the more complicated structure of the set of all singular points of a solution to (2.18), (2.19) and its derivatives is obtained. We note that solutions of problem (2.18), (2.19) have singular points of type I at $t = 0$ and/or $t = T$ and also singular points of type II. Since the singular problem (2.18), (2.19) for $n = 2$ is the Dirichlet problem discussed in Section 4, we assume that $n > 2$.

THEOREM 2.5 ([121, Theorems 2.1 and 2.7] and [123]). *Let* $n > 2$ *and* $1 \leqslant p \leqslant n-1$ *be fixed natural numbers. Suppose that the following conditions are satisfied*:

$$\begin{cases} f \in Car\big([0,T] \times \mathcal{D}\big) \textit{ and there exists } c > 0 \textit{ such that} \\ \quad c \leqslant f(t, x_0, \dots, x_{n-1}) \\ \textit{for a.e. } t \in [0,T] \textit{ and all } (x_0, \dots, x_{n-1}) \in \mathcal{D}, \end{cases} \tag{2.20}$$

$$\begin{cases} h \in Car\big([0,T] \times [0,\infty)\big) \textit{ is nondecreasing in its second variable and} \\ \quad \limsup_{z\to\infty} \dfrac{1}{z} \displaystyle\int_0^T h(t,z)\,\mathrm{d}t < \left(1 + \sum_{i=0}^{n-2} \frac{T^{n-i-1}}{(n-i-2)!}\right)^{-1}, \end{cases} \tag{2.21}$$

$$\begin{cases} \omega_i : (0,\infty) \to (0,\infty) \textit{ are nonincreasing and} \\ \quad \displaystyle\int_0^T \omega_i\big(t^{n-i}\big)\,\mathrm{d}t < \infty \quad \textit{for } 0 \leqslant i \leqslant n-1, \end{cases} \tag{2.22}$$

$$\begin{cases} f(t, x_0, \dots, x_{n-1}) \leqslant h\left(t, \displaystyle\sum_{i=0}^{n-1} |x_i|\right) + \displaystyle\sum_{i=0}^{n-1} \omega_i\big(|x_i|\big) \\ \textit{for a.e. } t \in [0,T] \textit{ and all } (x_0, \dots, x_{n-1}) \in \mathcal{D}. \end{cases} \tag{2.23}$$

Then the $(p, n-p)$ *conjugate problem* (2.18), (2.19) *has a solution* $u \in AC^{n-1}[0,T]$ *and* $u > 0$ *on* $(0,T)$.

SKETCH OF PROOF. *Step* 1. *Uniform integrability.*

Put

$$\mathcal{B} = \big\{u \in AC^{n-1}[0,T]\colon u \text{ satisfies (2.19) and } (-1)^p u^{(n)}(t) \geqslant c \\ \text{for a.e. } t \in [0,T]\big\},$$

where $c > 0$ is taken from (2.20). Conditions (2.20) and (2.22) guarantee that there exists a positive constant A such that

$$\int_0^T \omega_i\big(\big|u^{(i)}(t)\big|\big)\,\mathrm{d}t \leqslant A \quad \text{for each } u \in \mathcal{B} \text{ and } 0 \leqslant i \leqslant n-1$$

and that the set of functions $\{\omega_i(|u^{(i)}(t)|)\colon u \in \mathcal{B},\ 0 \leqslant i \leqslant n-1\}$ is uniformly integrable on $[0,T]$. Also, $u > 0$ on $(0,T)$ for each $u \in \mathcal{B}$.

Step 2. *Estimates of functions belonging to* $\mathcal{B}$.

By virtue of (2.21), there exists $r^* > 1$ such that the estimate $\|u\|_{C^{n-1}} < r^*$ holds for each function $u \in \mathcal{B}$ satisfying

$$u^{(n)}(t) \leqslant h\left(t, n + \sum_{i=0}^{n-1} \big|u^{(i)}(t)\big|\right) + \sum_{i=0}^{n-1} \big[\omega_i\big(\big|u^{(i)}(t)\big|\big) + \omega_i(1)\big] \\ \text{for a.e. } t \in [0,T].$$

Step 3. *Construction of regular problems to* (2.18), (2.19) *and properties of their solutions.*

For $m \in \mathbb{N}$, let $h_m \in Car([0,T] \times ([0,\infty) \times \mathbb{R}^{n-1}))$ be such that $h_m(t, x_0, \dots, x_{n-1}) = f(t, x_0, \dots, x_{n-1})$ for a.e. $t \in [0,T]$ and any $x_0 \geqslant \frac{1}{m}$, $|x_j| \geqslant \frac{1}{m}$, $1 \leqslant j \leqslant n-1$. Put

$$f_m(t, x_0, x_1, \dots, x_{n-1}) = h_m\bigl(t, \sigma_0(x_0), \sigma(x_1), \dots, \sigma(x_{n-1})\bigr)$$

for a.e. $t \in [0,T]$ and each $(x_0, x_1, \dots, x_{n-1}) \in \mathbb{R}^n$, where

$$\sigma_0(x) = \begin{cases} |x| & \text{if } |x| \leqslant r^*, \\ r^* & \text{if } |x| > r^*, \end{cases} \qquad \sigma(x) = \begin{cases} x & \text{if } |x| \leqslant r^*, \\ r^* \operatorname{sign} x & \text{if } |x| > r^*. \end{cases}$$

Now, the sequence of regular differential equations

$$(-1)^p u^{(n)} = f_m\bigl(t, u, \dots, u^{(n-1)}\bigr) \tag{2.24}$$

is considered. It follows from Theorem 2.1 that for each $m \in \mathbb{N}$ there exists a solution u_m of problem (2.24), (2.19) and $\|u_m\|_{C^{n-1}} < r^*$. Moreover, the sequence of functions $\{f_m(t, u_m(t), \dots, u_m^{(n-1)}(t))\}$ is uniformly integrable on $[0,T]$. By the Arzelà–Ascoli theorem there exists a subsequence $\{u_{k_m}\}$ converging in $C^{n-1}[0,T]$, $\lim_{m\to\infty} u_{k_m} = u$. Then $u \in C^{n-1}[0,T]$ satisfies (2.19) and for each $i \in \{1, \dots, n-1\}$, the function $u^{(n-i)}$ has a finite number of zeros $0 \leqslant a_{i1} < \dots < a_{i,p_i} \leqslant T$ and satisfies

$$\bigl|u^{(n-i)}(t)\bigr| \geqslant \frac{c}{i!}(t - a_{ik})^i \quad \text{for } t \in [a_{ik}, a_{i,k+1}]$$

or

$$\bigl|u^{(n-i)}(t)\bigr| \geqslant \frac{c}{i!}(a_{i,k+1} - t)^i \quad \text{for } t \in [a_{ik}, a_{i,k+1}]$$

(see [123]). Therefore $u \in AC^{n-1}[0,T]$ and u is a solution of problem (2.18), (2.19) due to Theorem 1.8. From Step 1 and (2.20) it follows that $u > 0$ on $(0,T)$. □

EXAMPLE. Let $p \in \{1, \dots, n-1\}$. Let $\alpha_i \in (0,1)$, $\beta_i \in (0, \frac{1}{n-i})$ and $b_i \in L_1[0,T]$, $c_i \in L_\infty[0,T]$ be nonnegative for $0 \leqslant i \leqslant n-1$. Also, let $\varphi \in L_1[0,T]$ and $\varphi(t) \geqslant c$ for a.e. $t \in [0,T]$ with $c > 0$. Then the differential equation

$$(-1)^p u^{(n)} = \varphi(t) + \sum_{i=0}^{n-1} \left(b_i(t) \bigl|u^{(i)}\bigr|^{\alpha_i} + \frac{c_i(t)}{|u^{(i)}|^{\beta_i}} \right)$$

has a solution $u \in AC^{n-1}[0,T]$ satisfying (2.19) and $u > 0$ on $(0,T)$.

2.3. (n, p) *boundary conditions*

Here we are concerned with the singular (n, p) problem

$$-u^{(n)} = f\big(t, u, \dots, u^{(n-1)}\big), \tag{2.25}$$

$$\begin{cases} u^{(i)}(0) = 0, & 0 \leqslant i \leqslant n-2, \\ u^{(p)}(T) = 0, & p \text{ fixed}, 0 \leqslant p \leqslant n-1, \end{cases} \tag{2.26}$$

where $n \geqslant 2$, $f \in Car([0, T] \times \mathcal{D})$, $\mathcal{D} = (0, \infty) \times (\mathbb{R} \setminus \{0\})^{n-2} \times \mathbb{R}$ and f may be singular at the value 0 of its space variables $x_0, \dots, x_{n-2}$. Notice that the $(n, 0)$ problem is simultaneously also the $(1, n-1)$ conjugate problem. For $f > 0$, solutions of problem (2.25), (2.26) have singular points of type I at $t = 0$, $t = T$ and also singular points of type II.

THEOREM 2.6 [14, Theorem 4.2]. *Suppose*

$$\begin{cases} f \in Car([0, T] \times \mathcal{D}) \textit{ and there exist positive } \psi \in L_1[0, T] \textit{ and} \\ K \in (0, \infty) \textit{ such that } \psi(t) \leqslant f(t, x_0, \dots, x_{n-1}) \quad \textit{for a.e. } t \in [0, T] \\ \textit{and each } (x_0, \dots, x_{n-1}) \in (0, K] \times (\mathbb{R} \setminus \{0\})^{n-2} \times \mathbb{R}, \end{cases} \tag{2.27}$$

$$\begin{cases} h_j \in L_1[0, T] \textit{ is nonnegative}, \omega_i : (0, \infty) \to (0, \infty) \textit{ is nonincreasing}, \\ \displaystyle\sum_{k=0}^{n-1} \frac{1}{(n-k-1)!} \int_0^T h_k(t) t^{n-k-1} \, \mathrm{d}t < 1, \quad \int_0^T \omega_i\big(t^{n-i-1}\big) \, \mathrm{d}t < \infty \\ \textit{for } 0 \leqslant j \leqslant n-1 \textit{ and } 0 \leqslant i \leqslant n-2, \end{cases} \tag{2.28}$$

$$\begin{cases} \textit{for a.e. } t \in [0, T] \textit{ and each } (x_0, \dots, x_{n-1}) \in \mathcal{D} \textit{ we have} \\ \qquad f(t, x_0, \dots, x_{n-1}) \leqslant \varphi(t) + \displaystyle\sum_{i=0}^{n-2} \omega_i\big(|x_i|\big) + \sum_{j=0}^{n-1} h_j(t)|x_j| \\ \textit{where } \varphi \in L_1[0, T] \textit{ is nonnegative.} \end{cases} \tag{2.29}$$

Then there exists a solution $u \in AC^{n-1}[0, T]$ *of problem* (2.25), (2.26) *with* $u^{(i)} > 0$ *on* $(0, T]$ *for* $0 \leqslant i \leqslant p-1$ (*if* $p \geqslant 1$) *and* $u^{(p)} > 0$ *on* $(0, T)$.

SKETCH OF PROOF. *Step* 1. *A priori bounds for solutions of problem* (2.25), (2.26).

Upper and lower bounds for solutions of problem (2.25), (2.26) and their derivatives are given by means of the Green function of the problem $-u^{(n)} = 0$, (2.26) (see, e.g., [1]).

Step 2. *Construction of auxiliary regular problems and properties of their solutions.*

Using Step 1, a sequence of regular differential equations

$$-u^{(n)} = f_m\big(t, u, \dots, u^{(n-1)}\big), \quad m \in \mathbb{N}, \ m \geqslant m_0 \geqslant \frac{1}{K}, \tag{2.30}$$

with $f_m \in Car([0, T] \times \mathbb{R}^n)$ is constructed. By the Leray–Schauder degree theory, we prove that for any $m \geqslant m_0$ problem (2.30), (2.26) has a solution u_m. The sequence

$\{u_m\}_{m=m_0}^{\infty}$ is bounded in $C^{n-1}[0,T]$ and $\{u_m^{(n-1)}\}_{m=m_0}^{\infty}$ is equicontinuous on $[0,T]$. The Arzelà–Ascoli theorem guarantees the existence of a subsequence $\{u_k\}_{k=1}^{\infty}$ of $\{u_m\}_{m=m_0}^{\infty}$ converging in $C^{n-1}[0,T]$ to a function u. Then $u \in C^{n-1}[0,T]$ satisfies (2.26) and $u^{(i)} > 0$ on $(0,T]$ for $0 \leqslant i \leqslant p-1$ (if $p \geqslant 1$) and $u^{(p)} > 0$ on $(0,T)$. Moreover, for each $i \in \{p+1,\dots,n-2\}$, the function $u^{(i)}$ has a unique zero ξ_i in $(0,T)$ $(0 < \xi_{n-2} < \xi_{n-1} < \cdots < \xi_{p+1} < T)$ and satisfies

$$u^{(i)}(t) \geqslant \begin{cases} ct^{n-i-1} & \text{for } t \in [0,\xi_{i+1}], \\ c(\xi_i - t) & \text{for } t \in [\xi_{i+1},\xi_i], \end{cases} \qquad u^{(i)}(t) \leqslant c(\xi_i - t) \quad \text{for } t \in [\xi_i, T]$$

where c is a positive constant. Since $\{f_k(t,u_k(t),\dots,u_k^{(n-1)}(t))\}$ is uniformly integrable on $[0,T]$, we can use Theorem 1.8 concluding that $u \in AC^{n-1}[0,T]$ and u is a solution of problem (2.25), (2.26). □

A related existence result for the singular (n,p) problem

$$\begin{cases} -u^{(n)} = \varphi(t)h\big(t,u,\dots,u^{(p-1)}\big), \\ u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant n-2, \\ u^{(p)}(1) = 0, \quad p \text{ fixed}, \ 1 \leqslant p \leqslant n-1 \end{cases} \tag{2.31}$$

was presented in [12] with h continuous and positive on $[0,1] \times (0,\infty)^p$ and $\varphi \in C^0(0,1) \cap L_1[0,1]$ positive on $(0,1)$. In this setting solutions of problem (2.31) cannot have singular points of type II. The result is the following.

THEOREM 2.7 [12, Theorem 3.1]. *Suppose that* (2.11)–(2.14) *and* (2.16) *hold and*

$$\begin{cases} \displaystyle\int_0^1 \varphi(t) g_i\big(k_i t^{n-1-i}\big)\,\mathrm{d}t < \infty \quad \textit{for each } i = 0,\dots,p-1, \\ \textit{where } k_i > 0, \ i = 0,\dots,p-1, \ \textit{are constants.} \end{cases}$$

Then problem (2.31) *has a solution* $u \in C^{n-1}[0,1] \cap C^n(0,1)$ *with* $u^{(j)} > 0$ *on* $(0,1]$ *for* $0 \leqslant j \leqslant p-1$.

2.4. *Sturm–Liouville conditions*

We are now concerned with the Sturm–Liouville problem for the nth-order differential equation (2.25), $n \geqslant 3$, and the boundary conditions

$$\begin{cases} u^{(i)}(0) = 0, \quad 0 \leqslant i \leqslant n-3, \\ \alpha u^{(n-2)}(0) - \beta u^{(n-1)}(0) = 0, \\ \gamma u^{(n-2)}(T) + \delta u^{(n-1)}(T) = 0, \end{cases} \tag{2.32}$$

where $\alpha, \gamma > 0$ and $\beta, \delta \geqslant 0$. Notice that the function f in Eq. (2.25) may be singular at the value 0 of its space variables $x_0, \dots, x_{n-1}$. If $f > 0$, solutions of problem (2.25), (2.32) have singular points of type I at the end points of the interval $[0, T]$ and also singular points of type II.

We will impose the following conditions on the function f in (2.25):

$$\begin{cases} f \in Car\big([0,T] \times \mathcal{D}\big) \text{ where } \mathcal{D} = (0,\infty)^{n-1} \times \big(\mathbb{R} \setminus \{0\}\big) \\ \text{and there exist positive constants } \varepsilon \text{ and } r \text{ such that} \\ \quad \varepsilon t^r \leqslant f(t, x_0, \dots, x_{n-1}) \\ \text{for a.e. } t \in [0,T] \text{ and each } (x_0, \dots, x_{n-1}) \in \mathcal{D}; \end{cases} \tag{2.33}$$

$$\begin{cases} \text{for a.e. } t \in [0,T] \text{ and each } (x_0, \dots, x_{n-1}) \in \mathcal{D}, \\ \quad f(t, x_0, \dots, x_{n-1}) \leqslant \varphi(t) + \displaystyle\sum_{i=0}^{n-1} \omega_i\big(|x_i|\big) + \sum_{i=0}^{n-1} h_i(t)|x_i|^{\alpha_i} \\ \text{with } \alpha_i \in (0,1),\ \varphi, h_i \in L_1[0,T] \text{ nonnegative}, \\ \omega_i : (0,\infty) \to (0,\infty) \text{ nonincreasing, } 0 \leqslant i \leqslant n-1, \text{ and} \\ \quad \displaystyle\int_0^T \omega_{n-1}\big(t^{r+1}\big)\,\mathrm{d}t < \infty, \quad \int_0^T \omega_i\big(t^{n-i-1}\big)\,\mathrm{d}t < \infty \quad \text{for } 0 \leqslant i \leqslant n-2; \end{cases} \tag{2.34}$$

$$\begin{cases} \text{for a.e. } t \in [0,T] \text{ and each } (x_0, \dots, x_{n-1}) \in \mathcal{D}, \\ \quad f(t, x_0, \dots, x_{n-1}) \leqslant \varphi(t) + \displaystyle\sum_{i=0, i \neq n-2}^{n-1} \omega_i\big(|x_i|\big) + q(t)\omega_{n-2}\big(|x_{n-2}|\big) \\ \qquad + \displaystyle\sum_{i=0}^{n-1} h_i(t)|x_i|^{\alpha_i} \\ \text{with } \alpha_i \in (0,1),\ \varphi, q, h_i \in L_1[0,T] \text{ nonnegative}, \\ \omega_i : (0,\infty) \to (0,\infty) \text{ nonincreasing, } 0 \leqslant i \leqslant n-1, \text{ and} \\ \quad \displaystyle\int_0^T \omega_{n-1}\big(t^{r+1}\big)\,\mathrm{d}t < \infty, \quad \int_0^T \omega_j\big(t^{n-j-2}\big)\,\mathrm{d}t < \infty \quad \text{for } 0 \leqslant j \leqslant n-3. \end{cases} \tag{2.35}$$

The next two theorems show that our sufficient conditions for the solvability of problem (2.25), (2.32) with $\min\{\beta, \delta\} > 0$ are weaker then those for this problem with $\min\{\beta, \delta\} = 0$.

THEOREM 2.8 [120, Theorem 4.1]. *Let conditions* (2.33) *and* (2.34) *be satisfied and let* $\min\{\beta, \delta\} = 0$. *Then problem* (2.25), (2.32) *has a solution* $u \in AC^{n-1}[0,T]$, $u^{(n-2)} > 0$ *on* $(0,T)$ *and* $u^{(j)} > 0$ *on* $(0,T]$ *for* $0 \leqslant j \leqslant n-3$.

SKETCH OF PROOF. *Step* 1. *A priori bounds for the solution of* (2.25), (2.32).

By (2.33) and by the properties of the Green function to problem

$$-u''=0,\quad \alpha u(0)-\beta u'(0)=0,\quad \gamma u(T)+\delta u'(T)=0,$$

the existence of a positive constant A is proved such that for any function $u\in AC^{n-1}[0,T]$ satisfying (2.32) and $-u^{(n)}(t)\geqslant \varepsilon t^r$ for a.e. $t\in[0,T]$ we have

$$u^{(n-2)}(t)\geqslant\begin{cases}At & \text{for } t\in[0,\frac{T}{2}],\\ A(T-t) & \text{for } t\in(\frac{T}{2},T],\end{cases}\tag{2.36}$$

$$u^{(j)}(t)\geqslant\frac{A}{4(n-j-1)!}t^{n-j-1}\quad\text{for } t\in[0,T] \text{ and } 0\leqslant j\leqslant n-3\tag{2.37}$$

and

$$u^{(n-1)}(t)\begin{cases}\geqslant\dfrac{\varepsilon}{r+1}(\xi-t)^{r+1} & \text{for } t\in[0,\xi],\\ <-\dfrac{\varepsilon}{r+1}(t-\xi)^{r+1} & \text{for } t\in(\xi,T],\end{cases}\tag{2.38}$$

where $\xi\in(0,T)$ (depending on the solution u) is the unique zero of $u^{(n-1)}$. Condition (2.34) guarantees the existence of a positive constant S such that $\|u\|_{C^{n-1}}\leqslant S$ for any solution u to (2.25), (2.32).

Step 2. *Construction of regular differential equations.*

Using Step 1, a sequence of regular differential equations (2.30) is constructed where $f_m\in Car([0,T]\times\mathbb{R}^n)$,

$$f_m(t,x_0,\dots,x_{n-1})=f(t,x_0,\dots,x_{n-1})$$

for a.e. $t\in[0,T]$ and all $(x_0,\dots,x_{n-1})\in\mathbb{R}^n$ such that

$$\frac{1}{m}\leqslant x_j\leqslant S+1\quad\text{if } 0\leqslant j\leqslant n-2,\qquad \frac{1}{m}\leqslant|x_{n-1}|\leqslant S+1$$

and

$$\sup\bigl\{f_m(t,x_0,\dots,x_{n-1})\colon (x_0,\dots,x_{n-1})\in\mathbb{R}^n\bigr\}\in L_1[0,T]\quad\text{for all } m\in\mathbb{N}.$$

Then Theorem 2.1 guarantees that the regular problem (2.30), (2.32) has a solution u_m which satisfies (2.36)–(2.38) (with u_m instead of u).

Step 3. *Properties of solutions to regular problems* (2.30), (2.32).

The sequence $\{u_m\}$ is considered. It is proved that $\{u_m\}$ is bounded in $C^{n-1}[0,T]$ and, by (2.34), the sequence of functions $\{f_m(t,u_m(t),\dots,u_m^{(n-1)}(t))\}$ is uniformly integrable on $[0,T]$, which implies that $\{u_m^{(n-1)}\}$ is equicontinuous on $[0,T]$. Hence a subsequence

$\{u_{k_m}\}$ converging in $C^{n-1}[0,T]$ exists and let $\lim_{m\to\infty} u_{k_m} = u$. Since u satisfies (2.36)–(2.38), the functions $u^{(i)}$, $0 \leqslant i \leqslant n-1$, have a finite number of zeros in $[0,T]$. Therefore, by Theorem 1.8, $u \in AC^{n-1}[0,T]$ and u is a solution of problem (2.25), (2.32) such that $u^{(j)} > 0$ on $(0,T]$ for $0 \leqslant j \leqslant n-3$ and $u^{(n-2)} > 0$ on $(0,T)$. ☐

THEOREM 2.9 [120, Theorem 4.2]. *Let conditions* (2.33) *and* (2.35) *be satisfied and let* $\min\{\beta,\delta\} > 0$. *Then there exists a solution* $u \in AC^{n-1}[0,T]$ *of problem* (2.25), (2.32) *such that* $u^{(n-2)} > 0$ *on* $[0,T]$ *and* $u^{(j)} > 0$ *on* $(0,T]$ *for* $0 \leqslant j \leqslant n-3$.

SKETCH OF PROOF. Since $\min\{\beta,\delta\} > 0$, there is a positive constant B such that $u^{(n-2)} \geqslant B$ on $[0,T]$ for any solution u of problem (2.25), (2.32). Further, the inequalities (2.37) with B instead of A and (2.38) hold. Next we argue as in the sketch of proof to Theorem 2.8. ☐

2.5. *Lidstone conditions*

Let $\mathbb{R}_- = (-\infty,0)$, $\mathbb{R}_+ = (0,\infty)$ and $\mathbb{R}_0 = \mathbb{R}\setminus\{0\}$. Here we will consider the singular problem

$$(-1)^n u^{(2n)} = f\big(t,u,\dots,u^{(2n-2)}\big), \tag{2.39}$$

$$u^{(2j)}(0) = u^{(2j)}(T) = 0, \quad 0 \leqslant j \leqslant n-1, \tag{2.40}$$

where $n \geqslant 1$ and $f \in Car([0,T]\times\mathcal{D})$ with

$$\mathcal{D} = \begin{cases} \underbrace{\mathbb{R}_+ \times \mathbb{R}_0 \times \mathbb{R}_- \times \mathbb{R}_0 \times \cdots \times \mathbb{R}_+}_{4k-3} & \text{if } n = 2k-1,\\ \underbrace{\mathbb{R}_+ \times \mathbb{R}_0 \times \mathbb{R}_- \times \mathbb{R}_0 \times \cdots \times \mathbb{R}_-}_{4k-1} & \text{if } n = 2k \end{cases}$$

(for $n = 1, 2$ and 3 we have $\mathcal{D} = \mathbb{R}_+$, $\mathcal{D} = \mathbb{R}_+ \times \mathbb{R}_0 \times \mathbb{R}_-$ and $\mathcal{D} = \mathbb{R}_+ \times \mathbb{R}_0 \times \mathbb{R}_- \times \mathbb{R}_0 \times \mathbb{R}_+$, respectively). The function f may be singular at the value 0 of its space variables $x_0,\dots,x_{2n-2}$. If f is positive on $[0,T]\times\mathcal{D}$, solutions of problem (2.39), (2.40) have singular points of type I at $t=0$ and $t=T$ as well as singular points of type II.

THEOREM 2.10 [14, Theorem 4.1]. *Let the following conditions be satisfied*:

$$\begin{cases} f \in Car([0,T]\times\mathcal{D}) \textit{ and there exists } \varphi \in L_1[0,T] \textit{ such that}\\ \quad 0 < \varphi(t) \leqslant f(t,x_0,\dots,x_{2n-2})\\ \textit{for a.e. } t \in [0,T] \textit{ and each } (x_0,\dots,x_{2n-2}) \in \mathcal{D}; \end{cases} \tag{2.41}$$

$$\begin{cases} \textit{for } \ 0 \leqslant j \leqslant 2n-2, \ h_j \in L_1[0,T] \textit{ are nonnegative and} \\ \displaystyle\sum_{j=0}^{n-1} \frac{T^{2(n-j)-3}}{6^{n-j-1}} \int_0^T t(T-t)h_{2j}(t)\,\mathrm{d}t \\ \qquad \displaystyle + \sum_{j=0}^{n-2} \frac{T^{2(n-j-2)}}{6^{n-j-2}} \int_0^T t(T-t)h_{2j+1}(t)\,\mathrm{d}t < 1 \\ (\textit{here } \sum_{j=0}^{n-2} = 0 \textit{ if } n = 1); \end{cases} \tag{2.42}$$

$$\begin{cases} \omega_j : \mathbb{R}_+ \to \mathbb{R}_+ \textit{ are nonincreasing, } \Lambda > 0 \textit{ and} \\ \displaystyle\int_0^T \omega_j(s)\,\mathrm{d}s < \infty, \qquad \omega_j(uv) \leqslant \Lambda\omega_j(u)\omega_j(v) \\ \textit{for } 0 \leqslant j \leqslant 2n-2 \textit{ and } u, v \in \mathbb{R}_+; \end{cases} \tag{2.43}$$

$$\begin{cases} \displaystyle f(t, x_0, \ldots, x_{2n-2}) \leqslant \psi(t) + \sum_{j=0}^{2n-2} \omega_j\big(|x_j|\big) + \sum_{j=0}^{2n-2} h_j(t)|x_j| \\ \textit{for a.e. } t \in [0,T] \textit{ and each } (x_0, \ldots, x_{2n-2}) \in \mathcal{D}, \\ \textit{where } \psi \in L_1[0,T] \textit{ is nonnegative.} \end{cases} \tag{2.44}$$

Then problem (2.39), (2.40) *has a solution* $u \in AC^{2n-1}[0,T]$ *and*

$$(-1)^j u^{(2j)} > 0 \quad \textit{on } (0,T) \quad \textit{for } 0 \leqslant j \leqslant n-1.$$

SKETCH OF PROOF. *Step* 1. *A priori bounds for solutions of problem* (2.39), (2.40).

Using (2.41) and the properties of the Green functions to problems $u^{(2j)} = 0$, $u^{(2i)}(0) = u^{(2i)}(T) = 0$, $0 \leqslant i \leqslant j-1$, it is proved that for any solution u of problem (2.39), (2.40) and for each j, $0 \leqslant j \leqslant n-1$, the inequality $(-1)^j u^{(2j)} > 0$ holds on $(0,T)$ and the function $(-1)^j u^{(2j+1)}$ is decreasing on $[0,T]$ and vanishes at a unique $\xi_j \in (0,T)$ (depending on u). Moreover,

$$\big|u^{(2j)}(t)\big| \geqslant A\frac{T^{2(n-j)-5}}{30^{n-j-1}} t(T-t), \quad t \in [0,T],\ 0 \leqslant j \leqslant n-1,$$

and (if $n > 1$)

$$\big|u^{(2j+1)}(t)\big| \geqslant A\frac{T^{2(n-j)-7}}{30^{n-j-2}} \left| \int_{\xi_j}^t s(T-s)\,\mathrm{d}s \right|, \quad t \in [0,T],\ 0 \leqslant j \leqslant n-2,$$

where $A = \int_0^T t(T-t)\varphi(t)\,\mathrm{d}t$.

Step 2. *Construction of a sequence of regular problems.*

For each $m \in \mathbb{N}$, define $f_m \in Car([0,T] \times \mathbb{R}^{2n-1})$ satisfying

$$f_m(t, x_0, \ldots, x_{2n-2}) = f(t, x_0, \ldots, x_{2n-2})$$

for a.e. $t \in [0,T]$ and each $(x_0,\dots,x_{2n-2}) \in \mathcal{D}$, $|x_j| \geqslant \frac{1}{m}$, $0 \leqslant j \leqslant 2n-2$. By virtue of (2.44) and a fixed point theorem of Leray–Schauder type (see, e.g., [50, Corollary 8.1]), for each $m \in \mathbb{N}$ there exists a solution u_m of the regular differential equation $(-1)^n u^{(2n)} = f_m(t,u,\dots,u^{(2n-2)})$ satisfying (2.40). Further, $\|u_m\|_{C^{2n-1}} \leqslant B$ for each $m \in \mathbb{N}$ where B is a positive constant and the sequence $\{f_m(t,u_m(t),\dots,u_m^{(2n-2)}(t))\}$ is uniformly integrable on $[0,T]$ due to (2.43) and (2.44).

Step 3. *Limit processes.*

From Step 2 it follows that $\{u_m\}$ is bounded in $C^{2n-1}[0,T]$. Hence, by the Arzelà–Ascoli theorem and a compactness principle, there exists its subsequence $\{u_{k_m}\}$ which converges in $C^{2n-2}[0,T]$ and $\{u_{k_m}^{(2n-1)}(0)\}$ converges in $\mathbb{R}$. Let $\lim_{m\to\infty} u_{k_m} = u$, $\lim_{m\to\infty} u_{k_m}^{(2n-1)}(0) = C$. Then $u \in C^{2n-2}[0,T]$ satisfies (2.40) and, by Step 1, the functions $u^{(i)}$, $0 \leqslant i \leqslant 2n-1$, have a finite number of zeros on $[0,T]$. Therefore, by Theorem 1.8, $u \in AC^{2n-1}[0,T]$ and u is a solution of (2.39). Moreover, $(-1)^j u^{(2j)} > 0$ on $(0,T)$ for $0 \leqslant j \leqslant n-1$. □

2.6. *Historical and bibliographical notes*

Higher order boundary value problems with space singularities have been mostly studied by Agarwal, Eloe, Henderson, Lakshmikantham, O'Regan, Rachůnková and Staněk.

Positive solutions in the set $C^{n-1}[0,1] \cap C^n(0,1)$ were obtained in [7] for the singular $(p,n-p)$ right focal problem $(-1)^{n-p}u^{(n)} = \varphi(t)f(t,u)$, (2.6) on the interval $[0,1]$ where $f \in C^0([0,1]\times(0,\infty))$ is positive and may be singular at $u=0$. In [7] the authors also discussed applications in fluid theory and boundary layer theory.

Singular $(p,n-p)$ conjugate problems were studied in [5], [58] (with $p=1$) and [59] for the differential equation $(-1)^{n-p}u^{(n)} = f(t,u)$ where $f \in C^0((0,1)\times(0,\infty))$ and may be singular at $u=0$. Here positive solutions on $(0,1)$ belong to the class $C^{n-1}[0,1] \cap C^n(0,1)$. Existence results in [58] and [59] are proved by a fixed point theorem for operators that are decreasing with respect to a cone and those in [5] by a nonlinear alternative of Leray–Schauder.

The existence of positive solutions on $(0,1)$ to singular Sturm–Liouville problems for the differential equation $-u^{(n)} = f(t,u,\dots,u^{(n-2)})$ can be found in [20]. There $f \in C((0,1)\times(0,\infty)^{n-1})$ is positive and may be singular at the value 0 of all its space variables. The results are proved by a fixed point theorem for mappings that are decreasing with respect to a cone in a Banach space.

Existence results for positive solutions to singular $(p,n-p)$ focal, conjugate and (n,p) problems are given in [8,9] for differential equations with the right-hand side $\varphi(t)f(t,u)$ where $f \in C([0,1]\times(0,\infty))$ and may be singular at $u=0$. The paper [8] is the first to establish conditions for the existence of two solutions to singular $(p,n-p)$ focal and (n,p) problems. Further multiple solutions for singular $(p,n-p)$ focal, conjugate and (n,p) problems are established in [9]. The technique presented in [8,9] to guarantee the existence of twin solutions to the singular problems combines (i) a nonlinear alternative of Leray–Schauder, (ii) the Krasnoselskii fixed point theorem in a cone, and (iii) lower type inequalities.

Notice that in all cited papers singular points corresponding to solutions of the singular problems under discussion are only of type I.

3. Principles of solvability of singular second order BVPs with ϕ-Laplacian

In the theory of partial differential equations, the p-Laplace equation

$$\operatorname{div}\bigl(|\nabla v|^{p-2}\nabla v\bigr) = h\bigl(|x|, v\bigr) \tag{3.1}$$

is considered. Here ∇ is the gradient, $p > 1$ and $|x|$ is the Euclidean norm in $\mathbb{R}^n$ of $x = (x_1, \dots, x_n)$, $n > 1$. Radially symmetric solutions of (3.1) (i.e., solutions that depend only on the variable $r = |x|$) satisfy the ordinary differential equation

$$r^{1-n}\bigl(r^{n-1}|v'|^{p-2}v'\bigr)' = h(r, v), \quad ' = \frac{\mathrm{d}}{\mathrm{d}r}. \tag{3.2}$$

If $p = n$, the change of variables $t = \ln r$ transforms (3.2) into the equation

$$\bigl(|u'|^{p-2}u'\bigr)' = \mathrm{e}^{nt} h(\mathrm{e}^t, u), \quad ' = \frac{\mathrm{d}}{\mathrm{d}t}$$

and for $p \neq n$, the change of variables $t = r^{(p-n)/(p-1)}$ transforms (3.2) into the equation

$$\bigl(|u'|^{p-2}u'\bigr)' = \left|\frac{p-1}{p-n}\right|^p t^{\frac{p-n}{p(1-n)}} h\bigl(t^{\frac{p-1}{p-n}}, u\bigr), \quad ' = \frac{\mathrm{d}}{\mathrm{d}t}.$$

The operator $u \to (|u'|^{p-2}u')'$ is called the (one-dimensional) *p-Laplacian*. Its natural generalization is the *ϕ-Laplacian*

$$u \to \bigl(\phi(u')\bigr)',$$
$$\text{where } \phi : \mathbb{R} \to \mathbb{R} \text{ is an increasing homeomorphism and } \phi(\mathbb{R}) = \mathbb{R}. \tag{3.3}$$

Therefore Eq. (3.1) was a motivation for discussing the solutions to the differential equations

$$\bigl(|u'|^{p-2}u'\bigr)' = f(t, u, u')$$

and

$$\bigl(\phi(u')\bigr)' = f(t, u, u')$$

with the p-Laplacian and the ϕ-Laplacian, respectively.

In the next part of this section, we treat problems for second order differential equations with the ϕ-Laplacian on the left-hand side and with nonlinearities on the right-hand sides which can have singularities in their space variables. Boundary conditions under discussion are generally nonlinear and nonlocal. Using regularization and sequential techniques we present general existence principles for solvability of regular and singular problems.

3.1. *Regularization of singular problems with ϕ-Laplacian*

We discuss singular differential equations of the form

$$\big(\phi(u')\big)' = f(t, u, u') \tag{3.4}$$

with the ϕ-Laplacian. Here $f \in Car([0,T] \times \mathcal{D})$, the set $\mathcal{D} = \mathcal{D}_1 \times \mathcal{D}_2 \subset \mathbb{R}^2$ is not necessarily closed, $\mathcal{D}_1$, $\mathcal{D}_2$ are intervals and f may have singularities in its space variables on the boundary $\partial\mathcal{D}_j$ of $\mathcal{D}_j$ $(j = 1, 2)$. We note that f has a singularity on $\partial\mathcal{D}_j$ in its space variable x_j if there is an $a_j \in \partial\mathcal{D}_j$ such that for a.e. $t \in [0,T]$ and some $x_{3-j} \in \mathcal{D}_{3-j}$,

$$\limsup_{x_j \to a_j,\ x_j \in \mathcal{D}_j} \big|f(t, x_1, x_2)\big| = \infty.$$

Let $\mathcal{A}$ denote the set of functionals $\alpha : C^1[0,T] \to \mathbb{R}$ which are
(a) continuous and
(b) bounded, that is, $\alpha(\Omega)$ is bounded (in $\mathbb{R}$) for any bounded $\Omega \subset C^1[0,T]$.
For $\alpha, \beta \in \mathcal{A}$, consider the (generally nonlinear and nonlocal) boundary conditions

$$\alpha(u) = 0, \quad \beta(u) = 0. \tag{3.5}$$

DEFINITION 3.1. A function $u : [0,T] \to \mathbb{R}$ is said to be a *solution of problem* (3.4), (3.5) if $\phi(u') \in AC[0,T]$, u satisfies the boundary conditions (3.5) and $(\phi(u'(t)))' = f(t, u(t), u'(t))$ holds for a.e. $t \in [0,T]$.

Special cases of the boundary conditions (3.5) are the Dirichlet (Neumann; mixed; periodic and Sturm–Liouville type) boundary conditions which we get setting $\alpha(x) = x(0)$, $\beta(x) = x(T)$ ($\alpha(x) = x'(0)$, $\beta(x) = x'(T)$; $\alpha(x) = x(0)$, $\beta(x) = x'(T)$; $\alpha(x) = x(0) - x(T)$, $\beta(x) = x'(0) - x'(T)$ and $\alpha(x) = a_0 x(0) + a_1 x'(0)$, $\beta(x) = b_0 x(T) + b_1 x'(T)$).

In order to obtain an existence result for problem (3.4), (3.5), we use regularization and sequential techniques. For this purpose consider a sequence of regular differential equations

$$\big(\phi(u')\big)' = f_n(t, u, u') \tag{3.6}$$

where $f_n \in Car([0,T] \times \mathbb{R}^2)$. The function f_n is constructed in such a way that

$$f_n(t, x, y) = f(t, x, y) \quad \text{for a.e. } t \in [0,T] \text{ and all } (x, y) \in \mathcal{Q}_n$$

where $\mathcal{Q}_n \subset \mathcal{D}$ and roughly speaking $\mathcal{Q}_n$ converges to $\mathcal{D}$ as $n \to \infty$.

Let $h \in Car([0,T] \times \mathbb{R}^2)$ and consider the regular differential equation

$$\big(\phi(u')\big)' = h(t,u,u'). \tag{3.7}$$

A function $u : [0,T] \to \mathbb{R}$ is called a *solution of the regular problem* (3.7), (3.5) if $\phi(u') \in AC[0,T]$, u satisfies (3.5) and $(\phi(u'(t)))' = h(t,u(t),u'(t))$ for a.e. $t \in [0,T]$.

The next general existence principle can be used for solving the regular problem (3.7), (3.5).

THEOREM 3.2 (General existence principle for regular problems). *Assume* (3.3), $h \in Car([0,T] \times \mathbb{R}^2)$ *and* $\alpha, \beta \in \mathcal{A}$. *Suppose there exist positive constants* S_0 *and* S_1 *such that*

$$\|u\|_\infty < S_0, \quad \|u'\|_\infty < S_1$$

for all solutions u to the problem

$$\big(\phi(u')\big)' = \lambda h(t,u,u'), \quad \alpha(u) = 0, \quad \beta(u) = 0 \tag{3.8}$$

and each $\lambda \in [0,1]$. *Also assume there exist positive constants* Λ_0 *and* Λ_1 *such that*

$$|A| < \Lambda_0, \quad |B| < \Lambda_1 \tag{3.9}$$

for all solutions $(A,B) \in \mathbb{R}^2$ *of the system*

$$\begin{cases} \alpha(A+Bt) - \mu\alpha(-A-Bt) = 0, \\ \beta(A+Bt) - \mu\beta(-A-Bt) = 0 \end{cases} \tag{3.10}$$

and each $\mu \in [0,1]$. *Then problem* (3.7), (3.5) *has a solution.*

PROOF. Set

$$\Omega = \big\{x \in C^1[0,T]:\ \|x\|_\infty < \max\{S_0, \Lambda_0 + \Lambda_1 T\},\ \|x'\|_\infty < \max\{S_1, \Lambda_1\}\big\}.$$

Then Ω is an open, bounded and symmetric with respect to $0 \in C^1[0,T]$ subset of the Banach space $C^1[0,T]$. Define an operator $\mathcal{P} : [0,1] \times \overline{\Omega} \to C^1[0,T]$ by the formula

$$\begin{aligned} \mathcal{P}(\lambda,x)(t) &= x(0) + \alpha(x) \\ &\quad + \int_0^t \phi^{-1}\left(\phi\big(x'(0) + \beta(x)\big) + \lambda \int_0^s h\big(v, x(v), x'(v)\big)\,\mathrm{d}v\right)\mathrm{d}s. \end{aligned} \tag{3.11}$$

A standard argument shows that $\mathcal{P}$ is a continuous operator. We claim that $\mathcal{P}([0,1] \times \overline{\Omega})$ is compact in $C^1[0,T]$. Indeed, since $\overline{\Omega}$ is bounded in $C^1[0,T]$, we have

$$\big|\alpha(x)\big| \leqslant r, \quad |\beta(x)| \leqslant r, \quad \big|h\big(t, x(t), x'(t)\big)\big| \leqslant \varrho(t)$$

for a.e. $t \in [0,T]$ and $x \in \overline{\Omega}$, where r is a positive constant and $\varrho \in L_1[0,T]$. Set $K = \max\{S_1, \Lambda_1\} + r$ and $V = \max\{|\phi(-K)|, |\phi(K)|\}$. Then

$$\begin{aligned} \left|\mathcal{P}(\lambda,x)(t)\right| &\leqslant \max\{S_0, \Lambda_0 + \Lambda_1 T\} + r \\ &\quad + T\max\left\{\left|\phi^{-1}\left(-V - \|\varrho\|_1\right)\right|, \left|\phi^{-1}\left(V + \|\varrho\|_1\right)\right|\right\}, \\ \left|\mathcal{P}(\lambda,x)'(t)\right| &\leqslant \max\left\{\left|\phi^{-1}\left(-V - \|\varrho\|_1\right)\right|, \left|\phi^{-1}(V + \|\varrho\|_1)\right|\right\} \end{aligned}$$

and

$$\left|\phi\left(\mathcal{P}(\lambda,x)'(t_2)\right) - \phi\left(\mathcal{P}(\lambda,x)'(t_1)\right)\right| \leqslant \left|\int_{t_1}^{t_2} \varrho(t)\,\mathrm{d}t\right|$$

for $t, t_1, t_2 \in [0,T]$ and $(\lambda, x) \in [0,1] \times \overline{\Omega}$. Hence $\mathcal{P}([0,1] \times \overline{\Omega})$ is bounded in $C^1[0,T]$ and $\{\phi[\mathcal{P}(\lambda,x)']\}$ is equicontinuous on $[0,T]$. The mapping ϕ^{-1} being an increasing homeomorphism from $\mathbb{R}$ onto $\mathbb{R}$, we deduce from

$$\left|\mathcal{P}(\lambda,x)'(t_2) - \mathcal{P}(\lambda,x)'(t_1)\right| = \left|\phi^{-1}\left(\phi\left(\mathcal{P}(\lambda,x)'(t_2)\right)\right) - \phi^{-1}\left(\phi\left(\mathcal{P}(\lambda,x)'(t_1)\right)\right)\right|$$

that $\{\mathcal{P}(\lambda,x)'\}$ is also equicontinuous on $[0,T]$. Now the Arzelà–Ascoli theorem shows that $\mathcal{P}([0,1] \times \overline{\Omega})$ is compact in $C^1[0,T]$. Thus $\mathcal{P}$ is a compact operator.

Suppose that x_0 is a fixed point of the operator $\mathcal{P}(1,\cdot)$. Then

$$\begin{aligned} x_0(t) &= x_0(0) + \alpha(x_0) \\ &\quad + \int_0^t \phi^{-1}\left(\phi\left(x_0'(0) + \beta(x_0)\right) + \int_0^s h\left(v, x_0(v), x_0'(v)\right)\mathrm{d}v\right)\mathrm{d}s. \end{aligned}$$

Hence $\alpha(x_0) = 0$, $\beta(x_0) = 0$ and x_0 is a solution of the differential equation (3.7). Therefore x_0 is a solution of problem (3.7), (3.5) and to prove our theorem, it suffices to show that

$$\deg\left(\mathcal{I} - \mathcal{P}(1,\cdot), \Omega\right) \neq 0 \tag{3.12}$$

where "deg" stands for the Leray–Schauder degree and $\mathcal{I}$ is the identity operator on $C^1[0,T]$. To see this let a compact operator $\mathcal{K}\colon [0,1] \times \overline{\Omega} \to C^1[0,T]$ be given by

$$\mathcal{K}(\mu,x)(t) = x(0) + \alpha(x) - \mu\alpha(-x) + \left[x'(0) + \beta(x) - \mu\beta(-x)\right]t.$$

Then $\mathcal{K}(1,\cdot)$ is odd (i.e. $\mathcal{K}(1,-x) = -\mathcal{K}(1,x)$ for $x \in \overline{\Omega}$) and

$$\mathcal{K}(0,\cdot) = \mathcal{P}(0,\cdot). \tag{3.13}$$

If $\mathcal{K}(\mu_0, x_0) = x_0$ for some $\mu_0 \in [0,1]$ and $x_0 \in \overline{\Omega}$, then

$$\begin{aligned} x_0(t) &= x_0(0) + \alpha(x_0) - \mu_0\alpha(-x_0) + \left[x_0'(0) + \beta(x_0) - \mu_0\beta(-x_0)\right]t, \\ &\quad t \in [0,T]. \end{aligned}$$

Thus $x_0(t) = A_0 + B_0 t$ where $A_0 = x_0(0) + \alpha(x_0) - \mu_0\alpha(-x_0)$ and $B_0 = x_0'(0) + \beta(x_0) - \mu_0\beta(-x_0)$, so $\alpha(x_0) - \mu_0\alpha(-x_0) = 0$, $\beta(x_0) - \mu_0\beta(-x_0) = 0$. Hence

$$\alpha(A_0 + B_0 t) - \mu_0\alpha(-A_0 - B_0 t) = 0,$$
$$\beta(A_0 + B_0 t) - \mu_0\beta(-A_0 - B_0 t) = 0.$$

Therefore $|A_0| < \Lambda_0$, $|B_0| < \Lambda_1$ and $\|x_0\|_\infty < \Lambda_0 + \Lambda_1 T$, $\|x_0'\|_\infty < \Lambda_1$, which gives $x_0 \notin \partial\Omega$. Now, by the Borsuk antipodal theorem and a homotopy property,

$$\deg\bigl(\mathcal{I} - \mathcal{K}(0,\cdot), \Omega\bigr) = \deg\bigl(\mathcal{I} - \mathcal{K}(1,\cdot), \Omega\bigr) \neq 0. \tag{3.14}$$

Finally, assume that $\mathcal{P}(\lambda_*, x_*) = x_*$ for some $\lambda_* \in [0, 1]$ and $x_* \in \overline{\Omega}$. Then x_* is a solution of problem (3.8) with $\lambda = \lambda_*$ and, by our assumptions, $\|x_*\|_\infty < S_0$ and $\|x_*'\|_\infty < S_1$. Hence $x_* \notin \partial\Omega$ and the homotopy property yields

$$\deg\bigl(\mathcal{I} - \mathcal{P}(0,\cdot), \Omega\bigr) = \deg\bigl(\mathcal{I} - \mathcal{P}(1,\cdot), \Omega\bigr).$$

This, with (3.13) and (3.14), implies (3.12). Therefore, problem (3.7), (3.5) has a solution. ☐

REMARK 3.3. If functionals $\alpha, \beta \in \mathcal{A}$ are linear, then system (3.10) has the form

$$A\alpha(1) + B\alpha(t) = 0,$$
$$A\beta(1) + B\beta(t) = 0.$$

All of its solutions (A, B) are bounded if and only if $\alpha(1)\beta(t) - \alpha(t)\beta(1) \neq 0$ (and then $(A, B) = (0, 0)$). This is satisfied for example for the Dirichlet conditions but not for the periodic ones.

3.2. *General existence principle for singular BVPs with ϕ-Laplacian*

Let us consider the singular problem (3.4), (3.5). By regularization and sequential techniques, we construct an approximating sequence of regular problems (3.6), (3.5) for whose solvability Theorem 3.2 can be used. Existence results for the singular problem (3.4), (3.5) can be proved by the following two general existence principles. The first principle uses the Vitali convergence theorem, the other is based on a combination of the Lebesgue dominated convergence theorem and the Fatou theorem.

THEOREM 3.4 (General existence principle for singular problems I). *Assume* (3.3). *Let there exist a bounded set* $\Omega \subset C^1[0, T]$ *such that*

(i) *for each* $n \in \mathbb{N}$, *the regular problem* (3.6), (3.5) *has a solution* $u_n \in \Omega$,

(ii) *the sequence* $\{f_n(t, u_n(t), u_n'(t))\}$ *is uniformly integrable on* $[0, T]$.

Then

(a) *there exist* $u \in \overline{\Omega}$ *and a subsequence* $\{u_{k_n}\}$ *of* $\{u_n\}$ *such that* $\lim_{n\to\infty} u_{k_n} = u$ *in* $C^1[0,T]$,

(b) *u is a solution of problem* (3.4), (3.5) *if*

$$\lim_{n\to\infty} f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big) = f\big(t, u(t), u'(t)\big)$$

for a.e. $t \in [0,T]$.

PROOF. Since Ω is bounded in $C^1[0,T]$ and $\{u_n\} \subset \Omega$, we have

$$\|u_n\|_\infty \leqslant r, \quad \|u'_n\|_\infty \leqslant r, \quad n \in \mathbb{N}, \tag{3.15}$$

where r is a positive constant. Now (ii) guarantees that for each $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\big|\phi\big(u'_n(t_2)\big) - \phi\big(u'_n(t_1)\big)\big| \leqslant \left|\int_{t_1}^{t_2} \big|f_n\big(t, u_n(t), u'_n(t)\big)\big|\,\mathrm{d}t\right| < \varepsilon$$

for each t_1, $t_2 \in [0,T]$, $|t_1 - t_2| < \delta$ and $n \in \mathbb{N}$. Therefore $\{\phi(u'_n)\}$ is equicontinuous on $[0,T]$, and by virtue of (3.15) and the fact that ϕ is continuous and increasing on $\mathbb{R}$, $\{u'_n\}$ is equicontinuous on $[0,T]$ as well. The Arzelà–Ascoli theorem guarantees the existence of a subsequence $\{u_{k_n}\}$ of $\{u_n\}$ converging in $C^1[0,T]$ to some $u \in \overline{\Omega}$.

Suppose that $\lim_{n\to\infty} f_{k_n}(t, u_{k_n}(t), u'_{k_n}(t)) = f(t, u(t), u'(t))$ for a.e. $t \in [0,T]$. By (ii), $\{f_{k_n}(t, u_{k_n}(t), u'_{k_n}(t))\}$ is uniformly integrable on $[0,T]$. Therefore, by Vitali's convergence theorem, $f(t, u(t), u'(t)) \in L_1[0,T]$ and letting $n \to \infty$ in

$$\phi\big(u'_{k_n}(t)\big) = \phi\big(u'_{k_n}(0)\big) + \int_0^t f_{k_n}\big(s, u_{k_n}(s), u'_{k_n}(s)\big)\,\mathrm{d}s, \quad t \in [0,T],\ n \in \mathbb{N},$$

we arrive at

$$\phi\big(u'(t)\big) = \phi\big(u'(0)\big) + \int_0^t f\big(s, u(s), u'(s)\big)\,\mathrm{d}s, \quad t \in [0,T].$$

Consequently, $\phi(u') \in AC[0,T]$ and u is a solution of (3.4). In addition, since

$$\lim_{n\to\infty} u_{k_n} = u \quad \text{in } C^1[0,T]$$

and α and β are continuous in $C^1[0,T]$, it follows that $\alpha(u) = 0$, $\beta(u) = 0$. Hence u is a solution of problem (3.4), (3.5). □

REMARK 3.5. Let f in (3.4) have singularities only at the value 0 of its space variables and let f_n in (3.6) satisfy $f_n(t,x,y) = f(t,x,y)$ for a.e. $t \in [0,T]$ and all $(x,y) \in \mathcal{D}$, $n \in \mathbb{N}$, $|x| \geqslant \frac{1}{n}$ and $|y| \geqslant \frac{1}{n}$. Then the condition

$$\lim_{n\to\infty} f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big) = f\big(t, u(t), u'(t)\big)$$

for a.e. $t \in [0, T]$ is satisfied if u and u' have a finite number of zeros.

THEOREM 3.6 (General existence principle for singular problems II). *Assume* (3.3). *Let f have singularities only at the value* 0 *of its space variables. Let f_n in equation* (3.6) *satisfy*

$$\begin{cases} \text{for a.e. } t \in [0, T] \text{ and each } x, y \in \mathbb{R} \setminus \{0\}, \\ 0 \leqslant f_n(t, x, y) \leqslant p(|x|, |y|) \quad \text{where } p \in C((0, \infty) \times (0, \infty)). \end{cases} \tag{3.16}$$

Suppose that for each $n \in \mathbb{N}$, the regular problem (3.6), (3.5) *has a solution u_n and there exists a subsequence $\{u_{k_n}\}$ of $\{u_n\}$ converging in $C^1[0, T]$ to some u. Then u is a solution of the singular problem* (3.4), (3.5) *if u and u' have a finite number of zeros and*

$$\lim_{n \to \infty} f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big) = f\big(t, u(t), u'(t)\big) \quad \text{for a.e. } t \in [0, T]. \tag{3.17}$$

PROOF. Assume that (3.17) is true and $0 \leqslant \xi_1 < \xi_2 < \cdots < \xi_m \leqslant T$ are all the zeros of u and u'. Since $\|u_{k_n}\|_\infty \leqslant L$ and $\|u'_{k_n}\|_\infty \leqslant L$ for each $n \in \mathbb{N}$ where L is a positive constant, it follows from (3.16), (3.17),

$$\phi\big(u'_{k_n}(T)\big) - \phi\big(u'_{k_n}(0)\big) = \int_0^T f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big)\,\mathrm{d}t, \quad n \in \mathbb{N},$$

and the Fatou theorem that

$$\int_0^T f\big(t, u(t), u'(t)\big)\,\mathrm{d}t \leqslant \phi(L) - \phi(-L).$$

Hence $f(t, u(t), u'(t)) \in L_1[0, T]$. Set $\xi_0 = 0$ and $\xi_{m+1} = T$. We claim that for all $j \in \{0, 1, \dots, m\}$, $\xi_j < \xi_{j+1}$, the equality

$$\phi\big(u'(t)\big) = \phi\left(u'\left(\frac{\xi_j + \xi_{j+1}}{2}\right)\right) + \int_{\frac{\xi_j+\xi_{j+1}}{2}}^t f\big(s, u(s), u'(s)\big)\,\mathrm{d}s \tag{3.18}$$

is satisfied for $t \in [\xi_j, \xi_{j+1}]$. Indeed, let $j \in \{0, 1, \dots, m\}$ and $\xi_j < \xi_{j+1}$. Let us look at the interval $[\xi_j + \delta, \xi_{j+1} - \delta]$ where $\delta \in (0, \frac{\xi_j+\xi_{j+1}}{2})$. We know that $|u| > 0$ and $|u'| > 0$ on (ξ_j, ξ_{j+1}) and therefore $|u(t)| \geqslant \varepsilon$, $|u'(t)| \geqslant \varepsilon$ for $t \in [\xi_j + \delta, \xi_{j+1} - \delta]$ with a positive constant ε. Hence there exists $n_0 \in \mathbb{N}$ such that $|u_{k_n}(t)| \geqslant \frac{\varepsilon}{2}$, $|u'_{k_n}(t)| \geqslant \frac{\varepsilon}{2}$ for $t \in [\xi_j + \delta, \xi_{j+1} - \delta]$ and $n \geqslant n_0$. This yields (see (3.16))

$$0 \leqslant f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big) \leqslant \max\left\{p(u, v)\colon u, v \in \left[\frac{\varepsilon}{2}, L\right]\right\}$$

for a.e. $t \in [\xi_j + \delta, \xi_{j+1} - \delta]$ and all $n \geqslant n_0$. Letting $n \to \infty$ in

$$\phi\big(u'_{k_n}(t)\big) = \phi\left(u'_{k_n}\left(\frac{\xi_j + \xi_{j+1}}{2}\right)\right) + \int_{\frac{\xi_j+\xi_{j+1}}{2}}^t f_{k_n}\big(s, u_{k_n}(s), u'_{k_n}(s)\big)\,\mathrm{d}s$$

gives (3.18) for $t \in [\xi_j + \delta, \xi_{j+1} - \delta]$ by the Lebesgue dominated convergence theorem. Since $\delta \in (0, \frac{\xi_j + \xi_{j+1}}{2})$ is arbitrary, (3.18) is true on the interval (ξ_j, ξ_{j+1}) and using the fact that $f(t, u(t), u'(t)) \in L_1[0, T]$, we conclude that (3.18) holds also at $t = \xi_j$ and ξ_{j+1}. From (3.18) it follows that $\phi(u') \in AC[0, T]$ and Eq. (3.4) is satisfied for a.e. $t \in [0, T]$. Finally, $\alpha(u_{k_n}) = 0$ and $\beta(u_{k_n}) = 0$ and the continuity of α and β yields $\alpha(u) = 0$ and $\beta(u) = 0$. Hence u is a solution of problem (3.4), (3.5). □

3.3. *Nonlocal singular BVPs*

We consider differential equations of the type

$$\big(\phi(u')\big)' = f(t, u, u') \tag{3.19}$$

where ϕ is an increasing and odd homeomorphism, $\phi(\mathbb{R}) = \mathbb{R}$, f satisfies the Carathéodory conditions on a subset of $[0, T] \times \mathbb{R}^2$ and f may be singular in its space variables.

We also discuss nonlinear nonlocal boundary conditions

$$u(0) = u(T), \quad \max\big\{u(t)\colon 0 \leqslant t \leqslant T\big\} = c, \ c \in \mathbb{R}, \tag{3.20}$$

$$u(0) = u(T) = -\gamma \min\big\{u(t)\colon 0 \leqslant t \leqslant T\big\}, \quad \gamma \in (0, \infty), \tag{3.21}$$

$$\min\big\{u(t)\colon 0 \leqslant t \leqslant T\big\} = 0, \quad \delta(u') = 0, \quad \delta \in \mathcal{B}, \tag{3.22}$$

where $\mathcal{B}$ denotes the set of functionals $\delta : C[0, T] \to \mathbb{R}$ which are

(a) continuous, $\delta(0) = 0$, and

(b) increasing, that is $x, y \in C[0, T]$, $x < y$ on $(0, T) \Rightarrow \delta(x) < \delta(y)$.

EXAMPLE. Let $n \in \mathbb{N}$ and $0 \leqslant a < b \leqslant T$. Then the functionals $\delta_1(x) = x(\frac{T}{2}) + \max\{x(t)\colon 0 \leqslant t \leqslant T\}$, $\delta_2(x) = \int_a^b x^{2n+1}(t)\,\mathrm{d}t$, $\delta_3(x) = \int_0^T \mathrm{e}^{x(t)}\,\mathrm{d}t - T$ belong to the set $\mathcal{B}$. The functionals $\delta_4(x) = x(0)$ and $\delta_5(x) = x(T)$ satisfy condition (a) of $\mathcal{B}$ but do not satisfy condition (b). Hence $\delta_4, \delta_5 \notin \mathcal{B}$.

The boundary conditions (3.20)–(3.22) are special cases of (3.5) where

$$\alpha(x) = x(0) - x(T), \qquad \beta(x) = \max\big\{x(t)\colon 0 \leqslant t \leqslant T\big\} - c \qquad \text{for (3.20)},$$

$$\alpha(x) = x(0) - x(T), \qquad \beta(x) = x(0) + \gamma \min\big\{x(t)\colon 0 \leqslant t \leqslant T\big\} \quad \text{for (3.21)},$$

and

$$\alpha(x) = \min\big\{x(t)\colon 0 \leqslant t \leqslant T\big\}, \qquad \beta(x) = \delta(x') \quad \text{for (3.22)}.$$

The next theorems give sufficient conditions for solvability of the three nonlocal singular problems given above. Their proofs are based on applying general existence principles presented in Theorems 3.2, 3.4 and 3.6. Notice that if $f < 0$ in Eq. (3.19) then the singular points corresponding to the solutions of problem (3.19), (3.20) are of type II and, if $f > 0$, the solutions of problems (3.19), (3.21) and (3.19), (3.22) have singular points of type II.

THEOREM 3.7 [137, Theorem 2.1]. *Suppose* $f \in Car([0,T] \times \mathbb{R} \times (\mathbb{R} \setminus \{0\})$,

$$\begin{cases} -q(x)\big(\omega_1(|y|) + \omega_2(|y|)\big) \leqslant f(t,x,y) \leqslant -a \\ \textit{for a.e. } t \in [0,T] \textit{ and each } (x,y) \in \mathbb{R} \times (\mathbb{R} \setminus \{0\}), \\ \textit{where } a > 0,\ q \in C(\mathbb{R}) \textit{ is positive}, \omega_1 \in C[0,\infty) \textit{ is nonnegative}, \\ \omega_2 \in C(0,\infty) \textit{ is positive and nonincreasing and} \\ \int_0^1 \omega_2\big(\phi^{-1}(s)\big)\,\mathrm{d}s < \infty \end{cases} \tag{3.23}$$

and

$$\int_{d-1}^{d} \frac{\mathrm{d}s}{H^{-1}(\int_s^d q(v)\,\mathrm{d}v)} < \infty \quad \textit{for any } d \in \mathbb{R},$$

where

$$H(x) = \int_0^{\phi(x)} \frac{\phi^{-1}(s)\,\mathrm{d}s}{\omega_1(1+\phi^{-1}(s)) + \omega_2(\phi^{-1}(s))} \quad \textit{for } x \in [0,\infty).$$

Let

$$\mathcal{S} = \left\{c \in \mathbb{R}\colon \lim_{x \to -\infty} \int_x^c \frac{\mathrm{d}s}{H^{-1}(\int_s^c q(v)\mathrm{d}v)} > \frac{T}{2}\right\}.$$

Then problem (3.19), (3.20) *has a solution for each* $c \in \mathcal{S}$.

SKETCH OF PROOF. *Step* 1. *Regularization.*

A sequence of auxiliary regular differential equations $(\phi(u'))' = f_n(t,u,u')$ is constructed where $f_n \in Car([0,T] \times \mathbb{R}^2)$ and

$$f_n(t,x,y) = f(t,x,y) \quad \text{for a.e. } t \in [0,T] \text{ and each } x \in \mathbb{R},\ |y| \geqslant \frac{1}{n},\ n \in \mathbb{N}.$$

Step 2. *Existence of solutions of regular problems* (3.6), (3.20).

Let $c \in \mathcal{S}$. By (3.23), the existence of positive constants S_0 and S_1 (independent of n and λ) is proved such that $\|u\|_\infty < S_0$ and $\|u'\|_\infty < S_1$ for any $\lambda \in [0,1]$, $n \in \mathbb{N}$ and each solution u of the differential equation

$$\big(\phi(u')\big)' = \lambda f_n(t,u,u') \tag{3.24}$$

satisfying the conditions (3.20). Put $\alpha(x) = x(0) - x(T)$ and $\beta(x) = \max\{x(t)\colon 0 \leqslant t \leqslant T\} - c$ for $x \in C^1[0,T]$. Then system (3.10) has a unique solution $(A,B) = (c\frac{1-\mu}{1+\mu}, 0)$

for each $\mu \in [0, 1]$ and therefore all solutions of this system are bounded in $\mathbb{R}^2$. Hence Theorem 3.2 guarantees that for each $n \in \mathbb{N}$, problem (3.6), (3.20) has a solution u_n and $\|u_n\|_\infty < S_0$, $\|u_n'\|_\infty < S_1$.

Step 3. *Properties of solutions of regular problems* (3.6), (3.20).

The sequence $\{u_n\}$ is considered. It is proved that

$$\begin{aligned} &u_n'(t) \geqslant \phi^{-1}\big(a(\xi_n - t)\big) && \text{for } t \in [0, \xi_n], \\ &\big|u_n'(t)\big| \geqslant \phi^{-1}\big(a(t - \xi_n)\big) && \text{for } t \in [\xi_n, T], \end{aligned}$$

where ξ_n is the unique zero of u_n' and $a > 0$ appears in (3.23). Next, it is shown that the sequence $\{f_n(t, u_n(t), u_n'(t))\}$ is uniformly integrable on $[0, T]$. Hence $\{u_n\}$ is bounded in $C^1[0, T]$ and $\{u_n'\}$ is equicontinuous on $[0, T]$ and, by the Arzelà–Ascoli theorem and the compactness principle, we can assume without loss of generality that $\{u_n\}$ converges in $C^1[0, T]$ and $\{\xi_n\}$ converges in $\mathbb{R}$. Let

$$\lim_{n\to\infty} u_n = u \quad \text{and} \quad \lim_{n\to\infty} \xi_n = \xi.$$

Then $u \in C^1[0, T]$ satisfies (3.20),

$$\begin{aligned} &u'(t) \geqslant \phi^{-1}\big(a(\xi - t)\big) && \text{for } t \in [0, \xi], \\ &\big|u'(t)\big| \geqslant \phi^{-1}\big(a(t - \xi)\big) && \text{for } t \in [\xi, T] \end{aligned}$$

and

$$\lim_{n\to\infty} f_n\big(t, u_n(t), u_n'(t)\big) = f\big(t, u(t), u'(t)\big) \quad \text{for a.e. } t \in [0, T].$$

Theorem 3.4 now guarantees that u is a solution of problem (3.19), (3.20). □

EXAMPLE. Let $p > 2$, $\alpha \in [0, p - 2)$ and $\beta \in (0, p - 1)$. Then for any $c \in \mathbb{R}$ there exists a solution of the differential equation

$$\big(|u'|^{p-2}u'\big)' + \big(2 + \sin(tu) + |u|\big)\left(|u'|^\alpha + \frac{1}{|u'|^\beta}\right) = 0$$

satisfying boundary conditions (3.20).

THEOREM 3.8 [138, Theorem 4.1]. *Let* $f \in Car([0,T] \times (\mathbb{R} \setminus \{0\})^2)$. *Let*

$$\begin{cases} a \leqslant f(t,x,y) \leqslant \big(h_1(|x|) + h_2(|x|)\big)\big(\omega_1(\phi(|y|)) + \omega_2(\phi(|y|))\big) \\ \text{for a.e. } t \in [0,T] \text{ and all } (x,y) \in (\mathbb{R} \setminus \{0\})^2, \\ \text{where } a > 0,\ h_1, \omega_1 \in C[0,\infty) \text{ are nonnegative and nondecreasing}, \\ h_2, \omega_2 \in C(0,\infty) \text{ are positive and nonincreasing}, \\ \displaystyle\int_0^1 h_2(s)\,\mathrm{d}s < \infty, \quad \int_0^1 \omega_2(s)\,\mathrm{d}s < \infty, \quad \int_0^\infty \frac{\mathrm{d}s}{\omega_2(s)} = \infty, \end{cases} \tag{3.25}$$

and let

$$\liminf_{x\to\infty} \int_0^x \frac{\mathrm{d}s}{K^{-1}(\frac{T}{2}(h_1(x) + h_2(s)))} > \frac{T}{2}, \tag{3.26}$$

where

$$K(x) = \int_0^{\phi(x)} \frac{\mathrm{d}s}{\omega_1(\phi(1) + s) + \omega_2(s)}, \quad x \in [0,\infty). \tag{3.27}$$

Then there exists a solution of problem (3.19), (3.21) *for each* $\gamma > 0$.

SKETCH OF PROOF. *Step* 1. *Regularization.*

A sequence of approximating differential equations

$$\big(\phi(u')\big)' = f_n(t,u,u')$$

is introduced where $f_n \in Car([0,T] \times \mathbb{R}^2)$ and

$$f_n(t,x,y) = f(t,x,y) \quad \text{for a.e. } t \in [0,T] \text{ and each } |x| \geqslant \frac{1}{n},\ |y| \geqslant \frac{1}{n},\ n \in \mathbb{N}.$$

Step 2. *Existence of solutions of regular problems* (3.6), (3.21).

Let $\gamma > 0$ in (3.21). Using (3.25) and (3.26), the existence of a positive constant P (depending on γ) is proved such that $\|u\|_\infty < PT$ and $\|u'\|_\infty < P$ for each solution u of problem (3.24), (3.21) with $\lambda \in [0,1]$ and $n \in \mathbb{N}$. Put $\alpha(x) = x(0) - x(T)$ and

$$\beta(x) = x(0) + \gamma \min\big\{x(t)\colon 0 \leqslant t \leqslant T\big\} \quad \text{for } x \in C^1[0,T].$$

The system (3.10) has a unique solution $(A,B) = (0,0)$ for each $\mu \in [0,1]$. Hence, by Theorem 3.2 for each $n \in \mathbb{N}$, there exists a solution u_n of problem (3.6), (3.21) and $\|u_n\|_\infty < PT$, $\|u_n'\|_\infty < P$.

Step 3. *Properties of solutions of regular problems* (3.6), (3.21).

The sequence $\{u_n\}$ is considered. From (3.25) it follows that u_n' is increasing on $[0, T]$ and has a unique zero $\xi_n \in (0, T)$ and u_n vanishes exactly at two points t_{1n}, t_{2n}, $0 < t_{1n} < \xi_n < t_{2n} < T$, $u_n > 0$ on $[0, t_{1n}) \cup (t_{2n}, T]$ and $u_n < 0$ on (t_{1n}, t_{2n}). Further, u_n satisfies the inequality

$$|u_n(t)| \geqslant \begin{cases} \dfrac{S|t - t_{1n}|}{\xi_n - t_{1n}} & \text{for } t \in [0, \xi_n], \\[2ex] \dfrac{S|t - t_{2n}|}{t_{2n} - \xi_n} & \text{for } t \in [\xi_n, T], \end{cases}$$

where S is a positive constant and the sequence $\{f_n(t, u_n(t), u_n'(t))\}$ is uniformly integrable on $[0, T]$, which implies that $\{u_n'\}$ is equicontinuous on $[0, T]$. Moreover, there exists a positive constant Δ such that

$$t_{1n} \geqslant \gamma\Delta, \quad \xi_n - t_{1n} > \Delta, \quad t_{2n} - \xi_n > \Delta, \quad T - t_{2n} > \gamma\Delta \quad \text{for } n \in \mathbb{N}.$$

Hence, by the Arzelà–Ascoli theorem, there exists a subsequence $\{u_{k_n}\}$ which converges in $C^1[0, T]$ and let $u = \lim_{n\to\infty} u_{k_n}$. Then u vanishes exactly at two points in $[0, T]$, u' has a unique zero and $\lim_{n\to\infty} f_{k_n}(t, u_{k_n}(t), u_{k_n}'(t)) = f(t, u(t), u'(t))$ for a.e. $t \in [0, T]$. Now Theorem 3.4 guarantees that u is a solution of problem (3.19), (3.21). $\square$

REMARK 3.9. If $\lim_{x\to\infty} h_2(x) < A$ for some $A > 0$ and

$$\liminf_{x\to\infty} \frac{x}{K^{-1}(\frac{T}{2}(h_1(x) + A))} > \frac{T}{2},$$

then condition (3.26) is satisfied.

EXAMPLE. Let $q_j \in L_\infty[0, T]$ be nonnegative $(1 \leqslant j \leqslant 6)$, $q_1(t) \geqslant a > 0$ for a.e. $t \in [0, T]$, $p > 1$, $\beta_1, \beta_2, \beta_3 \in (0, p - 1)$, $\alpha_1 \in (0, p - 1 + \beta_2)$, $\alpha_2, \alpha_3 \in (0, 1)$. Then for each $\gamma > 0$, there exists a solution of the differential equation

$$\left(|u'|^{p-2}u'\right)' = q_1(t) + q_2(t)|u|^{\alpha_1} + \frac{q_3(t)}{|u|^{\alpha_2}} + \frac{q_4(t)}{|u|^{\alpha_3}|u'|^{\beta_1}} + q_5(t)|u'|^{\beta_2} + \frac{q_6(t)}{|u'|^{\beta_3}}$$

satisfying boundary conditions (3.21).

THEOREM 3.10. *Suppose* $f \in Car([0,T] \times (0,\infty) \times (\mathbb{R} \setminus \{0\}))$ *and the following conditions are satisfied*:

$$\begin{cases} \varphi(t) \leqslant f(t,x,y) \leqslant \big(h_1(x) + h_2(x)\big)\big[\omega_1\big(\phi(|y|)\big) + \omega_2\big(\phi(|y|)\big)\big] \\ \text{for a.e. } t \in [0,T] \text{ and each } (x,y) \in (0,\infty) \times (\mathbb{R} \setminus \{0\}), \\ \text{where } \varphi \in L_\infty[0,T] \text{ is positive}, \\ h_1, \omega_1 \in C[0,\infty) \text{ are positive and nondecreasing}, \\ h_2, \omega_2 \in C(0,\infty) \text{ are positive and nonincreasing}, \\ \displaystyle\int_0^1 h_2(s)\,\mathrm{d}s < \infty \end{cases} \tag{3.28}$$

and

$$\liminf_{x\to\infty} \frac{V(x)}{H(Tx)} > 1 \tag{3.29}$$

where

$$V(x) = \int_0^{\phi(x)} \frac{\phi^{-1}(s)\,\mathrm{d}s}{\omega_1(s+1) + \omega_2(s)},$$

$$H(x) = \int_0^x \big(h_1(s+1) + h_2(s)\big)\,\mathrm{d}s \quad \text{for } x \in [0,\infty).$$

Then for each $\delta \in \mathcal{B}$, *problem* (3.19), (3.22) *has a solution.*

SKETCH OF PROOF. *Step* 1. *Regularization.*

A sequence of auxiliary regular differential equations $(\phi(u'))' = f_n(t,u,u')$ is constructed with $f_n \in Car([0,T] \times \mathbb{R}^2)$ satisfying

$$f_n(t,x,y) = f(t,x,y) \quad \text{for a.e. } t \in [0,T] \text{ and each } x \geqslant \frac{1}{n},\ |y| \geqslant \frac{1}{n},\ n \in \mathbb{N}.$$

Step 2. *Existence of solutions of regular problems* (3.6), (3.22).

Fix $\delta \in \mathcal{B}$. From (3.28), (3.29) and from the properties of δ we obtain the existence of positive constants M_0 and M_1 such that $\|u\|_\infty < M_0$, $\|u'\|_\infty < M_1$ for each solution u of problem (3.24), (3.22) with $\lambda \in [0,1]$ and $n \in \mathbb{N}$. Set $\alpha(x) = \min\{x(t)\colon\ 0 \leqslant t \leqslant T\}$ and $\beta(x) = \delta(x')$ for $x \in C^1[0,T]$. Then system (3.10) has a unique solution $(A,B) = (0,0)$ for each $\mu \in [0,1]$. Therefore, by Theorem 3.2, for each $n \in \mathbb{N}$ there exists a solution u_n of problem (3.6), (3.22) and $\|u_n\|_\infty < M_0$, $\|u'\|_\infty < M_1$.

Step 3. *Properties of solutions of regular problems* (3.6), (3.22).

By Step 2, $\{u_n\}$ is bounded in $C^1[0,T]$ and from (3.28) it follows that $\{u_n'\}$ is equicontinuous on $[0,T]$. The assumption (3.28) and the properties of δ show that u_n has a unique zero ξ_n, $\xi_n \in (0,T)$, u_n' is increasing on $[0,T]$, $u_n'(\xi_n) = 0$ and

$$\left|u_n'(t)\right| \geqslant \left|\int_{\xi_n}^t \varphi(s)\,\mathrm{d}s\right|, \qquad u_n(t) \geqslant \int_{\xi_n}^t (t-s)\varphi(s)\,\mathrm{d}s \tag{3.30}$$

for $t \in [0,T]$. According to the Arzelà–Ascoli theorem, there exists a subsequence $\{u_{k_n}\}$ converging in $C^1[0,T]$ to some u and from (3.30) we see that u and u' vanish at a unique point. Since

$$\lim_{n\to\infty} f_{k_n}\bigl(t, u_{k_n}(t), u_{k_n}'(t)\bigr) = f\bigl(t, u(t), u'(t)\bigr) \quad \text{for a.e. } t \in [0,T],$$

Theorem 3.6 gives that u is a solution of problem (3.19), (3.22). □

REMARK 3.11. Problem (3.19), (3.22) was investigated in [140]. The conditions for the solvability of this problem are stronger there than those in Theorem 3.10. This is due to the fact that [140] uses the Vitali convergence theorem in limit processes whereas Theorem 3.10 is proved by Theorem 3.6.

EXAMPLE. Let $\varphi \in L_\infty[0,T]$ be positive, $p > 1$, $c_j > 0$ $(1 \leqslant j \leqslant 4)$, $\beta \in (0,1)$, $\alpha, \gamma, \delta, \lambda \in (0,\infty)$ and $\alpha + \gamma < p - 1$. Then for each $\delta \in \mathcal{B}$, the differential equation

$$\bigl(|u'|^{p-2}u'\bigr)' = \varphi(t)\left(1 + c_1 u^\alpha + \frac{c_2}{u^\beta}\right)\left(1 + c_3|u'|^\gamma + \frac{c_4}{|u'|^\lambda}\right)$$

has a solution u satisfying boundary conditions (3.22).

3.4. *Historical and bibliographical notes*

The general existence principles presented in Theorems 3.2 and 3.4 are special cases of the principles stated by Agarwal, O'Regan and Staněk in [16] for a class of second-order functional differential equations. Some general existence principles for second-order regular differential equations with the ϕ-Laplacian and Dirichlet or mixed boundary data have been established using the nonlinear alternative of Leray–Schauder type by O'Regan [109].

Second-order differential equations with the p-Laplacian and the ϕ-Laplacian occur in the study of the p-Laplace equations [91], general diffusion theory [22,40], non-Newtonian fluid theory [81] and the turbulent flow of a polytropic gas in a porous medium [60,36].

In recent years problems for $p(t)$-Laplacian equations have been studied (e.g., [63,64]). The $p(t)$-Laplacian is defined by $u \to (|u'|^{p(t)-2}u')'$ where $p \in C[0,T]$ and $p > 1$ on $[0,T]$. The $p(t)$-Laplacian is a generalization of the p-Laplacian.

4. Singular Dirichlet BVPs with ϕ-Laplacian

Motivated by various significant applications to non-Newtonian fluid theory, diffusion of flows in porous media, nonlinear elasticity and theory of capillary surfaces (see [22,60, 112], and Section 3.4), several authors have proposed the study of equations $(\phi_p(u'))' + f(t,u,u') = 0$ with the p-Laplacian $(\phi_p(u'))'$, where $p \in (1,\infty)$ and $\phi_p(y) = |y|^{p-2}y$ for $y \in \mathbb{R}$. Usually the p-Laplacian is replaced by its abstract and more general version, which leads to clearer exposition and better understanding of the methods that are employed to derive existence results. Therefore, similarly to Section 3, we will work with a ϕ-Laplacian which satisfies (3.3), i.e. ϕ is an increasing homeomorphism with $\phi(\mathbb{R}) = \mathbb{R}$.

We will consider a singular Dirichlet problem of the form

$$\big(\phi(u')\big)' + f(t,u,u') = 0, \quad u(0) = u(T) = 0 \tag{4.1}$$

and its special cases, in particular, a problem of the form

$$u'' + f(t,u,u') = 0, \quad u(0) = u(T) = 0, \tag{4.2}$$

where $\phi(y) = y$ on $\mathbb{R}$.

We will investigate problems (4.1) and (4.2) on the set $[0,T] \times \mathcal{A}$. In general, the function f depends on a time variable $t \in [0,T]$ and on two space variables x and y, where $(x,y) \in \mathcal{A}$ and $\mathcal{A}$ is a closed subset of $\mathbb{R}^2$ or $\mathcal{A} = \mathbb{R}^2$.

We assume that problems (4.1) and (4.2) are singular, which means, by Section 1, that f does not satisfy the Carathéodory conditions on $[0,T] \times \mathcal{A}$. In what follows, the types of singularities of f will be exactly specified for each problem under consideration.

In accordance with Section 1 we define:

DEFINITION 4.1. A function $u : [0,T] \to \mathbb{R}$ with $\phi(u') \in AC[0,T]$ is *a solution of problem* (4.1) if u satisfies $(\phi(u'(t)))' + f(t,u(t),u'(t)) = 0$ a.e. on $[0,T]$ and fulfills the boundary conditions $u(0) = u(T) = 0$.

A function $u \in C[0,T]$ is *a w-solution of problem* (4.1) if there exists a finite number of singular points $t_\nu \in [0,T]$, $\nu = 1,\dots,r$, such that if we denote $J = [0,T] \setminus \{t_\nu\}_{\nu=1}^r$, then $\phi(u') \in AC_{loc}(J)$, u satisfies $(\phi(u'(t)))' + f(t,u(t),u'(t)) = 0$ a.e. on $[0,T]$ and fulfills the boundary conditions $u(0) = u(T) = 0$.

Note that the condition $\phi(u') \in AC[0,T]$ implies $u \in C^1[0,T]$ and the condition $\phi(u') \in AC_{loc}(J)$ implies $u \in C^1(J)$. We will mention some papers where f is supposed to be continuous on $(0,T) \times \mathbb{R}^2$ and can have only time singularities at $t = 0$ and $t = T$. Then any solution (any w-solution) u of (4.1) moreover satisfies $\phi(u') \in C^1(0,T)$. If we investigate the solvability of problem (4.1) or (4.2) on the set $[0,T] \times \mathcal{A}$ and $\mathcal{A} \neq \mathbb{R}^2$, we impose on its solution u in addition the condition

$$\big(u(t), u'(t)\big) \in \mathcal{A} \quad \text{for } t \in [0,T]. \tag{4.3}$$

If u is a w-solution, then one requires it to satisfy (4.3) for $t \in J$ only.

In some cases (see, e.g., (4.9)) f does not depend on y. Then we work with a set $\mathcal{A}$ which is a closed subset of $\mathbb{R}$ or $\mathcal{A} = \mathbb{R}$ and condition (4.3) has the form $u(t) \in \mathcal{A}$ for $t \in [0, T]$.

REMARK 4.2. We will carry out the investigation of the singular problem (4.1) in the spirit of the existence principles presented in Sections 1 and 3:

- the singular problem is approximated by a sequence of solvable regular problems;
- a sequence $\{u_n\}$ of approximate solutions is generated;
- a convergence of a suitable subsequence $\{u_{k_n}\}$ is investigated;
- the type of this convergence determines the properties of its limit u and, among others, determines whether u is a w-solution or a solution of the original singular problem.

There are more possibilities how to construct an approximating sequence of regular problems. Their choice depends on the type of singularities of the nonlinearity f in (4.1) (time, space), on the type of singular points corresponding to a solution (w-solution) of (4.1) (type I, type II), on the type of results desired (existence of a solution, a positive solution, a w-solution, uniqueness), and so on. A common idea is that approximate functions f_n have no singularities, $f_n \neq f$ on neighbourhoods U_n of singular points of f, $f_n = f$ elsewhere, and $\lim_{n\to\infty} \operatorname{meas}(U_n) = 0$.

Having such a sequence of $\{f_n\}$ we study problems

$$\big(\phi(u')\big)' + f_n(t, u, u') = 0, \quad u(0) = u(T) = \varepsilon_n,\ n \in \mathbb{N}, \tag{4.4}$$

where $\varepsilon_n \in \mathbb{R}$, $\lim_{n\to\infty} \varepsilon_n = 0$. In some proofs, one simply puts $\varepsilon_n = 0$ for $n \in \mathbb{N}$.

Solvability of (4.4) can be investigated by means of various methods which have been developed for regular Dirichlet problems (fixed point theorems, topological degree arguments, the topological transversality method, variational methods, lower and upper functions, the Fredholm nonlinear alternative, etc.). See also Section 3. Using one of the above methods we generate a sequence of approximate solutions $\{u_n\}$ of (4.4). The crucial information which enables us to realize the limit process concerns a priori estimates of the approximate solutions u_n.

4.1. *Method of lower and upper functions*

It is well known that for regular second order boundary value problems *the lower and upper functions method* is a profitable instrument for proofs of their solvability and for a priori estimates of their solutions. See, e.g., [47–49,93,94,114,124,146]. Hence, it seems to be a good idea to extend this method to the singular problem (4.1). In literature there are several definitions of lower and upper functions for regular boundary value problems. (Note that in some papers they are called lower and upper solutions.) Here we will use the following definition which is the same both for regular problems with $f \in Car([0, T] \times \mathbb{R}^2)$ and for singular ones with $f \in Car((0, T) \times \mathbb{R}^2)$ having time singularities at $t = 0$ and $t = T$.

DEFINITION 4.3. A function $\sigma : [0, T] \to \mathbb{R}$ with $\phi(\sigma') \in AC[0, T]$ is called *a lower function of* (4.1) if σ satisfies

$$\big(\phi\big(\sigma'(t)\big)\big)' + f\big(t, \sigma(t), \sigma'(t)\big) \geqslant 0 \quad \text{for a.e. } t \in [0, T] \tag{4.5}$$

and

$$\sigma(0) \leqslant 0, \quad \sigma(T) \leqslant 0. \tag{4.6}$$

If the inequalities in (4.5) and (4.6) are reversed, then σ is called *an upper function of* (4.1).

For the special case (4.2) we admit a more general definition.

DEFINITION 4.4. A function $\sigma \in C[0, T]$ is called *a lower function of* (4.2) if there exists a finite set $\Sigma \subset (0, T)$ such that $\sigma \in AC^1_{loc}([0, T] \setminus \Sigma)$, $\sigma'(\tau+)$, $\sigma'(\tau-) \in \mathbb{R}$ for each $\tau \in \Sigma$,

$$\sigma''(t) + f\big(t, \sigma(t), \sigma'(t)\big) \geqslant 0 \quad \text{for a.e. } t \in [0, T], \tag{4.7}$$

$$\sigma(0) \leqslant 0, \quad \sigma(T) \leqslant 0, \quad \sigma'(\tau-) < \sigma'(\tau+) \quad \text{for each } \tau \in \Sigma. \tag{4.8}$$

If the inequalities in (4.7) and (4.8) are reversed, then σ is called *an upper function of* (4.2).

REMARK 4.5. (i) If, moreover, f is continuous on $(0, T) \times \mathbb{R}^2$, then a lower (upper) function σ of (4.1) is supposed to satisfy $\phi(\sigma') \in C^1(0, T)$ and a lower (upper) function of (4.2) belongs also to $C^2(0, T)$.

(ii) If the boundary conditions in (4.1) or in (4.2) are replaced by inhomogeneous ones, i.e. they have the form

$$u(0) = a, \quad u(T) = b$$

for some $a, b \in \mathbb{R}$, then the corresponding boundary inequalities in (4.6) or in (4.8) are modified to

$$\sigma(0) \leqslant a, \quad \sigma(T) \leqslant b.$$

We present straightforward extensions of the classical lower and upper functions method to a singular problem with the p-Laplacian

$$\big(\phi_p(u')\big)' + f(t, u) = 0, \quad u(0) = a, \quad u(T) = b, \tag{4.9}$$

where

$$\begin{cases} \phi_p(y) = |y|^{p-2}y, \ p > 1, \ a, b \in \mathbb{R}, \ f \in Car\big((0, T) \times \mathbb{R}\big), \\ f \text{ can have time singularities at } t = 0 \text{ and } t = T. \end{cases} \tag{4.10}$$

Recall that f has time singularities at $t = 0$ and $t = T$ if there exist $x, y \in \mathbb{R}$ such that

$$\int_0^{\varepsilon} \big|f(t,x,y)\big|\,\mathrm{d}t = \infty, \qquad \int_{T-\varepsilon}^{T} \big|f(t,x,y)\big|\,\mathrm{d}t = \infty$$

for each sufficiently small $\varepsilon > 0$.

Making use of ideas of the papers [100] by Lomtatidze and Torres and [80] by Habets and Zanolin, one can prove the following result for the special case of (4.9) with $p = 2$.

THEOREM 4.6. *Let $p = 2$ and* (4.10) *hold. Let σ_1 and σ_2 be a lower and an upper function for problem* (4.9) *and $\sigma_1 \leqslant \sigma_2$ on* $[0, T]$. *Assume also that there is a function $h \in L_1(I)$ on each compact interval $I \subset (0, T)$ such that*

$$\big|f(t,x)\big| \leqslant h(t) \quad \textit{for a.e. } t \in (0,T) \textit{ and each } x \in \big[\sigma_1(t), \sigma_2(t)\big],$$

and

$$\int_0^T t(T-t)h(t)\,\mathrm{d}t < \infty.$$

Then problem (4.9) *has a w-solution $u \in C[0,T] \cap AC^1_{loc}(0,T)$ such that*

$$\sigma_1(t) \leqslant u(t) \leqslant \sigma_2(t) \quad \textit{for } t \in [0,T]. \tag{4.11}$$

If for a.e. $t \in (0,T)$ the function $f(t,x)$ is nonincreasing in x, then the w-solution is unique. If $h \in L_1[0,T]$, then u belongs to $AC^1[0,T]$, i.e. u is a solution of (4.9).

Theorem 4.6 can be proved by means of the Schauder fixed point theorem which is applied to the operator $\mathcal{T} : C[0,T] \to C[0,T]$, where

$$(\mathcal{T}u)(t) = a + \frac{t}{T}(b-a) + \int_0^T G(t,s) f^*\big(s, u(s)\big)\,\mathrm{d}s.$$

Here G is the Green function of the problem $-u'' = 0$, $u(0) = u(T) = 0$ and f^* is given by

$$f^*(t,x) = \begin{cases} f\big(t, \sigma_1(t)\big) & \text{if } x < \sigma_1(t), \\ f(t,x) & \text{if } \sigma_1(t) \leqslant x \leqslant \sigma_2(t), \\ f\big(t, \sigma_2(t)\big) & \text{if } x > \sigma_2(t) \end{cases}$$

for a.e. $t \in [0,T]$ and each $x \in \mathbb{R}$.

REMARK 4.7. By virtue of (4.11) we can investigate problem (4.9) on $[0,T] \times \mathcal{A}_t$, where $\mathcal{A}_t = [\sigma_1(t), \sigma_2(t)]$ for $t \in [0,T]$. Therefore, in Theorem 4.6, instead of $f \in Car((0,T) \times \mathbb{R})$ it is sufficient to assume $f \in Car((0,T) \times A_t)$.

Jiang in [86] dealt with problem (4.9) under the assumption (4.10) and, in addition,

$$f \in C\big((0,T)\times\mathbb{R}\big). \tag{4.12}$$

He modified Theorem 4.6 for $p \neq 2$.

THEOREM 4.8. *Let* (4.10) *and* (4.12) *hold. Let* σ_1 *and* σ_2 *be a lower and an upper function for problem* (4.9) *and* $\sigma_1 \leqslant \sigma_2$ *on* $[0,T]$. *Assume also that there is a function* $h \in C(0,T)$ *such that*

$$\big|f(t,x)\big| \leqslant h(t) \quad \textit{for } t \in (0,T),\ x \in \big[\sigma_1(t),\sigma_2(t)\big],$$

and that there exist $\mu, \nu \in [0, p-1)$ *such that*

$$\int_0^T t^{\mu}(T-t)^{\nu}h(t)\,\mathrm{d}t < \infty. \tag{4.13}$$

Then problem (4.9) *has a w-solution* $u \in C[0,T]$ *satisfying* $\phi_p(u') \in C^1(0,T)$ *and* (4.11).

In contrast to $p = 2$, there is no Green function for $p \neq 2$, which makes the proof of Theorem 4.8 more difficult and complicated than that for $p = 2$.

REMARK 4.9. Motivated by physical and technical problems, there is a lot of papers studying problems *with both time and space singularities*. If such a problem has a singularity at $x = 0$, one often searches for solutions (w-solutions) which are positive on $(0,T)$. Although they vanish at 0 and T, they are still called *positive solutions* (*positive w-solutions*) in literature. In this case, problems (4.1) and (4.2) are investigated on the set $[0,T]\times\mathcal{A}$, where $\mathcal{A} = [0,\infty)\times\mathbb{R}$, and f in (4.1) or (4.2) is supposed to satisfy $f \in Car((0,T)\times\mathcal{D})$, where $\mathcal{D} = (0,\infty)\times\mathbb{R}$ (or more specifically f is supposed to be continuous on $(0,T)\times\mathcal{D}$). In this case lower and upper functions have to be positive on $(0,T)$ and consequently a lower function σ_1 has to satisfy $\sigma_1(0) = \sigma_1(T) = 0$.

Having in mind Remarks 4.7 and 4.9 we will search for positive w-solutions of a singular problem

$$u'' + f(t,u) = 0, \quad u(0) = u(T) = 0, \tag{4.14}$$

where

$$\begin{cases} f \in Car\big((0,T)\times(0,\infty)\big) \text{ can have} \\ \text{time singularities at } t = 0,\ t = T \text{ and a space singularity at } x = 0. \end{cases} \tag{4.15}$$

Recall that f has a space singularity at $x = 0$ if

$$\limsup_{x\to 0+}\big|f(t,x)\big| = \infty \quad \text{for a.e. } t \in [0,T].$$

Let us present a simple application of Theorem 4.6 in the spirit of Habets and Zanolin [80].

THEOREM 4.10. *Let a function f be positive and satisfy* (4.15). *Assume that for a.e. $t \in (0,T)$ the function $f(t,x)$ is nonincreasing in x. Suppose that there exists a lower function σ_1 of problem* (4.14) *such that $\sigma_1 > 0$ on $(0,T)$ and*

$$\int_0^T f\big(s,\sigma_1(s)\big)\,\mathrm{d}s < \infty.$$

Then problem (4.14) *has a unique positive solution $u \in AC^1[0,T]$ such that $\sigma_1 \leqslant u$ on $[0,T]$.*

Theorem 4.10 follows from Theorem 4.6 and Remark 4.7 if we put $h(t) = f(t,\sigma_1(t))$ and

$$\sigma_2(t) = \int_0^T G(t,s) f(s,k)\,\mathrm{d}s + k,$$

where $k = \max\{\sigma_1(t)\colon t \in [0,T]\}$ and G is the Green function of the problem

$$-u'' = 0, \quad u(0) = u(T) = 0.$$

The next result can be viewed as a corollary of [100, Theorem 1.1], where Lomtatidze and Torres studied an equation including an additional term $g(t,u)u'$.

THEOREM 4.11. *Let* (4.15) *hold. Let σ_1 and σ_2 be a lower and an upper function of problem* (4.14) *and*

$$\sigma_2(0) > 0, \quad \sigma_2(T) > 0, \quad 0 < \sigma_1 \leqslant \sigma_2 \quad \text{on } (0,T).$$

Let, moreover, for every $0 < \eta < \min\{\sigma_2(t)\colon t \in [0,T]\}$ there exist $h_\eta \in C(0,T)$ such that

$$\big|f(t,x)\big| \leqslant h_\eta(t) \quad \text{for } t \in (0,T) \text{ and all } x \in \big[\sigma_{1\eta}(t), \sigma_2(t)\big],$$

where $\sigma_{1\eta}(t) = \max\{\eta, \sigma_1(t)\}$ and

$$\int_0^T t(T-t) h_\eta(t)\,\mathrm{d}t < \infty.$$

Then problem (4.14) *has a positive w-solution $u \in C[0,T] \cap AC^1_{loc}(0,T)$ such that*

$$\sigma_1(t) \leqslant u(t) \leqslant \sigma_2(t) \quad \text{for } t \in [0,T].$$

SKETCH OF THE PROOF. *Step* 1. *Construction of auxiliary intervals.*

A decreasing sequence $\{a_n\} \subset (0, T)$ and an increasing sequence $\{b_n\} \subset (0, T)$ are constructed such that, among other, $\lim_{n\to\infty} a_n = 0$, $\lim_{n\to\infty} b_n = T$.

Step 2. *Construction of auxiliary regular problems.*

For $t \in [0, T]$, $x \in \mathbb{R}$, $n \in \mathbb{N}$, functions χ_n, α_n, β, f_n are given by

$$\chi_n(x) = \begin{cases} \sigma_1(a_n) & \text{if } x < \sigma_1(a_n), \\ x & \text{if } x \geqslant \sigma_1(a_n), \end{cases}$$

$$\alpha_n(t) = \begin{cases} \sigma_1(a_n) & \text{if } 0 \leqslant t \leqslant a_n, \\ \sigma_1(t) & \text{if } a_n \leqslant t \leqslant b_n, \\ \sigma_1(b_n) & \text{if } b_n \leqslant t \leqslant T, \end{cases} \qquad \beta(t) = \begin{cases} v_1(t) & \text{if } 0 \leqslant t \leqslant a_1, \\ \sigma_2(t) & \text{if } a_1 \leqslant t \leqslant b_1, \\ v_2(t) & \text{if } b_1 \leqslant t \leqslant T, \end{cases}$$

$$f_n(t, x) = \begin{cases} \frac{1}{2}\big[f\big(t, \chi_n(x)\big) + \big|f\big(t, \chi_n(x)\big)\big|\big] & \text{if } t \in (0, a_n] \cup [b_n, T), \\ f\big(t, \chi_n(x)\big) & \text{if } t \in (a_n, b_n), \end{cases}$$

where v_1 and v_2 are solutions of some auxiliary linear Dirichlet problems.

Step 3. *Convergence of the sequence of approximating solutions.*

Solvability of a sequence of regular problems

$$u'' + f_n(t, u) = 0, \quad u(0) = \sigma_1(a_n), \quad u(T) = \sigma_1(b_n), \quad n \in \mathbb{N}, \tag{4.16}$$

is investigated. The functions α_1 and β are a lower and an upper function of (4.16) with $n = 1$, and hence, by Theorem 4.6, there is a w-solution u_1 of (4.16) with $n = 1$ such that $\alpha_1 \leqslant u_1 \leqslant \beta$ on $[0, T]$. Further, α_2 and u_1 are a lower and an upper function of (4.16) with $n = 2$, and so Theorem 4.6 guarantees the existence of a w-solution u_2 of (4.16) with $n = 2$ such that $\alpha_2 \leqslant u_2 \leqslant u_1$ on $[0, T]$. In this way a sequence of w-solutions is obtained and then a limit process is applied. □

At the end of this subsection we will show another existence assertion in terms of the lower and upper functions for a problem with the p-Laplacian of the form

$$\big(\phi_p(u')\big)' + \psi(t)g(t, u) = 0, \quad u(0) = u(1) = 0, \tag{4.17}$$

where $\phi_p(y) = |y|^{p-2}y$, $p > 1$. Here we assume that

$$\begin{cases} \psi : (0, 1) \to (0, \infty) \text{ is continuous} \\ \text{and can have time singularities at } t = 0 \text{ and } t = 1, \end{cases} \tag{4.18}$$

$$\begin{cases} g : [0, 1] \times (0, \infty) \to \mathbb{R} \text{ is continuous} \\ \text{and can have a space singularity at } x = 0. \end{cases} \tag{4.19}$$

In this setting, using the paper by Agarwal, Lü and O'Regan [2], we offer the following result about the existence of positive w-solutions of (4.17).

THEOREM 4.12. *Let* (4.18) *and* (4.19) *hold. Assume that the following conditions are satisfied*:

$$\begin{cases} \{\rho_n\} \textit{ is a nonincreasing sequence of real numbers}, \\ \lim\limits_{n\to\infty} \rho_n = 0 \textit{ and } n_0 \in \mathbb{N},\ n_0 \geqslant 3 \textit{ being fixed}, \end{cases} \tag{4.20}$$

$$\max\left\{\int_0^{1/2} \phi_p^{-1}\left(\int_s^{1/2} \psi(t)\,\mathrm{d}t\right)\mathrm{d}s, \int_{1/2}^1 \phi_p^{-1}\left(\int_{1/2}^s \psi(t)\,\mathrm{d}t\right)\mathrm{d}s\right\} \\ = b_0 < \infty \tag{4.21}$$

and

$$\psi(t)g(t,\rho_n) \geqslant 0 \quad \textit{for } t \in \left[\frac{1}{2^{n+1}}, 1\right), \quad n \geqslant n_0.$$

Further assume that σ_1 *and* σ_2 *are a lower and an upper function of problem* (4.17) *with* $\sigma_1 > 0$ *on* $(0,1)$, $\max\{\rho_{n_0}, \sigma_1(t)\} \leqslant \sigma_2(t)$ *for* $t \in [0,1]$ *and*

$$\bigl(\phi_p\bigl(\sigma_2'(t)\bigr)\bigr)' + \psi(t)g\left(\frac{1}{2^{n_0+1}}, \sigma_2(t)\right) \leqslant 0 \quad \textit{for } t \in \left(0, \frac{1}{2^{n_0+1}}\right).$$

Then problem (4.17) *has a positive w-solution* $u \in C[0,1]$ *with* $\phi_p(u') \in C^1(0,1)$ *and*

$$\sigma_1(t) \leqslant u(t) \leqslant \sigma_2(t) \quad \textit{for } t \in [0,1].$$

In Section 4.3 we will show how lower and upper functions for regular problems can be applied to get not only a w-solution but also a solution of a given singular problem (see Theorem 4.18).

4.2. *Positive nonlinearities*

Many papers studying problem (4.1) or (4.2) with a space singularity at $x = 0$ concern the case that the nonlinearity f is positive. Such problems are referred to as *positone* ones in literature, see [10,11,135]. The positivity of f implies that each solution is concave and hence positive on $(0,T)$, and if, moreover, f has a space singularity at $x = 0$ but not at y, then each solution has only two corresponding singular points 0, T which are of type I. This makes the study of such problems easier than of those having sign-changing f or space singularities at y.

First we will discuss mixed singularities at t and x. In Section 1.1 we have presented problem (1.3), (1.4) the solvability of which was investigated by Taliaferro [141]. This problem has mixed singularities: the time ones at $t = 0$ and $t = 1$ as well as the space one at $x = 0$. Among many papers generalizing Taliaferro's existence results we choose the paper by Tineo [142] devoted to the existence of positive solutions or w-solutions to a singular problem

$$u'' + f(t, u, u') = 0, \quad u(0) = u(1) = 0, \tag{4.22}$$

where

$$\begin{cases} f : (0, 1) \times (0, \infty) \times \mathbb{R} \to (0, \infty) \text{ is continuous and can have} \\ \text{time singularities at } t = 0,\ t = 1 \text{ and a space singularity at } x = 0. \end{cases} \tag{4.23}$$

THEOREM 4.13 [142, Theorem 0.1]. *Let* (4.23) *hold. Suppose that there are continuous functions* $\varphi : (0, 1) \to (0, \infty)$, $\psi : (0, 1) \to [0, \infty)$ *and* $g : (0, \infty) \to (0, \infty)$ *such that* g *is decreasing and*

$$f(t, x, y) \leqslant \varphi(t)g(x) + \psi(t)|y| \quad \textit{for } t \in (0, 1),\ x \in (0, \infty),\ y \in \mathbb{R},$$

$$\int_0^1 t(1-t)\varphi(t)\,\mathrm{d}t < \infty, \qquad \int_0^1 \psi(t)\,\mathrm{d}t < \infty.$$

Assume further that for each constant $M > 0$ *there exists a continuous function* $\varepsilon_M : (0, 1) \to (0, \infty)$ *such that*

$$\varepsilon_M(t) \leqslant f(t, x, y) \quad \textit{for } t \in (0, 1),\ x \in (0, M],\ y \in \mathbb{R}.$$

Then problem (4.22) *has a positive w-solution* $u \in C[0, 1] \cap C^2(0, 1)$. *If, moreover,*

$$\int_0^1 g\big(kt(1-t)\big)\varphi(t)\,\mathrm{d}t < \infty \quad \textit{for all } k > 0,$$

then u *belongs to* $AC^1[0, 1]$, *which means that* u *is a solution of* (4.22).

The proof of Theorem 4.13 proceeds according to Remark 4.2. Solvability of auxiliary regular problems is obtained by the Leray–Schauder degree argument and the limit process is guaranteed by means of a priori estimates of the approximate solutions.

EXAMPLE. Let $\alpha, \beta \in (0, 2)$, $k, \lambda \in (0, \infty)$, $\varepsilon \in C(0, 1)$, $\varepsilon > 0$ on $(0, 1)$. By Theorem 4.13 the problem

$$u'' + \frac{1}{t^\alpha(1-t)^\beta u^\lambda} + t^k|u'| + \varepsilon(t) = 0, \quad u(0) = u(1) = 0$$

has a positive w-solution $u \in C[0, 1] \cap C^2(0, 1)$. If $\alpha + \lambda, \beta + \lambda \in (0, 1)$ then, moreover, $u \in C^1[0, 1]$. Hence u is a solution.

Let us turn back to problem (4.14) with f satisfying (4.15). Wang in [148] considered f which can have at most linear growth in x. He illustrated his result by functions

$$f(t,x)=\frac{1}{t^{\alpha}x^{\beta}}\quad \text{with } \alpha\in(1,2),\ \beta>0$$

or

$$f(t,x)=\delta x\exp\left(\frac{1}{x}\right)\quad \text{with a sufficiently small } \delta>0.$$

For f which is moreover continuous on $(0,T)\times(0,\infty)$, Agarwal and O'Regan [3,4,11] proved the existence of a positive w-solution of (4.14) with f increasing in x for large x. An example of such f is

$$f(t,x)=\delta\left(\frac{1}{x^{\alpha}}+x^{\beta}+1\right),\quad \alpha,\beta,\delta\in(0,\infty).$$

If f has sublinear growth in x (i.e. $\beta\in(0,1)$), then (4.14) has a positive w-solution for each $\delta>0$. If f has linear or superlinear growth in x (i.e. $\beta=1$ or $\beta\in(1,\infty)$), then (4.14) has a positive w-solution for any sufficiently small $\delta>0$. A formula for an upper bound of δ is also given.

Now let us consider space singularities at x and y. We will present conditions ensuring solvability of problems with singularities in space variables x and y and with singular points both of type I and of type II. The main difficulty in the study of singular points of type II is the fact that their location in $[0,T]$ is not known. This is the reason why in mathematical literature there are only few papers concerning solvability of such problems and no results about w-solutions are known.

The first existence result in this direction was reached by Staněk [135] in 2001. The following theorem can be viewed as a corollary of [135, Theorem 1].

For a fixed $A>0$ we consider a singular problem

$$u''+\mu f(t,u,u')=0,\quad u(0)=u(T)=0,\tag{4.24}$$

with a positive real parameter μ, where

$$\begin{cases} f \text{ is continuous on } \mathcal{D}_A=[0,T]\times(0,A)\times\left[-\frac{2A}{T},0\right)\cup\left(0,\frac{2A}{T}\right] \\ \text{and can have space singularities at } x=0, x=A, y=0. \end{cases}\tag{4.25}$$

Sufficient conditions on μ and f for the solvability of (4.24) in the set $[0,T]\times\mathcal{A}$, where $\mathcal{A}=[0,A]\times[-\frac{2A}{T},\frac{2A}{T}]$, are given in the next theorem.

THEOREM 4.14. *Let* (4.25) *hold. Suppose that there exists* $\delta>0$ *such that* f *satisfies*

$$\delta\leqslant f(t,x,y)\leqslant g(x)\omega\big(|y|\big)\quad \text{on } \mathcal{D}_A,$$

where $\omega \geqslant \delta$ *is continuous on* $(0, \frac{2A}{T}]$ *and* $g \in C(0, A) \cap L_1[0, A]$. *Let*

$$\mu_T = \left(\int_0^{2A/T} \frac{y}{\omega(y)}\,\mathrm{d}y\right)\left(\int_0^A g(x)\,\mathrm{d}x\right)^{-1}.$$

Then for any $\mu \in (0, \mu_T]$ *problem* (4.24) *has a solution* $u_\mu \in AC^1[0, T]$ *satisfying*

$$0 < u_\mu(t) < A \quad \textit{for } t \in (0, T). \tag{4.26}$$

Take notice of the fact that for any solution u of problem (4.24) there is a point $t_u \in (0, T)$ with $u'(t_u) = 0$. Since f has a singularity at $y = 0$ and we do not know the position of $t_u \in (0, T)$, t_u is a singular point of type II.

To prove Theorem 4.14 a two-parameter family of regular problems is constructed and their solvability is established by the topological transversality method. Then, a priori bounds for approximate solutions of regular problems are derived. Using these bounds and the Arzelà–Ascoli theorem, a solution of (4.24) is obtained by a limiting process.

EXAMPLE. Let $A > 0, a, b, c, d, \gamma \in [0, \infty)$, $a + b + d > 0$, $\alpha, \beta \in (0, 1)$. Then for a sufficiently small $\mu > 0$ the problem

$$\begin{aligned} &u'' + \mu\left(1 + \frac{a}{u^\alpha (A-u)^\beta} + bu^\gamma\right)\left(1 + cu'^2\right)\left(1 + \frac{d}{u'^2}\right) = 0, \\ &u(0) = u(T) = 0 \end{aligned}$$

has a solution u_μ satisfying (4.26). The upper bound μ_T is explicitly expressed in [135].

The next existence result is in the spirit of Staněk [139], where a more general state-dependent functional differential equation was studied. Here we consider problem (4.1) with the ϕ-Laplacian and a function f satisfying

$$\begin{cases} f \in Car\big([0, T] \times \mathcal{D}\big),\ \mathcal{D} = (0, \infty) \times \big(\mathbb{R} \setminus \{0\}\big), \\ \text{and } f \text{ can have space singularities at } x = 0,\ y = 0. \end{cases} \tag{4.27}$$

THEOREM 4.15. *Let* (4.27) *hold and let* ϕ *be odd. Suppose that there exists* $\delta \in (0, \infty)$ *such that* f *satisfies*

$$\delta \leqslant f(t, x, y) \leqslant \big(h_1(x) + h_2(x)\big)\big(\omega_1\big(\phi\big(|y|\big)\big) + \omega_2\big(\phi\big(|y|\big)\big)\big)$$

for a.e. $t \in [0, T]$ *and all* $(x, y) \in \mathcal{D}$, *where* $h_1, \omega_1 \in C[0, \infty)$ *are positive and nondecreasing*, $h_2, \omega_2 \in C(0, \infty) \cap L_1[0, 1]$ *are positive and nonincreasing and*

$$\int_0^\infty \frac{\mathrm{d}s}{\omega_1(s)} = \infty.$$

Let

$$\frac{T}{2} < \liminf_{u\to\infty} \frac{u}{K^{-1}(T(h_1(u)+h_2(u)))},$$

where K^{-1} denotes the inverse function to $K:[0,\infty)\to[0,\infty)$,

$$K(u) = \int_0^{\phi(u)} \frac{\mathrm{d}s}{\omega_1(s)+\omega_2(s)}.$$

Then problem (4.1) *has a positive solution $u \in AC^1[0,T]$.*

In the proof of this result the solvability of a sequence of regular problems is obtained by the Leray–Schauder degree theory. Limit processes are guaranteed by Vitali's convergence theorem.

EXAMPLE. Let $c \in L_\infty[0,T]$, $p \in (1,\infty)$, $\beta \in (0,1)$, $\gamma,\eta \in (0,p)$, $\delta \in (0,\infty)$ and $\alpha \in (0, p-\gamma)$. Further, let $c(t) \geqslant \delta$ a.e. on $[0,T]$. Then the problem

$$\begin{aligned}&\big(|u'|^{p-2}u'\big)' + c(t)\left(1+u^\alpha+\frac{1}{u^\beta}\right)\left(1+|u'|^\gamma+\frac{1}{|u'|^\eta}\right)=0,\\ &u(0)=u(T)=0\end{aligned}$$

has a positive solution.

4.3. *Sign-changing nonlinearities*

Results about the solvability of singular Dirichlet problems with sign-changing nonlinearities mostly concern w-solutions. Making use of the arguments of Section 1 we can show a new existence principle giving positive solutions to singular Dirichlet problems of the form

$$u'' + f(t,u,u') = 0, \quad u(0)=u(T)=0, \tag{4.28}$$

where

$$\begin{cases} f \in Car\big((0,T)\times\mathcal{D}\big) \text{ can change its sign, } \mathcal{D}=(0,\infty)\times\mathbb{R}, \\ \text{and } f \text{ can have mixed singularities at } t=0,\ t=T,\ x=0. \end{cases} \tag{4.29}$$

For $k\in\mathbb{N}$, $k\geqslant \frac{3}{T}$, $t\in[0,T]$, $x\in\mathbb{R}$, put $\Delta_k = [0,\frac{1}{k})\cup(T-\frac{1}{k},T]$,

$$\gamma_k(t)=\begin{cases}\frac{1}{k} & \text{if } t<\frac{1}{k},\\ t & \text{if } t\in[0,T]\setminus\Delta_k,\\ T-\frac{1}{k} & \text{if } t>T-\frac{1}{k},\end{cases} \qquad \delta_k(x)=\begin{cases}|x| & \text{if } |x|\geqslant\frac{1}{k},\\ \frac{1}{k} & \text{if } |x|<\frac{1}{k}.\end{cases}$$

Then we construct the sequence of regular functions

$$f_k(t,x,y) = f\big(\gamma_k(t), \delta_k(x), y\big) \quad \text{for a.e. } t \in [0,T], \text{ each } x, y \in \mathbb{R} \tag{4.30}$$

and the sequence of regular problems

$$u'' + f_k(t,u,u') = 0, \quad u(0) = u(T) = \frac{1}{k}, \tag{4.31}$$

where $f_k \in Car([0,T] \times \mathbb{R}^2)$, $k \in \mathbb{N}$, $k \geqslant \frac{3}{T}$.

THEOREM 4.16 (Existence principle for solutions of (4.28)). *Let* (4.29) *hold. Assume that*

$$\begin{cases} \textit{there exists a bounded set } \Omega \subset C^1[0,T] \textit{ such that} \\ \textit{problem } (4.31) \textit{ has a solution } u_k \in \Omega \textit{ for each } k \in \mathbb{N},\ k \geqslant \frac{3}{T}, \end{cases} \tag{4.32}$$

$$\begin{cases} \textit{there exists a function } \varepsilon \in C[0,T],\ \varepsilon(0) = \varepsilon(T) = 0, \\ \textit{such that } u_k(t) \geqslant \varepsilon(t) > 0 \textit{ for } t \in (0,T) \textit{ and each } k \in \mathbb{N},\ k \geqslant \frac{3}{T} \end{cases} \tag{4.33}$$

and

$$\textit{the sequence } \big\{f_k\big(t, u_k(t), u_k'(t)\big)\big\} \textit{ is uniformly integrable on } [0,T]. \tag{4.34}$$

Then

$$\begin{cases} \textit{there exist a function } u \in \overline{\Omega} \textit{ and a subsequence } \{u_{k_n}\} \subset \{u_k\} \\ \textit{such that } \lim_{n\to\infty} \|u_{k_n} - u\|_{C^1} = 0, \end{cases} \tag{4.35}$$

and

$$u \in AC^1[0,T] \textit{ is a positive solution of problem } (4.28). \tag{4.36}$$

PROOF. Since f can have singularities both at t and at x, we cannot obtain Theorem 4.16 as a direct consequence of some of the theorems in Section 1. Nevertheless, we can use the ideas of their proofs and argue as follows.

Step 1. *Convergence of the sequence of approximating solutions.*

By (4.32) we get that $\{u_k\}$ and $\{u_k'\}$ are bounded in $C[0,T]$. The boundedness of $\{u_k'\}$ implies the equicontinuity of $\{u_k\}$ on $[0,T]$. Condition (4.34) yields the equicontinuity of $\{u_k'\}$ on $[0,T]$ and hence the Arzelà–Ascoli theorem gives the assertion (4.35).

Step 2. *Convergence of the sequence of regular right-hand sides.*

The conditions $u_{k_n}(0) = u_{k_n}(T) = \frac{1}{k_n}$ imply $u(0) = u(T) = 0$. By (4.33) we get $u(t) > 0$ on $(0,T)$. Choose $\xi \in (0,T)$ such that $f(\xi, \cdot, \cdot) : \mathcal{D} \to \mathbb{R}$ is continuous. Then, by virtue of

(4.30) and (4.33), we have

$$u_{k_n}(\xi) \geqslant \varepsilon(\xi) > \frac{1}{k_n}, \quad \xi \in [0,T] \setminus \Delta_{k_n},$$
$$f_{k_n}\big(\xi, u_{k_n}(\xi), u'_{k_n}(\xi)\big) = f\big(\xi, u_{k_n}(\xi), u'_{k_n}(\xi)\big)$$

for a sufficiently large k_n. Therefore

$$\lim_{n\to\infty} f_{k_n}\big(t, u_{k_n}(t), u'_{k_n}(t)\big) = f\big(t, u(t), u'(t)\big) \quad \text{for a.e. } t \in [0,T]. \tag{4.37}$$

Step 3. *Properties of the limit u.*

By (4.34), (4.37) and Vitali's convergence theorem, we get that $f(t,u(t),u'(t))$ belongs to $L_1[0,T]$ and we can pass to the limit in the sequence

$$u'_{k_n}(t) = u'_{k_n}(0) - \int_0^t f_{k_n}\big(s, u_{k_n}(s), u'_{k_n}(s)\big)\,\mathrm{d}s, \quad t \in [0,T],$$

thus obtaining

$$u'(t) = u'(0) - \int_0^t f\big(s, u(s), u'(s)\big)\,\mathrm{d}s, \quad t \in [0,T].$$

Hence (4.36) is true. □

REMARK 4.17. Having in mind the absolute continuity of the Lebesgue integral we see that if there exists $\varphi \in L_1[0,T]$ such that

$$\big|f_k\big(t, u_k(t), u'_k(t)\big)\big| \leqslant \varphi(t) \quad \text{for a.e. } t \in [0,T] \text{ and each } k \in \mathbb{N},\ k \geqslant \tfrac{3}{T}, \tag{4.38}$$

then condition (4.34) is valid.

In Section 4.1, the classical lower and upper functions method has been extended to singular problems (see Theorems 4.6, 4.8, 4.11 and 4.12). Motivated by Agarwal, O'Regan, Lakshmikantham and Leela [13], we will show another approach which consists in the employment of a sequence of lower and upper functions of approximating regular problems.

THEOREM 4.18. *Let* (4.29) *and* (4.30) *hold. Assume that there exists $k_0 \in \mathbb{N}$ such that for each $k \in \mathbb{N}$, $k \geqslant k_0$, the following conditions are satisfied*:

$$\begin{cases} \alpha_k \textit{ and } \beta \textit{ are a lower and an upper function of } (4.31) \textit{ and} \\ \alpha'_k, \beta' \in L_\infty[0,T], \quad \frac{1}{k} \leqslant \alpha_k(t) \leqslant \beta(t) \quad \textit{for } t \in [0,T], \end{cases} \tag{4.39}$$

$$\begin{cases} \big|f_k(t,x,y)\big| \leqslant \psi(t) g(x) \omega(|y|) \quad \textit{for a.e. } t \in [0,T] \\ \textit{and for all } x \in \big(0, \|\beta\|_\infty\big),\ y \in \mathbb{R}, \end{cases} \tag{4.40}$$

with

$$\begin{cases} \text{positive functions } \psi \in L_1[\frac{1}{k}, T - \frac{1}{k}],\ \omega \in C[0,\infty) \text{ and} \\ \text{a positive nonincreasing function } g \in C(0,\infty). \end{cases} \tag{4.41}$$

Further, assume that there is a function $\alpha \in C[0,T]$ *with* $\alpha(0) = \alpha(T) = 0$, $\alpha > 0$ *on* $(0,T)$, $\alpha_k \geqslant \alpha$ *on* $[0,T]$, *such that*

$$\int_0^T \psi(t) g\bigl(\alpha(t)\bigr)\,\mathrm{d}t < \int_0^\infty \frac{\mathrm{d}s}{\omega(s)}. \tag{4.42}$$

Then problem (4.28) *has a positive solution* $u \in AC^1[0,T]$ *satisfying*

$$\alpha(t) \leqslant u(t) \leqslant \beta(t) \quad \textit{for } t \in [0,T].$$

SKETCH OF THE PROOF. Theorem 4.18 can be proved by means of Theorem 4.16 in the following way.

Step 1. *Construction of the sequence of regular problems.*

Condition (4.42) implies that there exists $\rho > 0$ such that

$$\int_0^T \psi(t) g\bigl(\alpha(t)\bigr)\,\mathrm{d}t < \int_0^\rho \frac{\mathrm{d}s}{\omega(s)}. \tag{4.43}$$

For $k \in \mathbb{N}$, $k \geqslant k_0$, put $\rho_k = \max\{\rho, \|\alpha_k'\|_\infty, \|\beta'\|_\infty\}$ and consider a sequence of regular problems

$$u'' + \widetilde{f}_k(t,u,u') = 0, \quad u(0) = u(T) = \frac{1}{k}, \tag{4.44}$$

where for a.e. $t \in [0,T]$ and all $(x,y) \in \mathbb{R}^2$ we set

$$\widetilde{f}_k(t,x,y) = \chi_k(y) f_k(t,x,y)$$

and

$$\chi_k(y) = \begin{cases} 1 & \text{if } |y| \leqslant \rho_k, \\ 2 - \frac{|y|}{\rho_k} & \text{if } \rho_k < |y| < 2\rho_k, \\ 0 & \text{if } |y| \geqslant 2\rho_k. \end{cases}$$

Then α_k and β are respectively a lower and an upper function of (4.44), $\widetilde{f}_k$ satisfies (4.40) and, moreover, there exists $\widetilde{h}_k \in L_1[0,T]$ such that

$$\bigl|\widetilde{f}_k(t,x,y)\bigr| \leqslant \widetilde{h}_k(t) \quad \text{for a.e. } t \in [0,T],\ \text{all } x \in \bigl[\alpha_k(t), \beta(t)\bigr],\ y \in \mathbb{R}.$$

The classical existence result based on the lower and upper functions method for regular problems (see, e.g., [146]) guarantees that for each $k \geqslant k_0$ problem (4.44) has a solution u_k with

$$\alpha \leqslant \alpha_k \leqslant u_k \leqslant \beta \quad \text{on } [0, T]. \tag{4.45}$$

Step 2. *A priori estimates of approximate solutions.*

Using (4.40), (4.41) and (4.43) we deduce that $\|u_k'\|_\infty \leqslant \rho$, which implies that u_k is also a solution of (4.31) for $k \geqslant k_0$. Hence, if we put $\varepsilon(t) = \alpha(t)$ for $t \in [0, T]$ and

$$\Omega = \bigl\{x \in C^1[0, T]\colon\ \alpha \leqslant x \leqslant \beta \text{ on } [0, T],\ \|x'\|_\infty \leqslant \rho\bigr\},$$

we get that (4.32), (4.33) are fulfilled.

Step 3. *Uniform integrability of regular right-hand sides.*

By (4.40), (4.41) and (4.45) we get

$$\bigl|f_k\bigl(t, u_k(t), u_k'(t)\bigr)\bigr| \leqslant \psi(t)g\bigl(u_k(t)\bigr)\omega\bigl(\bigl|u_k'(t)\bigr|\bigr) \leqslant M\psi(t)g\bigl(\alpha(t)\bigr) = \varphi(t)$$

for a.e. $t \in [0, T]$, where $M = \max\{\omega(|s|)\colon\ s \in [-\rho, \rho]\}$. By virtue of (4.43), $\varphi \in L_1[0, T]$ and we conclude by Remark 4.17 that condition (4.34) is valid. Therefore the assertion follows from Theorem 4.16 and condition (4.45). ☐

REMARK 4.19. If f does not depend on y, then (4.42) takes the form

$$\int_0^T \psi(t)g\bigl(\alpha(t)\bigr)\,\mathrm{d}t < \infty.$$

In the rest of this section we present a selection of existence results about w-solutions which can be obtained by theorems from Section 4.1. Consider a singular Dirichlet problem

$$u'' + f(t, u) = 0, \quad u(0) = u(T) = 0, \tag{4.46}$$

where

$$\begin{cases} f \in Car\bigl((0, T) \times (0, \infty)\bigr) \text{ can change its sign and} \\ \text{can have singularities at } t = 0,\ t = T \text{ and at } x = 0. \end{cases} \tag{4.47}$$

The first result is due to Lomtatidze [99].

THEOREM 4.20. *Let* (4.47) *hold. Assume that* f *is nonincreasing as a function of its second argument and that there is* $\varepsilon > 0$ *for which*

$$f(t, \varepsilon) \geqslant 0 \quad \textit{for a.e. } t \in [0, T], \operatorname{meas}\bigl\{t \in (0, T)\colon\ f(t, \varepsilon) > 0\bigr\} > 0.$$

Then the condition

$$\int_0^T t(T-t)\bigl|f(t,\delta)\bigr|\,\mathrm{d}t < \infty \quad \textit{for any } \delta \in (0,\varepsilon]$$

is necessary and sufficient for problem (4.46) *to have a unique positive w-solution* $u \in C[0,T] \cap AC^1_{loc}(0,T)$.

The proof of Theorem 4.20 is based on the lower and upper functions method via Theorem 4.11. More general results were obtained by Lomtatidze and Torres in [100], where a differential equation having moreover the term $g(t,u)u'$ was investigated.

A very similar result for a simpler case of problem (4.46) with f satisfying (4.49) was proved by Habets and Zanolin in [80]. The analogue of their results was proved by Jiang [86] for a singular Dirichlet problem with the p-Laplacian

$$\bigl(\phi_p(u')\bigr)' + f(t,u) = 0, \quad u(0) = u(T) = 0, \tag{4.48}$$

where $\phi(y) = |y|^{p-2}y,\ p > 1$ and

$$\begin{cases} f \in C\bigl((0,T) \times (0,\infty)\bigr) \text{ can change its sign and} \\ \text{can have singularities at } t = 0,\ t = T \text{ and at } x = 0. \end{cases} \tag{4.49}$$

THEOREM 4.21 [86, Theorem 3]. *Let* (4.49) *hold. Assume that*

(i) *there exists a constant* $L > 0$ *such that for any compact set* $K \subset (0,T)$ *there is* $\varepsilon = \varepsilon_K > 0$ *such that*

$$f(t,x) > L \quad \textit{for all } t \in K,\ x \in (0,\varepsilon],$$

(ii) *for any* $\delta > 0$ *there are* $h_\delta \in C(0,T)$ *and* $\mu, \nu \in [0, p-1)$ *such that*

$$\bigl|f(t,x)\bigr| \leqslant h_\delta(t) \quad \textit{for all } t \in (0,T),\ x \geqslant \delta$$

and

$$\int_0^T t^\mu (T-t)^\nu h_\delta(t)\,\mathrm{d}t < \infty.$$

Then problem (4.48) *has a positive w-solution* $u \in C[0,T]$ *with* $\phi_p(u') \in C^1(0,T)$. *If, moreover, for each* $t \in (0,T)$ *the function* $f(t,x)$ *is nonincreasing in* x, *then* u *is a unique w-solution.*

Another existence result for differential equation where the nonlinearity f can depend on u' is due to Jiang in [87]. He studied the singular Dirichlet problem of the form

$$u'' + f(t,u,u') = 0, \quad u(0) = u(1) = 0, \tag{4.50}$$

where

$$\begin{cases} f \in C((0,1)\times(0,\infty)\times\mathbb{R}) \text{ can change its sign} \\ \text{and can have singularities at } t=0,\ t=1 \text{ and } x=0. \end{cases} \tag{4.51}$$

Motivated by the example

$$f(t,x,y)=\frac{\delta}{t^m(1-t)^n}\left(\frac{1}{x^\alpha}+x^\beta+\sin(8\pi t)\right)\bigl(1+t(1-t)|y|^{1/\gamma}\bigr) \tag{4.52}$$

with real numbers $\alpha>0$, $\beta\geqslant 0$, $\gamma>1$, $\delta>0$, $0\leqslant m,n<2$, he proved existence of a positive w-solution of (4.50) for f satisfying (4.51) and having superlinear growth in x for large x and sublinear growth in y for large $|y|$. Particularly, if f in (4.50) has the form (4.52), then an upper bound for δ is found guaranteeing that (4.50) has a positive w-solution. The proof is based on the papers [80] and [4].

Let us turn back to problem (4.17). Using the lower and upper functions method established in Theorem 4.12 we can get sufficient conditions for the existence of positive w-solutions. Specifically, we report the result motivated by Agarwal, Lü and O'Regan [2].

THEOREM 4.22. *Let* (4.18)–(4.21) *hold. Assume that there exist* $n_0\in\mathbb{N}$, $n_0\geqslant 3$ *and* $c_0\in(0,\infty)$ *such that*

$$\psi(t)g(t,x)\geqslant c_0 \quad \textit{for } t\in\left[\frac{1}{2^{n+1}},1-\frac{1}{2^{n+1}}\right],\ x\in(0,\rho_n],\ n\geqslant n_0$$

and

$$\bigl|g(t,x)\bigr|\leqslant \eta(x)+h(x) \quad \textit{for } (t,x)\in[0,1]\times(0,\infty),$$

where $\eta\in AC_{loc}(0,\infty)$ *is positive*, $h\in C[0,\infty)$ *is nonnegative and* $\frac{h}{\eta}$ *is nondecreasing on* $(0,\infty)$. *Further assume that*

$$\eta'<0 \quad \textit{a.e. on } (0,R) \quad \textit{and} \quad \frac{\eta'}{\eta^2}\in L_1[0,R] \quad \textit{for any } R>0$$

and that there exists $r\in(0,\infty)$ *such that*

$$b_0<\left(\phi_p^{-1}\left(1+\frac{h(r)}{\eta(r)}\right)\right)^{-1}\int_0^r\frac{\mathrm{d}u}{\phi_p^{-1}(\eta(u))}.$$

Then problem (4.17) *has a positive w-solution* $u\in C[0,1]$ *with* $\phi_p(u')\in C^1(0,1)$.

4.4. *Sign-changing solutions and w-solutions*

If we consider a singular differential equation with a space singularity at $x = 0$, a question about the existence of sign-changing solutions of such an equation can arise. A single result in this direction was proved by Rachůnková and Staněk in [118], where an equation of the form $(r(u)u')' = \mu q(t) f(t, u)$ has been studied.

Here we will present this result for a simplified equation

$$u'' + \mu f(t, u) = 0 \tag{4.53}$$

with a positive real parameter μ and with boundary conditions

$$u(0) = u(T) = 0, \quad \max\{u(t)\colon\ t \in [0, T]\} \min\{u(t)\colon\ t \in [0, T]\} < 0. \tag{4.54}$$

We assume that

$$\begin{cases} f : [0, T] \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R} \text{ is continuous} \\ \text{and can have a space singularity at } x = 0. \end{cases} \tag{4.55}$$

By a *solution of problem* (4.53), (4.54) we mean a function $u \in C^1[0, T]$ having precisely one zero $t_u \in (0, T)$. Moreover, $u \in C^2((0, T) \setminus \{t_u\})$ fulfills (4.54) and there exists $\mu_u > 0$ such that u satisfies (4.53) for $\mu = \mu_u$ and $t \in (0, T) \setminus \{t_u\}$.

THEOREM 4.23. *Let* (4.55) *hold. Assume that for each* $t \in [0, T]$ *the function* $f(t, x)$ *is nondecreasing with respect to* x *on* $(-\infty, 0)$ *and nonincreasing on* $(0, \infty)$ *and*

$$\varepsilon \leqslant f(t, x) \operatorname{sign} x \leqslant g(x) \quad \textit{for } (t, x) \in [0, T] \times \big(\mathbb{R} \setminus \{0\}\big),$$

where $\varepsilon \in (0, \infty)$ *and* $g \in C(\mathbb{R} \setminus \{0\}) \cap L_1[-1, 1]$. *Then for each* $A \in (0, \infty)$ *and* $B \in (-\infty, 0)$ *there exist solutions* u *and* v *of problem* (4.53), (4.54) *satisfying*

$$\max\{u(t)\colon\ t \in [0, T]\} = A \quad \textit{and} \quad \min\{v(t)\colon\ t \in [0, T]\} = B. \tag{4.56}$$

By virtue of Theorem 4.23, any solution u of problem (4.53), (4.54) vanishes at some point $t_u \in (0, T)$. Since f has a singularity at $x = 0$ and we do not know the position of t_u, we see that t_u is a singular point of type II.

The proof of Theorem 4.23 is based on a combination of four main theorems in [118], where a new method of proofs was developed. It is based on “gluing” the positive and negative parts of solutions and smoothing them.

In accordance with the paper [119] by Rachůnková and Staněk we define *a w-solution of problem* (4.53), (4.54) as a function $u \in C[0, T]$ having precisely one zero $t_u \in (0, T)$. Further, $u \in C^2((0, T) \setminus \{t_u\})$ fulfills (4.54), there exist finite limits

$$\lim_{t \to t_u-} u'(t), \quad \lim_{t \to t_u+} u'(t)$$

and there exists $\mu_u > 0$ such that u satisfies (4.53) for $\mu = \mu_u$ and $t \in (0,T) \setminus \{t_u\}$.

In [119], the following existence result for w-solutions is proved.

THEOREM 4.24. *Let all assumptions of Theorem* 4.23 *be satisfied. Then for each* $t_0 \in (0,T)$ *and each* $A \in (0,\infty)$, $B \in (-\infty,0)$ *problem* (4.53), (4.54) *has just two different w-solutions vanishing at* t_0 *and having their maximum value on* $[0,T]$ *equal to* A, *and just two different w-solutions vanishing at* t_0 *and having their minimum value on* $[0,T]$ *equal to* B.

In the proof of Theorem 4.24, w-solutions are constructed by means of solutions of auxiliary Dirichlet problems on $[0,t_0]$ and $[t_0,T]$.

EXAMPLE. Let $\alpha, \beta \in (0,1)$, $a \in (0,\infty)$, $b \in (-\infty,0)$ and

$$f(x) = \begin{cases} \frac{a}{x^\alpha} & \text{for } x > 0, \\ \frac{b}{(-x)^\beta} & \text{for } x < 0. \end{cases}$$

Consider the differential equation

$$u'' + \mu f(u) = 0. \tag{4.57}$$

By Theorem 4.23, for each $A > 0$ and $B < 0$ there exist solutions u and v of problem (4.57), (4.54) satisfying (4.56). Moreover, by Theorem 4.24, for each $t_0 \in (0,T)$ and for each $A > 0$ there exist just two different w-solutions u_1 and u_2 of problem (4.57), (4.54) satisfying

$$\max\{u_1(t)\colon t \in [0,T]\} = \max\{u_2(t)\colon t \in [0,T]\} = A.$$

Further, for each $t_0 \in (0,T)$ and for each $B < 0$ there exist just two different w-solutions v_1 and v_2 of problem (4.57), (4.54) satisfying

$$\min\{v_1(t)\colon t \in [0,T]\} = \min\{v_2(t)\colon t \in [0,T]\} = B.$$

4.5. *Historical and bibliographical notes*

A systematic study of solvability of Dirichlet problems having both time and space singularities was initiated in 1979 by Taliaferro [141], who found necessary and sufficient conditions for the existence of solutions (w-solutions) of problem (1.3), (1.4). A contribution to the more general problem (4.22) was published by Bobisud, O'Regan and Royalty [37] in 1988. In 1989, in contrast to the shooting method used in [141] and the topological transversality method applied in [37], Gatica, Oliker and Waltman [72] proved a fixed point theorem for decreasing maps on cones and applying it they obtained solvability of (4.14). However, in these works the nonlinearity f had to be bounded in its space variables x and y for large x and large $|y|$.

An extension of the above results permitting linear growth of f in its third variable y for large $|y|$ was treated by Baxley [24] in 1991 and by Tineo [142] in 1992. The condition of boundedness of f in its second variable x for large x was overcome by Agarwal and O'Regan in [3] (1996), where the existence of a positive w-solution was proved even for f having superlinear growth for large x. In 1999, the first multiplicity result for Dirichlet problems with time and space singularities was reached. Particularly, Agarwal and O'Regan [6] proved the existence of two different positive w-solutions. All these results rely on the fact that nonlinearities in the equations considered are positive.

In 1987, this assumption was removed by Lomtatidze [99] for problem (4.14). We can also refer to papers by Janus and Myjak [83] for a nonhomogeneous equation (1.3) and by Habets and Zanolin [80] for the continuous case of (4.14) which appeared in 1994. From papers providing more general existence results for problems with sign-changing nonlinearities we mention the recent papers by Jiang [87] (2002), by Agarwal, Staněk [17] (2003) or by Lomtatidze, Torres [100] (2003). These papers deal with problems of the type (4.2).

Existence results for problems of the type (4.1) with the ϕ-Laplacian and sign-changing nonlinearities were presented by Wang and Gao in [149] (1996), where Taliaferro's results were extended. Existence results in the spirit of Habets and Zanolin which are applicable to problems with the p-Laplacian of the form (4.48) were given by Jiang in [86] (2001). In 2003, Agarwal, Lü and O'Regan [2] published the existence result for the problem with the p-Laplacian of the form (4.17).

Further results and references for positive and for sign-changing nonlinearities can be found in the monographs by Kiguradze [92] (1975), by Kiguradze and Shekhter [93] (1987), by O'Regan [110] (1994), by Agarwal and O'Regan [10] (2003) and in [11] (2004). Note that there exists a large group of papers investigating Dirichlet boundary value problems having only time singularities. These results are not discussed here but some of them can be found in the above cited monographs.

In the study of Dirichlet problems with space singularities and singular points both of type I and of type II the first existence result was reached by Staněk [135] in 2001, and the existence of sign-changing solutions was proved by Rachůnková and Staněk [118] in 2003. Numerical algorithms and computation of solutions and w-solutions of singular Dirichlet problems were given by Baxley [25] (1995) and by Baxley and Thompson [28] (2000).

5. Singular periodic BVPs with ϕ-Laplacian

The aim of this section is to present existence results for singular periodic problems of the form

$$\big(\phi(u')\big)' = f(t, u, u'), \tag{5.1}$$

$$u(0) = u(T), \quad u'(0) = u'(T), \tag{5.2}$$

where $0 < T < \infty$, $\phi : \mathbb{R} \to \mathbb{R}$ is an increasing and odd homeomorphism such that $\phi(\mathbb{R}) = \mathbb{R}$ and

$$\begin{cases} f \in Car\big([0,T] \times \big((0,\infty) \times \mathbb{R}\big)\big) \quad \text{and} \\ f \text{ can have a space singularity at } x = 0. \end{cases} \tag{5.3}$$

In accordance with Section 1.3, this means that

$$\limsup_{x \to 0+} \big| f(t,x,y) \big| = \infty \quad \text{for a.e. } t \in [0,T] \text{ and some } y \in \mathbb{R}$$

may happen.

REMARK 5.1. Physicists say that f has an *attractive* singularity at $x = 0$ if

$$\liminf_{x \to 0+} f(t,x,y) = -\infty \quad \text{for a.e. } t \in [0,T] \text{ and some } y \in \mathbb{R}$$

since near the origin the force is directed inward. Alternatively, f is said to have a *repulsive* singularity at $x = 0$ if

$$\limsup_{x \to 0+} f(t,x,y) = \infty \quad \text{for a.e. } t \in [0,T] \text{ and some } y \in \mathbb{R}$$

holds.

In the setting of Section 1.3, problem (5.1), (5.2) is investigated on the set $[0,T] \times \mathcal{A}$, where $\mathcal{A} = [0,\infty) \times \mathbb{R}$. In contrast to the Dirichlet problem (4.1), where each solution vanishes at $t = 0$ and $t = T$ and hence enters the space singularity $x = 0$ of f, all known existence results for the periodic problem (5.1), (5.2) under the assumption (5.3) concern positive solutions which do not touch the space singularity $x = 0$ of the function f.

DEFINITION 5.2. A function $u : [0,T] \to \mathbb{R}$ is a *positive solution* to problem (5.1), (5.2) if $\phi(u') \in AC[0,T]$, $u > 0$ on $[0,T]$, $(\phi(u'(t)))' = f(t,u(t),u'(t))$ for a.e. $t \in [0,T]$ and (5.2) is satisfied.

The restriction to positive solutions causes that the general existence principle in Theorem 1.8 about a limit of a sequence of approximate solutions need not be employed here. On the other hand, the singular problem (5.1), (5.2) will be also investigated through regular approximating periodic problems having differential equations of the form

$$\big(\phi(u')\big)' = h(t,u,u'), \tag{5.4}$$

where $h \in Car([0,T] \times \mathbb{R}^2)$. As usual, by a *solution of the regular problem* (5.4), (5.2) we understand a function u such that $\phi(u') \in AC[0,T]$, (5.2) is true and $(\phi(u'(t)))' = h(t,u(t),u'(t))$ for a.e. $t \in [0,T]$.

Notice that the requirement $\phi(u') \in AC[0,T]$ implies that $u \in C^1[0,T]$.

We will also discuss various special cases of (5.1) including the classical one with $\phi(y) \equiv y$ or those with f not depending on u' or with f depending on u' linearly.

Let us notice that the assumption that ϕ is an odd function is only technical and it is sufficient to assume (3.3) as in Section 3 in most cases. We employ it just to simplify some formulas occurring in this section.

5.1. *Method of lower and upper functions for regular problems*

First, we will consider problem (5.4), (5.2), where $h \in Car([0,T] \times \mathbb{R}^2)$. We bring some results which will be exploited in the investigation of the singular problem (5.1), (5.2). The lower and upper functions method combined with the topological degree argument is an important tool for proofs of solvability of regular periodic problems. Several rather general definitions of lower and upper functions are available (see, e.g., [47,48,62,93,124, 147]). However, for our purposes the following one seems to be optimal.

DEFINITION 5.3. We say that a function $\sigma \in C[0,T]$ is a *lower function* of problem (5.4), (5.2) if there is a finite set $\Sigma \subset (0,T)$ such that $\phi(\sigma') \in AC_{loc}([0,T] \setminus \Sigma)$, $\sigma'(\tau+)$, $\sigma'(\tau-) \in \mathbb{R}$ for each $\tau \in \Sigma$ and

$$\big(\phi\big(\sigma'(t)\big)\big)' \geqslant h\big(t, \sigma(t), \sigma'(t)\big) \quad \text{for a.e. } t \in [0,T], \tag{5.5}$$

$$\sigma(0) = \sigma(T), \quad \sigma'(0) \geqslant \sigma'(T), \tag{5.6}$$

$$\sigma'(\tau+) > \sigma'(\tau-) \quad \text{for all } \tau \in \Sigma. \tag{5.7}$$

If the inequalities in (5.5)–(5.7) are reversed, σ is called an *upper function* of problem (5.4), (5.2).

The role of lower and upper functions is demonstrated by the following "maximum principle":

LEMMA 5.4. *Let σ_1 and σ_2 be a lower and an upper function of* (5.4), (5.2) *and* $\sigma_1 \leqslant \sigma_2$ *on* $[0,T]$. *Then for each $d \in [\sigma_1(0), \sigma_2(0)]$ and each $\tilde{f} \in Car([0,T] \times \mathbb{R}^2)$ such that*

$$\begin{cases} \tilde{f}(t,x,y) < h\big(t, \sigma_1(t), \sigma_1'(t)\big) \textit{ for a.e. } t \in [0,T], \textit{ all } x \in \big(-\infty, \sigma_1(t)\big) \\ \quad \textit{and all } y \in \mathbb{R} \textit{ such that } \big|y - \sigma_1'(t)\big| \leqslant \dfrac{\sigma_1(t) - x}{\sigma_1(t) - x + 1}, \\ \tilde{f}(t,x,y) > h\big(t, \sigma_2(t), \sigma_2'(t)\big) \textit{ for a.e. } t \in [0,T], \textit{ all } x \in \big(\sigma_2(t), \infty\big) \\ \quad \textit{and all } y \in \mathbb{R} \textit{ such that } \big|y - \sigma_2'(t)\big| \leqslant \dfrac{x - \sigma_2(t)}{x - \sigma_2(t) + 1}, \end{cases} \tag{5.8}$$

any solution u of the problem

$$\big(\phi(u')\big)' = \tilde{f}(t,u,u'), \quad u(0) = u(T) = d$$

satisfies $\sigma_1 \leqslant u \leqslant \sigma_2$ *on* $[0, T]$.

PROOF. Denote $v = u - \sigma_1$ and assume that $v(\alpha) = \min\{v(t)\colon t \in [0, T]\} < 0$. Since $d \in [\sigma_1(0), \sigma_2(0)]$ and thanks to (5.6) and (5.7), we may assume that $\alpha \in (0, T) \setminus \Sigma$, $v'(\alpha) = 0$, and there is $\beta \in (\alpha, T]$ such that $(\alpha, \beta] \cap \Sigma = \emptyset$ and

$$v(t) < 0 \quad \text{and} \quad \left|v'(t)\right| < \frac{-v(t)}{1 - v(t)} \quad \text{for all } t \in [\alpha, \beta].$$

Using (5.5) (where $\sigma = \sigma_1$) and (5.8), we obtain

$$\bigl(\phi\bigl(u'(t)\bigr) - \phi\bigl(\sigma_1'(t)\bigr)\bigr)' < h\bigl(t, \sigma_1(t), \sigma_1'(t)\bigr) - \bigl(\phi\bigl(\sigma_1'(t)\bigr)\bigr)' \leqslant 0$$
$$\text{for a.e. } t \in [\alpha, \beta].$$

Hence

$$0 > \int_\alpha^t \bigl(\phi\bigl(u'(s)\bigr) - \phi\bigl(\sigma_1'(s)\bigr)\bigr)' \,\mathrm{d}s = \phi\bigl(u'(t)\bigr) - \phi\bigl(\sigma_1'(t)\bigr) \quad \text{for all } t \in (\alpha, \beta],$$

which leads to a contradiction with the definition of α, i.e. $u \geqslant \sigma_1$ on $[0, T]$. Similarly we can show that $u \leqslant \sigma_2$ on $[0, T]$. □

Problem (5.4), (5.2) is often transformed to a fixed point problem (see, e.g., [41,101,104, 150]). Here we present one possibility how to find an operator representation of (5.4), (5.2) in the space $C^1[0, T]$. Having in mind that the periodic conditions (5.2) can be equivalently rewritten as

$$u(0) = u(T) = u(0) + u'(0) - u'(T),$$

let us consider the quasilinear Dirichlet problem

$$\bigl(\phi(x')\bigr)' = b(t) \quad \text{a.e. on } [0, T], \quad x(0) = x(T) = d \tag{5.9}$$

with $b \in L_1[0, T]$ and $d \in \mathbb{R}$. A function $x \in C^1[0, T]$ is a solution of (5.9) if and only if there is $a \in \mathbb{R}$ such that

$$x(t) = d + \int_0^t \phi^{-1}\left(a + \int_0^s b(\tau)\,\mathrm{d}\tau\right)\mathrm{d}s \quad \text{for } t \in [0, T]$$

and

$$\int_0^T \phi^{-1}\left(a + \int_0^s b(\tau)\,\mathrm{d}\tau\right)\mathrm{d}s = 0. \tag{5.10}$$

Since ϕ is increasing on $\mathbb{R}$ and $\phi(\mathbb{R}) = \mathbb{R}$, Eq. (5.10) has exactly one solution $a = a(b) \in \mathbb{R}$ for each $b \in L_1[0, T]$. So, we can define an operator $\mathcal{K}: L_1[0, T] \to C^1[0, T]$ by

$$\big(\mathcal{K}(b)\big)(t) = \int_0^t \phi^{-1}\left(a(b) + \int_0^s b(\tau)\,\mathrm{d}\tau\right)\mathrm{d}s \quad \text{for } t \in [0, T]. \tag{5.11}$$

Let $\mathcal{N}: C^1[0, T] \to L_1[0, T]$ and $\mathcal{F}: C^1[0, T] \to C^1[0, T]$ have the form $(\mathcal{N}(u))(t) = h(t, u(t), u'(t))$ for a.e. $t \in [0, T]$ and

$$\big(\mathcal{F}(u)\big)(t) = u(0) + u'(0) - u'(T) + \big(\mathcal{K}\big(\mathcal{N}(u)\big)\big)(t) \quad \text{for } t \in [0, T]. \tag{5.12}$$

In view of the definition of $\mathcal{K}$, a function $x \in C^1[0, T]$ is a solution to (5.9) if and only if $x = d + \mathcal{K}(b)$. Therefore, $u \in C^1[0, T]$ is a solution to (5.4), (5.2) if and only if it is a fixed point of $\mathcal{F}$.

An alternative representation of the operator $\mathcal{F}$ can be obtained by inserting $\alpha(u) = u(0) - d$, $\beta(u) = d - u(T)$ and $d = u(0) + u'(0) - u'(T)$ into the operator $\mathcal{P}(1, u)$ defined in the proof of Theorem 3.2. In this way we get

$$\begin{aligned}\big(\mathcal{F}(u)\big)(t) &= u(0) + u'(0) - u'(T) \\ &\quad + \int_0^t \phi^{-1}\left(\phi\big(u'(T) + u(T) - u(0)\big) + \int_0^s \big(\mathcal{N}(u)\big)(\tau)\,\mathrm{d}\tau\right)\mathrm{d}s\end{aligned}$$

for $t \in [0, T]$ and $u \in C^1[0, T]$.

Taking into account [101, Proposition 2.2] or the proof of Theorem 3.2, we can summarize:

LEMMA 5.5. *Let $\mathcal{F}: C^1[0, T] \to C^1[0, T]$ be defined by* (5.12). *Then $\mathcal{F}$ is completely continuous and $u \in C^1[0, T]$ is a solution to* (5.4), (5.2) *if and only if $\mathcal{F}(u) = u$.*

The next lemma describes the relationship between lower and upper functions and the Leray–Schauder topological degree. We will consider the class of auxiliary problems

$$\big(\phi(v')\big)' = \eta(v')h(t, v, v'), \quad v(0) = v(T), \quad v'(0) = v'(T), \tag{5.13}$$

where $\eta: \mathbb{R} \to [0, 1]$ may be an arbitrary continuous function.

LEMMA 5.6. *Let σ_1 and σ_2 be a lower and an upper function of* (5.4), (5.2) *and $\sigma_1 < \sigma_2$ on* $[0, T]$. *Furthermore, let there exist $r^* > 0$ such that*

$$\begin{cases} \|v'\|_\infty < r^* & \textit{for each continuous } \eta: \mathbb{R} \to [0, 1] \textit{ and for} \\ \textit{each solution } v \textit{ of } (5.13) \textit{ such that } \sigma_1 \leqslant v \leqslant \sigma_2 \textit{ on } [0, T]. \end{cases} \tag{5.14}$$

Finally, assume that $\mathcal{F}: C^1[0, T] \to C^1[0, T]$ is defined by (5.12) *and, for $\rho > 0$, denote*

$$\Omega_\rho = \big\{u \in C^1[0, T]\colon \sigma_1 < u < \sigma_2 \textit{ on } [0, T] \textit{ and } \|u'\|_\infty < \rho\big\}. \tag{5.15}$$

Then

$$\deg(\mathcal{I}-\mathcal{F},\Omega_\rho)=1 \quad \textit{for each } \rho \geqslant r^* \textit{ such that } \mathcal{F}(u)\neq u \textit{ on } \partial\Omega_\rho.$$

PROOF. Put $\Omega=\Omega_{r^*}$, $R^*=r^*+\|\sigma_1'\|_\infty+\|\sigma_2'\|_\infty$,

$$\eta(y)=\begin{cases}1 & \text{if } |y|\leqslant R^*,\\ 2-\frac{|y|}{R^*} & \text{if } R^*<|y|\leqslant 2R^*,\\ 0 & \text{if } |y|>2R^*\end{cases}$$

and assume that $\mathcal{F}(x)\neq x$ for all $x\in\partial\Omega$. Then σ_1 and σ_2 are a lower and an upper function for the modified problem (5.13) and there is a $\psi\in L_1[0,T]$ satisfying

$$\bigl|\eta(y)h(t,x,y)\bigr|\leqslant\psi(t) \quad \text{for a.e. } t\in[0,T] \text{ and all } (x,y)\in[\sigma_1(t),\sigma_2(t)]\times\mathbb{R}.$$

We can construct (see the proof of Theorem 2.1 in [127]) the function $\widetilde{f}\in Car([0,T]\times\mathbb{R}^2)$ so that

$$\begin{aligned}&\widetilde{f}(t,x,y)=\eta(y)h(t,x,y)\\ &\quad\text{for a.e. } t\in[0,T] \text{ and all } (x,y)\in[\sigma_1(t),\sigma_2(t)]\times\mathbb{R},\\ &\bigl|\widetilde{f}(t,x,y)\bigr|\leqslant\widetilde{\psi}(t)\\ &\quad\text{for a.e. } t\in[0,T],\ \text{all } (x,y)\in\mathbb{R}^2 \text{ and some } \widetilde{\psi}\in L_1[0,T]\end{aligned}$$

and $\widetilde{f}$ satisfies the assumptions of Lemma 5.4 with $\eta(y)h(t,x,y)$ in place of $h(t,x,y)$. Define $\widetilde{\mathcal{F}}: C^1[0,T]\to C^1[0,T]$ by

$$\widetilde{\mathcal{F}}(u)=\alpha\bigl(u(0)+u'(0)-u'(T)\bigr)+\mathcal{K}\bigl(\widetilde{\mathcal{N}}(u)\bigr),$$

where

$$\bigl(\widetilde{\mathcal{N}}(u)\bigr)(t)=\widetilde{f}\bigl(t,u(t),u'(t)\bigr) \quad \text{for } u\in C^1[0,T] \text{ and a.e. } t\in[0,T],$$

$$\alpha(x)=\begin{cases}\sigma_1(0) & \text{if } x<\sigma_1(0),\\ x & \text{if } \sigma_1(0)\leqslant x\leqslant\sigma_2(0),\\ \sigma_2(0) & \text{if } x>\sigma_2(0)\end{cases}$$

and let $\mathcal{K}: L_1[0,T]\to C^1[0,T]$ be given in (5.11). By Lemma 5.5, the operator $\widetilde{\mathcal{F}}$ is completely continuous. Moreover, it follows from the definition of the operator $\mathcal{K}$ that the problem

$$\bigl(\phi(u')\bigr)'=\widetilde{f}(t,u,u'), \quad u(0)=u(T)=\alpha\bigl(u(0)+u'(0)-u'(T)\bigr)$$

is equivalent to the operator equation $\widetilde{\mathcal{F}}(u) = u$. We can find $r_0 \in (0, \infty)$ such that for any $\lambda \in [0, 1]$, each fixed point u of the operator $\lambda\widetilde{\mathcal{F}}$ belongs to $\mathcal{B}(r_0) = \{x \in C^1[0, T]\colon \|x\|_\infty + \|x'\|_\infty < r_0\}$. So, $\mathcal{I} - \lambda\widetilde{\mathcal{F}}$ is a homotopy on $\overline{\mathcal{B}}(r_0) \times [0, 1]$ and

$$\deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \mathcal{B}(r_0)\bigr) = \deg\bigl(\mathcal{I}, \mathcal{B}(r_0)\bigr) = 1.$$

Put $\Omega_1 = \{u \in \Omega\colon \sigma_1(0) < u(0) + u'(0) - u'(T) < \sigma_2(0)\}$. Clearly, $\widetilde{\mathcal{F}} = \mathcal{F}$ on $\overline{\Omega}_1$ and $u \in \Omega_1$ whenever $\mathcal{F}(u) = u$ and $u \in \Omega$. Using Lemma 5.4, we can prove that

$$\bigl(\widetilde{\mathcal{F}}(u) = u\bigr) \quad\Longrightarrow\quad u \in \Omega_1$$

which, by the excision property of the degree, yields

$$\deg(\mathcal{I} - \mathcal{F}, \Omega) = \deg(\mathcal{I} - \mathcal{F}, \Omega_1) = \deg(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_1) = \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \mathcal{B}(r_0)\bigr) = 1.$$

Finally, according to (5.14) all fixed points u of $\mathcal{F}$ such that $\sigma_1 < u < \sigma_2$ on $[0, T]$ belong to Ω. Thus

$$\deg(\mathcal{I} - \mathcal{F}, \Omega_\rho) = \deg(\mathcal{I} - \mathcal{F}, \Omega) = 1$$

for each $\rho \geqslant r^*$ such that $\mathcal{F}(x) \neq x$ on $\partial\Omega_\rho$. □

Lemma 5.6 offers a possibility to get existence results for problems having a pair of lower and upper functions σ_1 and σ_2 satisfying

$$\sigma_1 \leqslant \sigma_2 \quad \text{on } [0, T]. \tag{5.16}$$

In such a case we say that σ_1 and σ_2 are *well-ordered* and the existence of an a priori estimate r^* with the property (5.14) is usually ensured by conditions of Nagumo type. The most general known version of such conditions is provided by the next lemma which is a modified version of the result by Staněk [133, Lemma 1].

LEMMA 5.7. *Let* $\sigma_1, \sigma_2 \in C[0, T]$ *satisfy* (5.16) *and assume that*

$$\begin{cases} \psi \in L_1[0, T] \text{ is nonnegative}, \ \varepsilon_1, \varepsilon_2 \in \{-1, 1\}, \\ \omega \in C(\mathbb{R}) \text{ is positive and } \displaystyle\int_{-\infty}^{0} \frac{\mathrm{d}s}{\omega(s)} = \int_0^\infty \frac{\mathrm{d}s}{\omega(s)} = \infty. \end{cases} \tag{5.17}$$

Then there is an $r^* > 0$ *such that*

$$\|v'\|_\infty < r^* \tag{5.18}$$

holds for each $v \in C^1[0,T]$ *such that* $\phi(v') \in AC[0,T]$, $v(0) = v(T)$, $v'(0) = v'(T)$, $\sigma_1 \leqslant v \leqslant \sigma_2$ *on* $[0,T]$ *and, for a.e.* $t \in [0,T]$,

$$\begin{cases} \varepsilon_1\bigl(\phi\bigl(v'(t)\bigr)\bigr)' \leqslant \bigl(\psi(t) + v'(t)\bigr)\omega\bigl(\phi\bigl(v'(t)\bigr)\bigr) & \text{if } v'(t) > 0, \\ \varepsilon_2\bigl(\phi\bigl(v'(t)\bigr)\bigr)' \leqslant \bigl(\psi(t) - v'(t)\bigr)\omega\bigl(\phi\bigl(v'(t)\bigr)\bigr) & \text{if } v'(t) < 0. \end{cases}$$

□

Lemma 5.6 provides also a crucial argument for the proof of existence of a solution even in the case that the given problem possesses lower and upper functions σ_1 and σ_2 which do not satisfy (5.16), i.e. if

$$\sigma_1(\tau) > \sigma_2(\tau) \quad \text{for some } \tau \in [0,T]. \tag{5.19}$$

In such a case, the following a priori estimate is available.

LEMMA 5.8. *Let* $\psi \in L_1[0,T]$. *Then there is* $r^* > 0$ *such that* (5.18) *holds for each* $v \in C^1[0,T]$ *fulfilling* $\phi(v') \in AC[0,T]$, $v(0) = v(T)$, $v'(0) = v'(T)$ *and* $(\phi(v'(t)))' > \psi(t)$ (*or* $(\phi(v'(t)))' < \psi(t)$) *for a.e.* $t \in [0,T]$.

PROOF. We will restrict ourselves to the case that $(\phi(v'(t)))' > \psi(t)$ for a.e. $t \in [0,T]$. (The other case can be proved by a similar argument.) By the proof of [129, Lemma 1.1], we can see that $\|w\|_\infty < \|\psi\|_1$ holds for each $w \in AC[0,T]$ such that $w(0) = w(T)$, $w(t_w) = 0$ for some $t_w \in (0,T)$ and $w'(t) > \psi(t)$ for a.e. $t \in [0,T]$. The assertion of the lemma follows by setting $w = \phi(v')$ and

$$r^* = \phi^{-1}\bigl(\|\psi\|_1\bigr). \tag{5.20}$$

□

The next lemma provides an existence principle which will be helpful later:

LEMMA 5.9. *Let* σ_1 *and* σ_2 *be a lower and an upper function of* (5.4), (5.2) *and let* (5.19) *be true. Furthermore, let there be* $m \in L_1[0,T]$ *such that*

$$h(t,x,y) > m(t) \ (\text{or } h(t,x,y) < m(t)) \quad \text{for a.e. } t \in [0,T] \text{ and all } x, y \in \mathbb{R}$$

and let $r^* > 0$ *be given by* (5.20), *where* $\psi = |m| + 2$. *Then problem* (5.4), (5.2) *has a solution u satisfying*

$$\|u'\|_\infty < r^* \tag{5.21}$$

and

$$\min\bigl\{\sigma_1(\tau_u), \sigma_2(\tau_u)\bigr\} \leqslant u(\tau_u) \leqslant \max\bigl\{\sigma_1(\tau_u), \sigma_2(\tau_u)\bigr\} \quad \text{for some } \tau_u \in [0,T]. \tag{5.22}$$

SKETCH OF THE PROOF. We follow the ideas of the proof of Theorem 3.2 in [127]. Assume, e.g., that $h(t,x,y) > m(t)$ for a.e. $t \in [0,T]$ and all $x, y \in \mathbb{R}$.

Step 1. *Construction of an auxiliary problem and the operator representation.*

Define $\psi(t)\colon = -(|m(t)| + 2)$ for a.e. $t \in [0,T]$, find $r^* > 0$ as in Lemma 5.8 and set $c^* = \|\sigma_1\|_\infty + \|\sigma_2\|_\infty + Tr^*$. Consider the auxiliary problem

$$\bigl(\phi(u')\bigr)' = \widetilde{f}(t,u,u'), \quad u(0) = u(T), \quad u'(0) = u'(T), \tag{5.23}$$

where

$$\widetilde{f}(t,x,y) = \begin{cases} -\bigl(|m(t)| + 1\bigr) & \text{if } x \leqslant -(c^*+1), \\ h(t,x,y) + (x + c^*)\bigl(|m(t)| + 1 + h(t,x,y)\bigr) & \\ & \text{if } -(c^*+1) < x < -c^*, \\ h(t,x,y) & \text{if } -c^* \leqslant x \leqslant c^*, \\ h(t,x,y) + (x - c^*)|m(t)| & \text{if } c^* < x < c^* + 1, \\ h(t,x,y) + |m(t)| & \text{if } x \geqslant c^* + 1. \end{cases}$$

We have

$$\begin{cases} \widetilde{f}(t,x,y) < 0 & \text{if } x \leqslant -(c^*+1), \\ \widetilde{f}(t,x,y) > 0 & \text{if } x \geqslant c^* + 1, \\ \widetilde{f}(t,x,y) = h(t,x,y) & \text{if } x \in [-c^*, c^*], \end{cases} \tag{5.24}$$

$$\widetilde{f}(t,x,y) > \psi(t) \quad \text{for a.e. } t \in [0,T] \text{ and all } x, y \in \mathbb{R} \tag{5.25}$$

and σ_1 and σ_2 are a lower and an upper function of (5.23). Moreover, $\sigma_3(t) \equiv -c^* - 2$ and $\sigma_4(t) \equiv c^* + 2$ form another pair of a lower and an upper function for (5.23) and

$$\sigma_3 < \min\{\sigma_1, \sigma_2\} \leqslant \max\{\sigma_1, \sigma_2\} < \sigma_4 \text{ on } [0,T].$$

Denote $\Omega_0 = \{u \in C^1[0,T]\colon \sigma_3 < u < \sigma_4 \text{ on } [0,T],\ \|u'\|_\infty < r^*\}$,

$$\Omega_1 = \bigl\{u \in \Omega_0\colon \sigma_3 < u < \sigma_2 \text{ on } [0,T]\bigr\},$$
$$\Omega_2 = \bigl\{u \in \Omega_0\colon \sigma_1 < u < \sigma_4 \text{ on } [0,T]\bigr\}$$

and $\Omega = \Omega_0 \setminus \overline{\Omega_1 \cup \Omega_2}$. By Lemma 5.5, problem (5.23) is equivalent to the operator equation $\widetilde{\mathcal{F}}(u) = u$ in $C^1[0,T]$, where $\widetilde{\mathcal{F}}(u) = u(0) + u'(0) - u'(T) + \mathcal{K}(\widetilde{\mathcal{N}}(u))$, $(\widetilde{\mathcal{N}}(u))(t) = \widetilde{f}(t, u(t), u'(t))$ and $\mathcal{K}\colon L_1[0,T] \to C^1[0,T]$ is given by (5.11). Clearly, $\widetilde{\mathcal{F}}(u) = \mathcal{F}(u)$ for $u \in C^1[0,T]$ such that $\|u\|_\infty \leqslant c^*$.

Step 2. *A priori estimates*. We show that

$$\|u'\|_\infty < r^* \quad \text{and} \quad \|u\|_\infty < c^*$$

is true for all $u \in \overline{\Omega}$ such that $\widetilde{\mathcal{F}}(u) = u$.

Step 3. *Existence of a solution to* (5.4), (5.2).

Let $\widetilde{\mathcal{F}}(u) = u$ and $u \in \partial\Omega$. By Step 3, we have $\mathcal{F}(u) = \widetilde{\mathcal{F}}(u) = u$ and u solves (5.4), (5.2). Let $\widetilde{\mathcal{F}}(u) \neq u$ on $\partial\Omega$. Then using Lemma 5.6 we get

$$\deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_0\bigr) = \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_1\bigr) = \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_2\bigr) = 1.$$

Furthermore, by (5.19), we have $\Omega_1 \cap \Omega_2 = \emptyset$. Therefore, due to the additive property of the degree,

$$\deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega\bigr) = \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_0\bigr) - \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_1\bigr) - \deg\bigl(\mathcal{I} - \widetilde{\mathcal{F}}, \Omega_2\bigr) = -1$$

which implies that $\widetilde{\mathcal{F}}$ has a fixed point $u \in \Omega$. It follows by Step 3 that $\|u\|_\infty < c^*$ which, by virtue of (5.24), means that u solves (5.4), (5.2).

We can proceed analogously when $h(t, x, y) < m(t)$ for a.e. $t \in [0, T]$ and all $x, y \in \mathbb{R}$. □

5.2. *Method of lower and upper functions for singular problems*

Now, we consider problem (5.1), (5.2) where f satisfies (5.3). We present sufficient conditions in terms of lower and upper functions for the existence of positive solutions to (5.1), (5.2). Lower and upper functions σ_1 and σ_2 are defined in the same way as for the regular problem (5.4), (5.2) (see Definition 5.3). However, since problem (5.1), (5.2) is investigated on $[0, T] \times \mathcal{A}$ where $\mathcal{A} = [0, \infty) \times \mathbb{R}$, only such σ_1 and σ_2 which are positive a.e. on $[0, T]$ make sense.

The first existence result concerns problem (5.1), (5.2) having well-ordered lower and upper functions.

THEOREM 5.10. *Let there exist lower and upper functions* σ_1 *and* σ_2 *of problem* (5.1), (5.2) *such that* (5.16) *is true and* $\sigma_1 > 0$ *on* $[0, T]$. *Furthermore, let for a.e.* $t \in [0, T]$ *and each* $(x, y) \in [\sigma_1(t), \sigma_2(t)] \times \mathbb{R}$ *the inequalities*

$$\begin{cases} \varepsilon_1 f(t, x, y) \leqslant \bigl(\psi(t) + y\bigr)\omega\bigl(\phi(y)\bigr) & \text{if } y > 0, \\ \varepsilon_2 f(t, x, y) \leqslant \bigl(\psi(t) - y\bigr)\omega\bigl(\phi(y)\bigr) & \text{if } y < 0 \end{cases} \tag{5.26}$$

hold with $\varepsilon_1, \varepsilon_2, \omega$ *and* ψ *satisfying* (5.17). *Then problem* (5.1), (5.2) *has a positive solution* u *such that*

$$\sigma_1 \leqslant u \leqslant \sigma_2 \quad \text{on } [0, T]. \tag{5.27}$$

PROOF. *Step* 1. *The case* $\sigma_1 < \sigma_2$.

Assume that $\sigma_1 < \sigma_2$ on $[0, T]$. Consider the auxiliary problem (5.4), (5.2) with $h(t, x, y) = f(t, \max\{\sigma_1(t), \min\{x, \sigma_2(t)\}, y)$ for a.e. $t \in [0, T]$ and $(x, y) \in \mathbb{R}^2$. Clearly, $h \in Car([0, T] \times \mathbb{R}^2)$ and $h(t, x, y) = f(t, x, y)$ if $x \in [\sigma_1(t), \sigma_2(t)]$. Further, σ_1 and σ_2 are a lower and an upper function of (5.4), (5.2). Choose an arbitrary continuous $\eta : \mathbb{R} \to [0, 1]$

and let v be an arbitrary solution of (5.13) fulfilling $\sigma_1 \leqslant v \leqslant \sigma_2$ on $[0, T]$. Since (5.26) is satisfied with h in place of f, we have for a.e. $t \in [0, T]$

$$\begin{aligned}\varepsilon_1\big(\phi\big(v'(t)\big)\big)' &= \varepsilon_1\eta\big(v'(t)\big)h\big(t, v(t), v'(t)\big)\\ &\leqslant \eta\big(v'(t)\big)\big(\psi(t) + v'(t)\big)\omega\big(\phi\big(v'(t)\big)\big)\\ &\leqslant \big(\psi(t) + v'(t)\big)\omega\big(\phi\big(v'(t)\big)\big) \quad \text{if } v'(t) > 0\end{aligned}$$

and

$$\varepsilon_2\big(\phi\big(v'(t)\big)\big)' \leqslant \big(\psi(t) - v'(t)\big)\omega\big(\phi\big(v'(t)\big)\big) \quad \text{if } v'(t) < 0.$$

Hence we can apply Lemma 5.7 to deduce that (5.14) is satisfied. Let $\mathcal{F}: C^1[0, T] \to C^1[0, T]$ and $\Omega = \Omega_{r^*}$ be defined by (5.12) and (5.15), respectively. Then there are two possibilities: either $\mathcal{F}$ has a fixed point $u \in \partial\Omega$ or $\mathcal{F}(u) \neq u$ on $\partial\Omega$.

(a) Let $\mathcal{F}(u) = u$ for some $u \in \partial\Omega$. In view of Lemma 5.5 and of the definition of h, it follows that u is a solution to (5.1), (5.2) fulfilling (5.27).

(b) If $\mathcal{F}(u) \neq u$ on $\partial\Omega$, then by Lemma 5.6 we have $\deg(\mathcal{I} - \mathcal{F}, \Omega) = 1$, which implies that $\mathcal{F}$ has a fixed point $u \in \Omega$. As in (a), this fixed point is a solution to (5.1), (5.2) fulfilling (5.27).

Step 2. *The case* $\sigma_1 \leqslant \sigma_2$.

For each $k \in \mathbb{N}$, the function $\widetilde{\sigma}_k = \sigma_2 + \frac{1}{k}$ is also an upper function of (5.4), (5.2) and $\sigma_1 < \widetilde{\sigma}_k$ on $[0, T]$. Hence, in the general case, when the strict inequality between σ_1 and σ_2 need not hold, we can use Step 1 to show that for each $k \in \mathbb{N}$ there exists a solution u_k to (5.4), (5.2) such that

$$u_k(t) \in \big[\sigma_1(t), \sigma_2(t) + \tfrac{1}{k}\big] \quad \text{for } t \in [0, T] \quad \text{and} \quad \|u_k'\|_\infty < \rho^*,$$

where $\rho^* > 0$ is the a priori estimate given by Lemma 5.7 with $\sigma_2 + 1$ in place of σ_2. Using the Arzelà–Ascoli theorem and the Lebesgue dominated convergence theorem for the sequence $\{u_k\}$ we get a solution u of (5.1), (5.2) as the C^1-limit of a subsequence of $\{u_k\}$. □

REMARK 5.11. Theorem 5.10 provides the existence of a positive solution to problem (5.1), (5.2) with $f(t, x, y) = -h(x)y + g(t, x)$, if $h \in C[0, \infty)$, $g \in Car([0, T] \times (0, \infty))$ and if the existence of well-ordered and positive lower and upper functions is ensured. Indeed, for a.e. $t \in [0, T]$ and each $(x, y) \in [\sigma_1(t), \sigma_2(t)] \times \mathbb{R}$, we have

$$\big|f(t, x, y)\big| \leqslant \big|h(x)\big||y| + \big|g(t, x)\big| \leqslant K\big(\psi(t) + |y|\big)$$

where $K = 1 + \max\{|h(x)|\colon x \in [\delta, \|\sigma_2\|_\infty]\}$, $\psi(t) = \sup\{|g(t, x)|\colon x \in [\delta, \|\sigma_2\|_\infty]\}$ and $\delta = \min\{\sigma_1(t)\colon t \in [0, T]\}$. (By assumption, we have $\delta > 0$.)

Now, we will consider problem (5.1), (5.2) which has lower and upper functions, but no pair of them is well-ordered. We will deal with the periodic problem for the equation

$$\big(\phi(u')\big)' = g(u) + p(t, u, u'). \tag{5.28}$$

THEOREM 5.12. *Assume* $g \in C(0,\infty)$, $p \in Car([0,T]\times\mathbb{R}^2)$ *and*

$$\lim_{x\to 0+}\int_x^1 g(\xi)\,\mathrm{d}\xi = +\infty. \tag{5.29}$$

Let there exist lower and upper functions σ_1 *and* σ_2 *of problem* (5.28), (5.2) *such that* (5.19) *is true and* $\sigma_2 > 0$ *on* $[0,T]$. *Furthermore, let there exist an* $m \in L_1[0,T]$ *such that*

$$g(x) + p(t,x,y) > m(t) \quad \textit{for a.e. } t \in [0,T] \textit{ and all } x > 0,\ y \in \mathbb{R} \tag{5.30}$$

holds and let r^* *be given by* (5.20) *with* $\psi = |m| + 2$. *Then problem* (5.28), (5.2) *has a positive solution* u *satisfying* (5.21) *and* (5.22).

PROOF. We will use the ideas of [130]. Similarly to [130, Lemma 2.5] we can deduce from (5.29) and (5.30) that σ_1 is positive on $[0,T]$. Thus, $\delta := \min\{\{\sigma_1(t),\sigma_2(t)\}\colon\ t \in [0,T]\} > 0$. Put $R = \|\sigma_1\|_\infty + \|\sigma_2\|_\infty$ and $B = R + r^*T$. Furthermore, as $p \in Car([0,T]\times\mathbb{R}^2)$, there is $\widetilde{p} \in L_1[0,T]$ such that $|p(t,x,y)| \leqslant \widetilde{p}(t)$ for a.e. $t \in [0,T]$ and all $(x,y) \in [0,B]\times[-r^*,r^*]$. Put

$$K = \|\widetilde{p}\|_1 r^* + \int_\delta^B |g(\xi)|\,\mathrm{d}\xi.$$

By (5.29) there exists $\varepsilon \in (0,\delta)$ such that $g(\varepsilon) > 0$ and

$$\int_\varepsilon^\delta g(\xi)\,\mathrm{d}\xi > K. \tag{5.31}$$

For a.e. $t \in [0,T]$ and $(x,y) \in \mathbb{R}^2$, define

$$h(t,x,y) = \widetilde{g}(x) + p(t,x,y), \quad \text{where } \widetilde{g}(x) = \begin{cases} g(\varepsilon) & \text{if } x < \varepsilon,\\ g(x) & \text{if } x \geqslant \varepsilon.\end{cases}$$

Then $h \in Car([0,T]\times\mathbb{R}^2)$, σ_1 and σ_2 are lower and upper functions of (5.4), (5.2) and, by (5.30), $h(t,x,y) > m(t)$ for a.e. $t \in [0,T]$ and all $x > 0$, $y \in \mathbb{R}$. By Lemma 5.9, problem (5.4), (5.2) has a solution u satisfying (5.21) and $\delta \leqslant u(t_u) \leqslant R$ for some $t_u \in [0,T]$. In particular, $u \leqslant B$ for all $t \in [0,T]$. It remains to show that $u \geqslant \varepsilon$ on $[0,T]$.

Let $t_0, t_1 \in [0,T]$ be such that $u(t_0) = \min\{u(t)\colon\ t \in [0,T]\}$ and $u(t_1) = \max\{u(t)\colon\ t \in [0,T]\}$. We have $u'(t_0) = u'(t_1) = 0$ and $u(t_1) \in [\delta, B]$. Put $v(t) = \phi(u'(t))$ for $t \in [0,T]$. Then $u'(t) = \phi^{-1}(v(t))$ on $[0,T]$, $v(t_0) = v(t_1) = \phi(0)$ and

$$\int_{t_0}^{t_1} \bigl(\phi\bigl(u'(s)\bigr)\bigr)' u'(s)\,\mathrm{d}s = \int_{t_0}^{t_1} v'(s)\phi^{-1}\bigl(v(s)\bigr)\,\mathrm{d}s = \int_{v(t_0)}^{v(t_1)} \phi^{-1}(\xi)\,\mathrm{d}\xi = 0.$$

Thus, multiplying both sides of the equality $(\phi(u'(t)))' = h(t, u(t), u'(t))$ by $u'(t)$ and integrating from t_0 to t_1, we get

$$\int_{u(t_0)}^{u(t_1)} \widetilde{g}(\xi)\,\mathrm{d}\xi \leqslant \int_{t_0}^{t_1} \bigl|p\bigl(t, u(t), u'(t)\bigr)\bigr|\bigl|u'(t)\bigr|\,\mathrm{d}t \leqslant \|\widetilde{p}\|_1 r^*.$$

Therefore

$$\begin{aligned} g(\varepsilon)\bigl(\varepsilon - u(t_0)\bigr) + \int_{\varepsilon}^{\delta} g(\xi)\,\mathrm{d}\xi &= \int_{u(t_0)}^{\delta} \widetilde{g}(\xi)\,\mathrm{d}\xi \\ \leqslant \int_{u(t_0)}^{u(t_1)} \widetilde{g}(\xi)\,\mathrm{d}\xi + \int_{\delta}^{B} \bigl|g(\xi)\bigr|\,\mathrm{d}\xi &\leqslant \|\widetilde{p}\|_1 r^* + \int_{\delta}^{B} \bigl|g(\xi)\bigr|\,\mathrm{d}\xi = K. \end{aligned}$$

Since $g(\varepsilon) > 0$, this contradicts (5.31) whenever $u(t_0) = \min\{u(t)\colon t \in [0, T]\} < \varepsilon$. Hence, $u(t) \geqslant \varepsilon$ on $[0, T]$ which means that u is a solution to (5.28), (5.2). ☐

REMARK 5.13. Let g and p fulfill the assumptions of Theorem 5.12 and $f(t, x, y) = g(x) + p(t, x, y)$. Then the condition (5.29) implies that

$$\limsup_{x \to 0+} g(x) = +\infty, \tag{5.32}$$

which means by Remark 5.1 that f and g have a space repulsive singularity at $x = 0$. Each repulsive singularity having the property (5.29) is called a *strong singularity* of f and the corresponding function g is usually called a *strong repulsive singular force*. On the contrary, if (5.32) holds together with

$$\lim_{x \to 0+} \int_x^1 g(\xi)\,\mathrm{d}\xi \in \mathbb{R}, \tag{5.33}$$

then the singularity of f at $x = 0$ is called a *weak singularity* and g is called a *weak repulsive singular force.*

5.3. *Attractive singular forces*

This section is devoted to singular problem (5.1), (5.2) where f can have an attractive singularity at $x = 0$. (See Remark 5.1.)

In what follows we use the standard notation for mean values of integrable functions: for $y \in L_1[0, T]$, the symbol $\overline{y}$ stands for

$$\overline{y}\colon = \frac{1}{T} \int_0^T y(t)\,\mathrm{d}t.$$

THEOREM 5.14. *Let there exist* $r > 0$, $A > r$ *and* $b \in L_1[0,T]$ *such that* $\overline{b} \geqslant 0$,

$$f(t,r,0) \leqslant 0 \quad \textit{for a.e. } t \in [0,T], \tag{5.34}$$

$$f(t,x,y) \geqslant b(t)$$
$$\textit{for a.e. } t \in [0,T] \textit{ and all } x \in [A,B] \textit{ and } |y| \leqslant \phi^{-1}\big(\|b\|_1\big), \tag{5.35}$$

where

$$B - A \geqslant 2T\phi^{-1}\big(\|b\|_1\big). \tag{5.36}$$

Furthermore, let for a.e. $t \in [0,T]$ *and each* $(x,y) \in [r,B] \times \mathbb{R}$ *the inequalities* (5.26) *hold with* ε_1, ε_2, ω *and* ψ *satisfying* (5.17).

Then problem (5.1), (5.2) *has a positive solution* u *such that*

$$r \leqslant u \leqslant B \quad \textit{on } [0,T]. \tag{5.37}$$

PROOF. For a given $d \in \mathbb{R}$, let x_d be a solution of (5.9). Then

$$\phi\big(x_d'(t)\big) = \phi\big(x_d'(t_0)\big) + \int_{t_0}^{t} b(s)\,\mathrm{d}s \qquad \text{for all } t, t_0 \in [0,T].$$

Since $\overline{b} \geqslant 0$, it follows that $x_d'(T) \geqslant x_d'(0)$. Since $x_d(0) = x_d(T)$, there is a $t_d \in (0,T)$ such that $x_d'(t_d) = 0$. Thus

$$\phi\big(x_d'(t)\big) = \int_{t_d}^{t} b(s)\,\mathrm{d}s \quad \text{for } t \in [0,T]$$

and so $\|x_d'\|_\infty \leqslant \phi^{-1}(\|b\|_1)$ for each $d \in \mathbb{R}$ and $\|x_0\|_\infty \leqslant T\phi^{-1}(\|b\|_1)$. Put $\sigma_2 = A + T\phi^{-1}(\|b\|_1) + x_0$. Then

$$A \leqslant \sigma_2 \leqslant A + 2T\phi^{-1}\big(\|b\|_1\big) \leqslant B \qquad \text{on } [0,T]. \tag{5.38}$$

Having in mind (5.35) and (5.9), we can see that σ_2 is an upper function of (5.1), (5.2). Furthermore, $\sigma_1 = r$ is a lower function of problem (5.1), (5.2) and $0 < \sigma_1 < \sigma_2$ on $[0,T]$. By Theorem 5.10, problem (5.1), (5.2) has a positive solution u satisfying (5.37). □

Now, let us consider the Liénard periodic problem

$$\big(\phi(u')\big)' + h(u)u' = g(t,u) + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T), \tag{5.39}$$

where g can have an attractive space singularity at $x = 0$.

THEOREM 5.15. *Assume*

$$h \in C[0,\infty),\ e \in L_1[0,T],\ g \in Car\big([0,T]\times(0,\infty)\big), \tag{5.40}$$

$$\textit{there exists } \alpha > 0 \textit{ such that } \liminf_{|y|\to\infty} \frac{|\phi(y)|}{|y|^\alpha} > 0, \tag{5.41}$$

$$\begin{cases} \textit{there exists } r > 0 \textit{ such that} \\ g(t,r) + e(t) \leqslant 0 \quad \textit{for a.e. } t \in [0,T], \end{cases} \tag{5.42}$$

$$\begin{cases} \textit{there exist } A > r \textit{ and } g_0 \in L_1[0,T] \textit{ such that} \\ g(t,x) \geqslant g_0(t) \quad \textit{for a.e. } t \in [0,T] \textit{ and all } x \geqslant A \end{cases} \tag{5.43}$$

and

$$\overline{g}_0 + \overline{e} \geqslant 0. \tag{5.44}$$

Then problem (5.39) *has a positive solution u such that $u \geqslant r$ on* $[0,T]$.

SKETCH OF THE PROOF. We follow the ideas of the paper [128]. Define

$$f(t,x,y) = -h(x)y + g(t,x) + e(t)$$
$$\text{for a.e. } t \in [0,T] \text{ and all } x \in (0,\infty),\ y \in \mathbb{R}.$$

Step 1. First, notice that, due to (5.42), $\sigma_1(t) \equiv r$ is a lower function of (5.39).

Step 2. Thanks to (5.41), (5.43) and (5.44), we can construct an upper function σ_2 of (5.39). To this aim, take an arbitrary $C \in \mathbb{R}$ and consider a parameter auxiliary problem

$$\big(\phi(v')\big)' + \lambda h(v+C)v' = \lambda b(t), \quad v(0) = v(T) = 0, \quad \lambda \in [0,1], \tag{5.45}$$

where $b(t) = g_0(t) + e(t)$ for a.e. $t \in [0,T]$. By (5.41), there are $k > 0$ and $y_0 > 0$ such that

$$\big|\phi(y)\big| > \frac{k}{2}|y|^\alpha \quad \text{for } |y| \geqslant y_0. \tag{5.46}$$

Multiplying (5.45) by $v(t)$ and integrating over $[0,T]$, we obtain

$$-\int_0^T \phi\big(v'(t)\big)v'(t)\,\mathrm{d}t = \lambda\int_0^T b(t)v(t)\,\mathrm{d}t. \tag{5.47}$$

Using (5.46), (5.47) and the Hölder inequality, we can find $\rho \in (0,\infty)$, independent of $C \in \mathbb{R}$, such that $v \in \mathcal{B}(\rho) = \{x \in C^1[0,T]\colon \|x\|_\infty + \|x'\|_\infty < \rho\}$ holds for each $\lambda \in [0,1]$ and each solution v of (5.45). Thus, choosing a proper operator representation of problem (5.45) and using a standard homotopy and topological degree argument we can show that, for each $C \in \mathbb{R}$, problem (5.45) with $\lambda = 1$ has a solution $v_C \in \mathcal{B}(\rho)$. Now, it is already easy to see that if $C > A + \rho$, then $\sigma_2 = v_C + C$ is an upper function of (5.39). Indeed, we have $\sigma_2(0) = \sigma_2(T) = C$ and, due to (5.44),

$$\phi\big(\sigma_2'(T)\big) - \phi\big(\sigma_2'(0)\big) = T\overline{b} = T[\overline{g}_0 + \overline{e}] \geqslant 0.$$

Moreover, $\sigma_2(t) \geqslant C - \rho > A > r$ on $[0, T]$. Hence, by (5.43), we have

$$\begin{aligned}\big(\phi\big(\sigma_2'(t)\big)\big)' &= -h\big(\sigma_2(t)\big)\sigma_2'(t) + g_0(t) + e(t)\\ &\leqslant -h\big(\sigma_2(t)\big)\sigma_2'(t) + g\big(t, \sigma_2(t)\big) + e(t) = f\big(t, \sigma_2(t), \sigma_2'(t)\big)\\ &\qquad \text{for a.e. } t \in [0, T].\end{aligned}$$

Step 3. Finally, similarly as in Remark 5.11, we show that f satisfies (5.26) with $\omega(s) \equiv 1 + \max\{|h(x)|\colon x \in [r, \|\sigma_2\|_\infty]\}$, $\psi(t) = |e(t)| + \sup\{|g(t, x)|\colon x \in [r, \|\sigma_2\|_\infty]\}$ and $\varepsilon_1 = \varepsilon_2 = 1$. Therefore, by Theorem 5.10, problem (5.39) has a positive solution u such that $u \geqslant r$ on $[0, T]$. □

REMARK 5.16. If g does not depend on t, i.e. $g(t, x) \equiv g(x)$ for a.e. $t \in [0, T]$ and all $x \in (0, \infty)$, then the condition (5.42) is satisfied if $\liminf_{x\to 0+}(g(x) + \|e\|_\infty) < 0$ which is true, e.g., if $\liminf_{x\to 0+} g(x) = -\infty$ and $\sup\operatorname{ess}\{e(t)\colon t \in [0, T]\} < \infty$. Similarly, the conditions (5.43) and (5.44) are in such a case satisfied if $\liminf_{x\to\infty}(g(x) + \overline{e}) > 0$. In particular, Theorem 5.15 applies to problem (5.39) if $\phi = \phi_p$, $p > 1$, $\sup\operatorname{ess}\{e(t)\colon t \in [0, T]\} < \infty$, $\overline{e} > 0$, $g(t, x) = -\beta(t)x^{-\lambda}$, where $\beta \in L_1[0, T]$, $\beta \geqslant \varepsilon > 0$ a.e. on $[0, T]$ and $\lambda \geqslant 1$. Notice that the condition (5.41) is satisfied, e.g., by $\phi(y) = (|y|y + y)\ln(1 + \frac{1}{|y|})$ or $\phi(y) = y(\exp(y^2) - 1)$.

5.4. *Repulsive singular forces*

In this section we study the singular problem (5.1), (5.2) with f having a repulsive singularity at $x = 0$. Recall (see Remark 5.1) that this means that the relation

$$\limsup_{x\to 0+} f(t, x, y) = \infty \quad \text{for a.e. } t \in [0, T] \text{ and some } y \in \mathbb{R}$$

is true. In general, for the case of a repulsive singularity, the existence of a pair of associated lower and upper functions having opposite order is typical. This causes that such a case is more difficult and more interesting than that of an attractive singularity. The next assertion deals with equation (5.28) and is a direct corollary of Theorem 5.12.

THEOREM 5.17. *Assume* $g \in C(0, \infty)$, $p \in Car([0, T] \times \mathbb{R}^2)$, (5.29) *and* (5.30) *with some* $m \in L_1[0, T]$. *Furthermore, let there be* $r > 0$, $A > r$, $B \geqslant A$ *and* $b \in L_1[0, T]$ *such that* $\overline{b} \leqslant 0$, (5.36),

$$g(r) + p(t, r, 0) \geqslant 0 \quad \textit{for a.e. } t \in [0, T], \tag{5.48}$$

and

$$g(x) + p(t, x, y) \leqslant b(t) \quad \text{for a.e. } t \in [0, T] \text{ and all } x \in [A, B] \text{ and } |y| \leqslant \phi^{-1}\big(\|b\|_1\big) \tag{5.49}$$

hold. Then problem (5.28), (5.2) *has a positive solution u such that $u(t_u) \in [r, B]$ for some $t_u \in [0, T]$.*

PROOF. By (5.48), $\sigma_2(t) \equiv r$ is an upper function of (5.28), (5.2). Furthermore, let x_0 be a solution of

$$\big(\phi(x')\big)' = b(t), \quad u(0) = u(T) = 0.$$

Using (5.49) and having in mind that $\overline{b} \leqslant 0$, we can show by a reasoning analogous to that applied in the proof of Theorem 5.14 to construct an upper function that the function $\sigma_1 = A + T\phi^{-1}(\|b\|_1) + x_0$ is a lower function of (5.28), (5.2). Using Theorem 5.12 we complete the proof. □

In particular, when restricted to the Duffing equation with the ϕ-Laplacian

$$\big(\phi(u')\big)' = g(u) + e(t), \tag{5.50}$$

Theorem 5.17 has the following corollary.

COROLLARY 5.18. *Let $e \in L_1[0, T]$ with* $\operatorname{inf\,ess}\{e(t)\colon t \in [0, T]\} > -\infty$ *and let $g \in C(0, \infty)$ have a strong repulsive singularity* (5.29). *Further, let*

$$g_* := \inf\big\{g(x)\colon x \in (0, \infty)\big\} > -\infty \tag{5.51}$$

and let there be $A > 0$ such that

$$g(x) + \overline{e} \leqslant 0 \quad \text{for } x \in [A, B], \text{ where } B - A \geqslant 2T\phi^{-1}\big(\|e - \overline{e}\|_1\big).$$

Then problem (5.50), (5.2) *has a positive solution u such that $u(t_u) \leqslant B$ for some $t_u \in [0, T]$.*

PROOF. By (5.29) we have (5.32) and consequently there is an $r \in (0, A)$ such that $g(r) + e(t) \geqslant 0$ for a.e. $t \in [0, T]$. The assertion follows from Theorem 5.17 if we put $b(t) = e(t) - \overline{e}$ and $m(t) = g_* + e(t)$ a.e. on $[0, T]$. □

Consider the periodic problem for the Liénard equation

$$\big(\phi_p(u')\big)' + h(u)u' = g(u) + e(t) \tag{5.52}$$

with the p-Laplacian $\phi_p(y) = |y|^{p-2}y$. To this end, the following easy corollary of the continuation type principle due to Manásevich and Mawhin turned out to be essential.

LEMMA 5.19 [101, Theorem 3.1] and [84, Lemma 3]. *Let* $p > 1$, $h \in C[0,\infty)$, $g \in C(0,\infty)$ *and* $e \in L_1[0,T]$. *Furthermore, assume there exist* $r > 0$, $R > r$ *and* $R' > 0$ *such that*

(i) *the inequalities* $r < v < R$ *on* $[0,T]$ *and* $\|v'\|_\infty < R'$ *hold for each* $\lambda \in (0,1]$ *and for each positive solution* v *of the problem*

$$\begin{cases} \big(\phi_p(v')\big)' = \lambda\big(-h(v)v' + g(v) + e(t)\big), \\ v(0) = v(T), \quad v'(0) = v'(T), \end{cases} \tag{5.53}$$

(ii) $(g(x) + \overline{e} = 0) \Longrightarrow r < x < R$,

(iii) $(g(r) + \overline{e})(g(R) + \overline{e}) < 0$.

Then problem (5.52), (5.2) *has at least one solution* u *such that* $r < u < R$ *on* $[0,T]$.

Under the assumptions ensuring that g is bounded below on $(0,\infty)$, the following result was delivered by Jebelean and Mawhin.

THEOREM 5.20 [84, Theorem 2]. *Let* $p > 1$, $h \in C[0,\infty)$, $e \in L_1[0,T]$ *and let* $g \in C(0,\infty)$ *have a strong repulsive singularity* (5.29). *Furthermore, assume*

$$\liminf_{x\to\infty} g(x) > -\infty \tag{5.54}$$

and

$$\liminf_{x\to 0+}\big[g(x) + \overline{e}\big] > 0 > \limsup_{x\to\infty}\big[g(x) + \overline{e}\big]. \tag{5.55}$$

Then problem (5.52), (5.2) *has a positive solution.*

PROOF. We will verify that the assumptions of Lemma 5.19 are satisfied.

Step 1. First, we will show that

$$\begin{cases} \text{there are } R_0 > 0 \text{ and } R_1 > R_0 \text{ such that} \\ v(t_v) \in (R_0, R_1) \text{ for some } t_v \in [0,T] \\ \text{holds for each } \lambda \in (0,1] \text{ and each positive solution } v \text{ of (5.53).} \end{cases} \tag{5.56}$$

To this aim, assume that $\lambda \in (0,1]$ and that v is a positive solution to (5.53). Integrating the differential equation in (5.53) over $[0,T]$ and having in mind the periodicity of v, we get:

$$\int_0^T \big(g\big(v(t)\big) + e(t)\big)\,\mathrm{d}t = 0. \tag{5.57}$$

By the first inequality in (5.55), there is an $R_0 > 0$ such that

$$g(x) + \overline{e} > 0 \quad \text{whenever } x \in (0, R_0). \tag{5.58}$$

If $g(v(t)) + \overline{e} > 0$ were valid on $[0, T]$, we would have

$$\int_0^T \bigl(g\bigl(v(t)\bigr) + e(t)\bigr)\,\mathrm{d}t = \int_0^T \bigl(g\bigl(v(t)\bigr) + \overline{e}\bigr)\,\mathrm{d}t > 0.$$

Since this contradicts (5.57), we see that $\max\{v(t)\colon t \in [0, T]\} > R_0$. Similarly, by the second inequality in (5.55), there is an $R_1 > R_0$ such that $g(x) + \overline{e} < 0$ for $x \geqslant R_1$ and $v(t_1) < R_1$ for some $t_1 \in [0, T]$. Therefore (5.56) is true.

Step 2. Now we show that

$$\begin{cases} \text{there is } R > 0 \text{ such that } v < R \text{ on } [0, T] \\ \text{for each } \lambda \in (0, 1] \text{ and each positive solution } v \text{ of (5.53).} \end{cases} \tag{5.59}$$

Notice that, due to (5.54) and (5.58), we have $g_* = \inf\{g(x)\colon x \in (0, \infty)\} > -\infty$. Thus, multiplying (5.53) by v and integrating over $[0, T]$, we get

$$\|v'\|_p^p \leqslant \int_0^T \bigl(|g_*| + |e(t)|\bigr) v(t)\,\mathrm{d}t.$$

Furthermore, for R_1 given as in Step 1 and $\frac{1}{p} + \frac{1}{q} = 1$, we deduce that

$$\|v'\|_p^p \leqslant \left(\int_0^T \bigl(|g_*| + |e(t)|\bigr)\,\mathrm{d}t\right)\bigl(R_1 + T^{1/q}\|v'\|_p\bigr).$$

The right-hand side being a linear function of $\|v'\|_p$, this is possible only if there is $C_1 > 0$, independent of v and λ and such that $\|v'\|_p < C_1$. Therefore

$$v(t) = v(t_1) + \int_{t_1}^t v'(s)\,\mathrm{d}s < R_1 + T^{1/q} C_1$$

for all $\lambda \in (0, 1]$ and all positive solutions v of (5.53), i.e. the assertion (5.59) is true with $R := R_1 + T^{1/q} C_1$.

Step 3. Next we show that

$$\begin{cases} \text{there is } R_2 > 0 \text{ such that } |v'| < \lambda^{\frac{1}{p-1}} R_2 \text{ on } [0, T] \\ \text{for each } \lambda \in (0, 1] \text{ and each positive solution } v \text{ of (5.53).} \end{cases} \tag{5.60}$$

Having in mind that v satisfies the periodic conditions, we can see that there is $t' \in [0, T]$ such that $v'(t') = 0$. Integrating the differential equation in (5.53) over $[t', t]$ and taking into account (5.59), we get

$$\left|v'(t)\right|^{p-1} \leqslant \lambda\left(\int_0^R \left|h(x)\right| \mathrm{d}x + \|e\|_1 + \left|\int_{t'}^t \left|g\big(v(s)\big)\right| \mathrm{d}s\right|\right)$$
$$\text{for } t \in [0, T]. \tag{5.61}$$

By (5.58), there is $b > 0$ such that $g(x) \geqslant -b$ for all $x \in (0, R]$. So, by (5.59), $g(v(t)) \geqslant -b$ on $[0, T]$ holds for each possible positive solution v of (5.53). Therefore, $|g(v(t))| \leqslant g(v(t)) + 2b$ for all $t \in [0, T]$ wherefrom, using (5.57), we deduce

$$\left|\int_{t'}^t \left|g\big(v(s)\big)\right| \mathrm{d}s\right| \leqslant 2bT + \|e\|_1,$$

which inserted into (5.61) yields (5.60) with

$$R_2^{p-1} = \int_0^R \left|h(x)\right| \mathrm{d}x + 2\big(b + \|e\|_1\big) > 0.$$

Step 4. We show that

$$\begin{cases} \text{there is } r \in (0, R_0) \text{ such that } v > r \text{ on } [0, T] \\ \text{for each } \lambda \in (0, 1] \text{ and each positive solution } v \text{ of (5.53).} \end{cases} \tag{5.62}$$

Put $h_R := \max\{|h(x)|\colon\ x \in [0, R]\}$, $R^* = \frac{R_2^p}{q} + R_2(h_R R_2 T + \|e\|_1)$ and

$$K^* = R^* + \int_{R_0}^R \left|g(x)\right| \mathrm{d}x. \tag{5.63}$$

By (5.29), there is $r > 0$ such that

$$\int_r^{R_0} g(x)\,\mathrm{d}x > K^*. \tag{5.64}$$

Put $w(t) = \phi_p(v'(t))$ for $t \in [0, T]$. Then $|w(t)|^q = |v'(t)|^p$ for $t \in [0, T]$,

$$v'(t) = \left|w(t)\right|^{q-2} w(t) \quad \text{for } t \in [0, T] \tag{5.65}$$

and

$$w'(t) = \lambda\big(-h\big(v(t)\big)v'(t) + g\big(v(t)\big) + e(t)\big) \quad \text{for a.e. } t \in [0, T]. \tag{5.66}$$

Multiplying (5.65) by $w'(t)$ and (5.66) by $v'(t)$ and subtracting we get

$$\frac{1}{q}\big(|v'(t)|^p\big)' = \lambda\big(-h\big(v(t)\big)\big(v'(t)\big)^2 + g\big(v(t)\big)v'(t) + e(t)v'(t)\big)$$
$$\text{for a.e. } t \in [0,T]. \tag{5.67}$$

Now, suppose that $\min\{v(t)\colon\ t \in [0,T]\} < r$. Let us extend v to a T-periodic function on $\mathbb{R}$ and choose $t' \in [0,T]$ and $t^* \in (t', t'+T]$ so that $v(t') = r$, $v(t^*) = \max\{v(t)\colon\ t \in [0,T]\}$ and $v(t) \geqslant r$ on $[t', t^*]$. Integrating (5.67) from t' to t^*, we get

$$\lambda \int_r^{v(t^*)} g(x)\,\mathrm{d}x$$
$$= -\frac{1}{q}\big|v'(t')\big|^p - \lambda\bigg(\int_{t'}^{t^*} h\big(v(t)\big)\big(v'(t)\big)^2\,\mathrm{d}t + \int_{t'}^{t^*} e(t)v'(t)\,\mathrm{d}t\bigg).$$

Consequently, by (5.59) and (5.60),

$$\int_r^{v(t^*)} g(x)\,\mathrm{d}x \leqslant \frac{\lambda^{\frac{p}{p-1}}}{q} R_2^p + h_R \lambda^{\frac{2}{p-1}} R_2^2 T + \|e\|_1 \lambda^{\frac{1}{p-1}} R_2$$
$$\leqslant \frac{R_2^p}{q} + R_2\big(h_R R_2 T + \|e\|_1\big) = R^*,$$

which, by virtue of (5.63), finally gives

$$\int_r^{R_0} g(x)\,\mathrm{d}x = \int_r^{v(t^*)} g(x)\,\mathrm{d}x - \int_{R_0}^{v(t^*)} g(x)\,\mathrm{d}x \leqslant R^* + \int_{R_0}^{R} \big|g(x)\big|\,\mathrm{d}x = K^*.$$

This being contradictory to (5.64) implies that $v > r$ holds on $[0,T]$, i.e. (5.62) is true.

Step 5. To summarize, there are r, R and R' such that the assumption (i) from Lemma 5.19 is satisfied. Furthermore, since by Step 1 we have

$$g(x) + \overline{e} > 0 \quad \text{if } 0 < x < R_0 \quad \text{and} \quad g(x) + \overline{e} < 0 \quad \text{if } x > R_1$$

and $0 < r < R_0 < R_1 < R$, it is easy to see that also the assumptions (ii) and (iii) of Lemma 5.19 are satisfied. □

Assume that the dissipativity condition

$$h(x) \geqslant h_* > 0 \quad \text{or} \quad h(x) \leqslant -h_* < 0 \quad \text{for all } x \in [0,\infty) \tag{5.68}$$

is fulfilled instead of (5.54) and $e \in L_2[0,T]$. Then the existence of a positive solution to problem (5.52) is ensured by Jebelean and Mawhin.

THEOREM 5.21 [85, Theorem 3]. *Let* $p > 1$, $h \in C[0,\infty)$, $e \in L_2[0,T]$ *and let* $g \in C(0,\infty)$ *have a strong repulsive singularity* (5.29). *Furthermore, assume* (5.55) *and* (5.68). *Then problem* (5.52), (5.2) *has a positive solution.*

PROOF. The proof is analogous to that of Theorem 5.20, just the estimate (5.59) is, thanks to (5.68), obtained more easily. Indeed: let $\lambda \in (0,1]$ and let v be a positive solution of (5.53). Let R_0, R_1 and t_1 be found as in Step 1 of the proof of Theorem 5.20, i.e. R_0 is such that (5.58) is true, $R_1 > R_0$, $g(x) + \overline{e} < 0$ for $x \geqslant R_1$ and $v(t_1) < R_1$. Integrating equality (5.67) over $[0,T]$, we get $h_* \|v'\|_2 \leqslant \|e\|_2$ and, consequently,

$$v(t) = v(t_1) + \int_{t_1}^{t} v'(s)\,\mathrm{d}s < R_1 + \sqrt{T}\frac{\|e\|_2}{h_*} + 1 \quad \text{for all } t \in [0,T].$$

Thus, (5.59) is true with $R = R_1 + \sqrt{T}\frac{\|e\|_2}{h_*} + 1$. Now, we can repeat Steps 3–5 of the proof of Theorem 5.20. □

Lemma 5.19 enables us to prove also the following result concerning both the non-dissipative case and the case where g need not be bounded below on $(0,\infty)$. Recall that the symbol π_p is defined for $p > 1$ by

$$\pi_p = \frac{2\pi(p-1)^{1/p}}{p\sin(\frac{\pi}{p})}$$

and $(\frac{\pi_p}{T})^p$ is the first eigenvalue of the Dirichlet problem

$$\bigl(\phi_p(u')\bigr)' + \lambda\phi_p(u) = 0, \quad u(0) = u(T) = 0$$

(see [57]).

THEOREM 5.22. *Let* $p > 1$, $h \in C[0,\infty)$, $e \in L_1[0,T]$ *and let* $g \in C(0,\infty)$ *have a strong repulsive singularity* (5.29). *Furthermore, assume* (5.55) *and*

$$\begin{cases} \text{there exist } a,\ 0 \leqslant a < \bigl(\frac{\pi_p}{T}\bigr)^p, \text{ and } \gamma \geqslant 0 \text{ such that} \\ g(x)x \geqslant -\bigl(ax^p + \gamma\bigr) \quad \text{for all } x > 0. \end{cases} \tag{5.69}$$

Then problem (5.52), (5.2) *has a positive solution.*

PROOF. Similarly to the proof of Theorem 5.21, it suffices to verify (5.59). Assume that $\lambda \in (0,1]$, v is a positive solution to (5.53) and let R_1 and t_1 have the same meaning as in Step 1 of the proof of Theorem 5.20. Multiplying (5.53) by $v(t)$ and integrating over $[0,T]$, we get

$$\|v'\|_p^p \leqslant a\|v\|_p^p + \|e\|_1\|v\|_\infty + \gamma T. \tag{5.70}$$

Since $v(t_1) \leqslant R_1$, we have

$$0 < v(t) < R_1 + T^{1/q}\|v'\|_p \quad \text{for } t \in [0,T], \tag{5.71}$$

where $\frac{1}{p}+\frac{1}{q}=1$. Now put

$$y(t)=\begin{cases} v(t+t_1)-v(t_1) & \text{if } 0\leqslant t\leqslant T-t_1, \\ v(t+t_1-T)-v(t_1) & \text{if } T-t_1\leqslant t\leqslant T. \end{cases}$$

We have $y\in C^1[0,T]$, $y(0)=y(T)=0$ and $\|y+v(t_1)\|_p^p=\|v\|_p^p$. Therefore, by the generalized Poincaré-Wirtinger inequality (see, e.g., [153, Lemma 3]),

$$\|y\|_p\leqslant\frac{T}{\pi_p}\|y'\|_p=\frac{T}{\pi_p}\|v'\|_p.$$

Hence, for an arbitrary $\varepsilon>0$, there is a $C_1>0$ such that

$$\|v\|_p^p\leqslant\bigl(\|y\|_p+v(t_1)T^{1/p}\bigr)^p\leqslant(1+\varepsilon)\left(\frac{T}{\pi_p}\right)^p\|v'\|_p^p+C_1.$$

Inserting this into (5.70), choosing $\varepsilon\in(0,\frac{1}{a}(\frac{\pi_p}{T})^p-1)$ and having in mind (5.71), we deduce that

$$\alpha\|v'\|_p^p\leqslant T^{1/q}\|e\|_1\|v'\|_p+C_2$$

for some $C_2>0$, where $\alpha=(1-a(1+\varepsilon)(\frac{T}{\pi_p})^p)>0$. However, this is possible only if there is $R_p\in(0,\infty)$, independent of λ and v, such that $\|v'\|_p<R_p$. Therefore $0<v(t)<R_1+T^{1/q}R_p+1$ on $[0,T]$ for all $\lambda\in(0,1]$ and all positive solutions v of (5.53), i.e. the assertion (5.59) is true with $R=R_1+T^{1/q}R_p+1$.

By virtue of (5.55), we can choose $b>0$ so that $\inf\{g(x)\colon x\in(0,R]\}\geqslant -b$. Thus, we can continue by Steps 3–5 of the proof of Theorem 5.20 to verify that the assumptions of Lemma 5.19 are satisfied. □

REMARK 5.23. Theorem 5.22 is a slightly modified scalar version of the result by Liu [98, Theorem 1].

In the undamped case of the Duffing type equation

$$\bigl(\phi_p(u')\bigr)'=g(u)+e(t), \tag{5.72}$$

condition (5.69) can be replaced by a related asymptotic condition. It is shown in the next theorem which has been proved for $p=2$ by Rachůnková and Tvrdý in [125, Theorem 3.1].

THEOREM 5.24. *Let* $p>1$, $\frac{1}{p}+\frac{1}{q}=1$, $g\in C(0,\infty)$ *and* $e\in L_q[0,T]$. *Furthermore, assume* (5.29),

$$\liminf_{x\to 0+} g(x)>-\infty, \tag{5.73}$$

$$\liminf_{x\to\infty} \frac{g(x)}{x^{p-1}} > -\left(\frac{\pi_p}{T}\right)^p. \tag{5.74}$$

Further, assume that there exist $r > 0$ *and* $A > r$ *such that the conditions*

$$g(r) + e(t) \geqslant 0 \quad \textit{for a.e. } t \in [0, T] \tag{5.75}$$

and

$$g(x) + \overline{e} \leqslant 0 \quad \textit{for } x \in [A, B], \tag{5.76}$$

where

$$B - A \leqslant 2T \|e - \overline{e}\|_1^{q-1}, \tag{5.77}$$

are satisfied. Then problem (5.72), (5.2) *has a positive solution* u *such that* $u(t_u) \in [r, B]$ *for some* $t_u \in [0, T]$.

PROOF. *Step* 1. *Lower and upper functions.*

By (5.75), $\sigma_2 \equiv r$ is an upper function of (5.72), (5.2). Let v be a solution of the quasilinear Dirichlet problem (5.9) with $b(t) = e(t) - \overline{e}$ a.e. on $[0, T]$ and $d = 0$ and let $\sigma_1 = A + T\phi_p^{-1}(\|e - \overline{e}\|_1) + v$ on $[0, T]$. Let us recall that $\phi_p^{-1} = \phi_q$. Hence $\phi_p^{-1}(\|e - \overline{e}\|_1) = \|e - \overline{e}\|_1^{q-1}$. Having in mind assumption (5.76), we can see, similarly to the proof of Theorem 5.17 (see also the proof of Theorem 5.14), that σ_1 is a lower function of (5.72), (5.2) and $\sigma_1(t) \in [A, B]$ for $t \in [0, T]$.

Step 2. *Construction of an auxiliary problem having a right-hand side bounded below.*

By (5.29) we have (5.32) and hence there is a sequence $\{\varepsilon_n\} \subset (0, r)$ such that

$$g(\varepsilon_n) > 0 \quad \text{for } n \in \mathbb{N}, \qquad \lim_{n\to\infty} \varepsilon_n = 0 \quad \text{and} \quad \lim_{n\to\infty} g(\varepsilon_n) = \infty. \tag{5.78}$$

For $n \in \mathbb{N}$ and $M \in \mathbb{R}$, $M > r$, define

$$g_{n,M}(x) = \begin{cases} 0 & \text{if } x < 0, \\ \frac{g(\varepsilon_n)}{\varepsilon_n^{p-1}} x^{p-1} & \text{if } x \in [0, \varepsilon_n], \\ g(x) & \text{if } x \in [\varepsilon_n, M], \\ g(M) & \text{if } x > M. \end{cases} \tag{5.79}$$

By (5.74), there are $\eta \in (0, (\frac{\pi_p}{T})^p)$ and $x_0 > 1$ such that

$$\frac{g(x)}{x^{p-1}} \geqslant -\left(\left(\frac{\pi_p}{T}\right)^p - \eta\right) \quad \text{for all } x \geqslant x_0.$$

Put

$$p(x) = \begin{cases} 0 & \text{if } x \leqslant 0, \\ \frac{g(x_0)}{x_0^{p-1}} x^{p-1} & \text{if } x \in (0, x_0), \\ g(x) & \text{if } x \geqslant x_0 \end{cases}$$

and $q_{n,M}(x) = g_{n,M}(x) - p(x)$ for $x \in \mathbb{R}$. By virtue of (5.73), there is $\gamma \geqslant 0$ such that $q_{n,M}(x) \geqslant -\gamma$ for all $x \in \mathbb{R}$, $n \in \mathbb{N}$ and $M > r$. Consequently, each function $\widetilde{g}(x) = g_{n,M}(x)$, $n \in \mathbb{N}$, $M > r$, satisfies the estimate

$$\widetilde{g}(x)x \geqslant -\left(\left(\frac{\pi_p}{T}\right)^p - \eta\right)|x|^p - \gamma|x| \quad \text{for all } x \in \mathbb{R}. \tag{5.80}$$

Step 3. *A priori estimates.*

Now, we will give uniform a priori estimates for solutions of periodic problems associated to the equations

$$\big(\phi_p(u')\big)' = \widetilde{g}(u) + e(t), \tag{5.81}$$

where $\widetilde{g}$ may be an arbitrary function satisfying the estimate (5.80). To this aim, we will prove the following assertion.

CLAIM. *Let* $\gamma \geqslant 0$ *and* $\eta \in (0, (\frac{\pi_p}{T})^p)$. *Then for any* $\delta > 0$, *there are* $R \geqslant \delta$ *and* $R' > 0$ *such that the estimates*

$$u \leqslant R \quad \textit{on } [0, T] \quad \textit{and} \quad \|u'\|_p \leqslant R' \tag{5.82}$$

hold whenever

$$\begin{cases} \widetilde{g} \in C(0,\infty) \textit{ fulfills } (5.80) \textit{ and } u \textit{ is a solution of } (5.81), (5.2) \\ \textit{such that } \min\{u(t)\colon\ t \in [0, T]\} \leqslant \delta. \end{cases} \tag{5.83}$$

PROOF OF CLAIM. We will follow ideas from the proof of [130, Lemma 2.4]. Suppose that for each $k \in \mathbb{N}$ there are $g_k \in C(0, \infty)$ and a solution u_k of

$$\big(\phi_p(u')\big)' = g_k(u) + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T) \tag{5.84}$$

such that

$$g_k(x)x \geqslant -\left(\left(\frac{\pi_p}{T}\right)^p - \eta\right)|x|^p - \gamma|x| \tag{5.85}$$

and

$$u_k(t_k) = \delta \quad \text{for some } t_k \in [0, T] \quad \text{and} \quad \max\{u_k(t)\colon\ t \in [0, T]\} > k. \tag{5.86}$$

In particular, we have

$$\lim_{k\to\infty} \max\bigl\{u_k(t)\colon\ t\in[0,T]\bigr\}=\infty. \tag{5.87}$$

Let us extend u_k and e to functions T-periodic on $\mathbb{R}$. We have

$$\bigl(\phi_p\bigl(u_k'(t)\bigr)\bigr)'=g_k\bigl(u_k(t)\bigr)+e(t)\quad \text{for a.e. } t\in\mathbb{R}.$$

Multiplying this equality by u_k, integrating from t_k to t_k+T and making use of (5.85), we obtain

$$\begin{aligned}\|u_k'\|_p^p&=-\int_{t_k}^{t_k+T} g_k\bigl(u_k(s)\bigr)u_k(s)\,\mathrm{d}s-\int_{t_k}^{t_k+T} e(s)u_k(s)\,\mathrm{d}s\\ &\leqslant\left(\left(\frac{\pi_p}{T}\right)^p-\eta\right)\|u_k\|_p^p+\gamma T^{1/q}\|u_k\|_p+\|e\|_q\|u_k\|_p.\end{aligned}$$

Let us set $v_k=u_k-\delta$. By (5.87) we have $\lim_{k\to\infty}\|v_k\|_\infty=\infty$. Therefore, applying the Hölder inequality we can conclude that

$$\lim_{k\to\infty}\|v_k'\|_p=\infty. \tag{5.88}$$

Furthermore, it is easy to verify that

$$\|v_k'\|_p^p\leqslant\left(\left(\frac{\pi_p}{T}\right)^p-\epsilon\right)\|v_k\|_p^p+a\|v_k\|_p+b \tag{5.89}$$

holds with some $\epsilon\in(0,(\frac{\pi_p}{T})^p)$ and a, $b\geqslant 0$ not depending on v_k. This, together with (5.88), gives

$$\lim_{k\to\infty}\|v_k\|_p=\infty. \tag{5.90}$$

Moreover, as $v_k(t_k)=v_k(t_k+T)=0$, we can apply the generalized Poincaré–Wirtinger inequality (see, e.g., [153, Lemma 3]) to get

$$\|v_k\|_p^p\leqslant\left(\frac{T}{\pi_p}\right)^p\|v_k'\|_p^p\quad \text{for each } k\in\mathbb{N}.$$

Hence the inequality (5.89) can be rewritten as

$$\left(\frac{\pi_p}{T}\right)^p\leqslant\frac{\|v_k'\|_p^p}{\|v_k\|_p^p}\leqslant\left(\frac{\pi_p}{T}\right)^p-\epsilon+\frac{a}{\|v_k\|_p^{p-1}}+\frac{b}{\|v_k\|_p^p}, \tag{5.91}$$

which, in view of (5.90), leads to a contradiction

$$\left(\frac{\pi_p}{T}\right)^p \leqslant \left(\frac{\pi_p}{T}\right)^p - \epsilon.$$

As a consequence, we can conclude that the sequences $\{\|v_k\|_\infty\}$ and $\{\|v_k\|_p\}$ are bounded. By (5.89), this implies that also the sequence $\{\|v_k'\|_p\}$ is bounded. In particular, there are $R \in [\delta, \infty)$ and $R' \in (0, \infty)$ such that $u \leqslant R$ and $\|u'\|_p \leqslant R'$ hold whenever (5.83) is true. This completes the proof of Claim.

Now, let $R > B$ and $R' > 0$ be constants given by Claim for $\delta = B$. Put

$$K = \int_A^R \left|g(x)\right| \mathrm{d}x + \|e\|_q R'.$$

It follows from (5.29) and (5.78) that we can choose $\varepsilon = \varepsilon_{n^*} \in \{\varepsilon_n\}$ such that

$$\int_\varepsilon^A g(x)\,\mathrm{d}x > K \quad \text{and} \quad g(\varepsilon) > 0. \tag{5.92}$$

By (5.73), there is $g_R \in \mathbb{R}$ such that

$$g(x) \geqslant g_R \quad \text{for } x \in (0, R]. \tag{5.93}$$

Define

$$\widetilde{g}(x) = g_{n^*,R}(x) \quad \text{for } x \in \mathbb{R} \tag{5.94}$$

and consider the regular periodic problem for the auxiliary equation

$$\left(\phi_p(u')\right)' = \widetilde{g}(u) + e(t). \tag{5.95}$$

Clearly, σ_1 and σ_2 are lower and upper functions of (5.95), (5.2) and $\widetilde{g}(x) + e(t) \geqslant g_R + e(t)$ for a.e. $t \in [0, T]$ and all $x \in \mathbb{R}$. Thus, by Lemma 5.9, problem (5.95), (5.2) possesses a solution u such that $u(t_u) \in [r, B]$ for some $t_u \in [0, T]$. In particular, $\min\{u(t)\colon t \in [0, T]\} \leqslant B$. Furthermore, by Step 2 it is easy to see that $\widetilde{g}$ satisfies the estimate (5.80). Thus, by Claim and by the definitions of R and R', the estimates (5.82) are true.

Step 4. *Existence of a solution to* (5.72), (5.2).

It remains to show that $u \geqslant \varepsilon$ on $[0, T]$. Let $t_0, t_1 \in [0, T]$ be such that

$$u(t_0) = \min\bigl\{u(t)\colon t \in [0, T]\bigr\} \quad \text{and} \quad u(t_1) = \max\bigl\{u(t)\colon t \in [0, T]\bigr\}.$$

Due to the periodicity of u, we have $u'(t_0) = u'(t_1) = 0$. Multiplying the equality $(\phi_p(u'(t)))' = \widetilde{g}(u(t)) + e(t)$ by $u'(t)$ and integrating, we get

$$\int_{u(t_0)}^{u(t_1)} \widetilde{g}(x)\,\mathrm{d}x \leqslant \|e\|_q R'.$$

Therefore,

$$\int_{u(t_0)}^{A} \widetilde{g}(x)\,\mathrm{d}x \leqslant \int_{A}^{R} \left|g(x)\right|\mathrm{d}x + \|e\|_q R' = K.$$

Let $u(t_0) < \varepsilon$. Then, by (5.92),

$$\begin{aligned}\int_{u(t_0)}^{A} \widetilde{g}(x)\,\mathrm{d}x &= \int_{u(t_0)}^{\varepsilon} \widetilde{g}(x)\,\mathrm{d}x + \int_{\varepsilon}^{A} g(x)\,\mathrm{d}x \\ &= g(\varepsilon)\bigl(\varepsilon - u(t_0)\bigr) + \int_{\varepsilon}^{A} g(x)\,\mathrm{d}x \\ &> \int_{\varepsilon}^{A} g(x)\,\mathrm{d}x > K,\end{aligned}$$

a contradiction. So $u(t) \geqslant \varepsilon$ on $[0, T]$, which together with (5.79), (5.82) and (5.94) yields that u is a solution of (5.72), (5.2). □

EXAMPLES. (i) Let $p > 1$, $h \in C[0, \infty)$, $\beta > 0$, $\alpha \geqslant 1$, $e \in L_1[0, T]$. Then, by Theorem 5.20, the problem

$$\bigl(|u'|^{p-2}u'\bigr)' + h(u)u' = \frac{\beta}{u^{\alpha}} + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T) \tag{5.96}$$

has a positive solution if $\overline{e} < 0$. Integrating both sides of the differential equation in (5.96) over $[0, T]$ and taking into account the positivity of $g(x) = \beta x^{-\alpha}$ on $(0, \infty)$, we can see that the condition $\overline{e} < 0$ is also necessary for the existence of a positive solution to (5.96).

(ii) Let $p > 1$, $c \neq 0$, $a > 1$, $\beta > 0$, $\alpha \geqslant 1$. Then, by Theorem 5.21, the problem

$$\bigl(|u'|^{p-2}u'\bigr)' + cu' = \frac{\beta}{u^{\alpha}} - a\exp(u) + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T)$$

has a solution for each $e \in L_2[0, T]$.

(iii) Let $p > 1$, $h \in C[0, \infty)$, $0 < a < (\frac{\pi_p}{T})^p$, $\beta > 0$ and $\alpha \geqslant 1$. Then, by Theorem 5.22, the problem

$$\bigl(|u'|^{p-2}u'\bigr)' + h(u)u' = -au^{p-1} + \frac{\beta}{u^{\alpha}} + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T)$$

has a positive solution for each $e \in L_1[0, T]$.

For the classical case $p = 2$, the following result due to Omari and Ye is known. Its proof combines the lower and upper functions method, the degree theory and connectedness arguments for some properly chosen truncated equations and a posteriori estimates.

THEOREM 5.25 [108, Theorem 1.2]. *Assume* $e \in L_\infty[0,T]$, (5.29), $\lim_{x\to 0+} g(x) = \infty$ *and*

$$\liminf_{x\to\infty} \frac{g(x)}{x} \geqslant -\left(\frac{\pi}{T}\right)^2 \quad \text{and} \quad \liminf_{x\to\infty} \frac{2G(x)}{x^2} > -\left(\frac{\pi}{T}\right)^2,$$

where

$$G(x) = \int_x^1 g(\xi)\,\mathrm{d}\xi \quad \text{for } x \in (0,\infty).$$

Then the problem $u'' + h(u)u' = g(u) + e(t)$, (5.2) *has a solution if and only if it possesses a lower function* $\sigma_1 \in AC^1[0,T]$.

Hitherto we have assumed the strong singularity condition (5.29). The next existence principle enables us to treat also problems with weak repulsive singularities. We shall restrict ourselves to the case that $\phi(y) \equiv y$ and f does not depend on u', i.e. we consider the equation

$$u'' = f(t,u), \tag{5.97}$$

where $f : [0,T] \times (0,\infty) \to \mathbb{R}$.

THEOREM 5.26. *Let* $f \in Car([0,T] \times (0,\infty))$, $r > 0$, $A \geqslant r$ *and let* $\mu \in L_1[0,T]$ *and* $\beta \in L_1[0,T]$ *be such that* $\mu(t) \geqslant 0$ *a.e. on* $[0,T]$, $\overline{\mu} > 0$,

$$\overline{\beta} \leqslant 0 \quad \text{and} \quad f(t,x) \leqslant \beta(t) \quad \text{for a.e. } t \in [0,T] \text{ and all } x \in [A,B] \tag{5.98}$$

and

$$f(t,x) \geqslant -\mu(t)(x-r) \quad \text{for a.e. } t \in [0,T] \text{ and all } x \in [r,B], \tag{5.99}$$

where

$$B - A \geqslant \frac{T^2}{2}\overline{m},$$

$$m(t) = \max\bigl\{\sup\bigl\{f(t,x)\colon\ x \in [r,A]\bigr\}, \beta(t), 0\bigr\} \quad \text{for a.e. } t \in [0,T]$$

and

$$\begin{cases} v \geqslant 0 \text{ on } [0,T] \text{ holds for each } v \in AC^1[0,T] \text{ such that} \\ v''(t) + \mu(t)v(t) \geqslant 0 \quad \text{for a.e. } t \in [0,T], \\ v(0) = v(T), \quad v'(0) = v'(T). \end{cases} \tag{5.100}$$

Then problem (5.97), (5.2) *has a positive solution* u *such that* $r \leqslant u \leqslant B$ *on* $[0,T]$.

PROOF. The proof follows the ideas of the proof of [129, Theorem 2.5]. First, assume that $\overline{\beta} < 0$.

Step 1. *Existence of a solution u to a certain auxiliary problem.*

Put

$$\widetilde{f}(t,x) = \begin{cases} f(t,r) - \mu(t)(x-r) & \text{if } x \leqslant r, \\ f(t,x) & \text{if } x \in [r,B], \\ f(t,B) & \text{if } x \geqslant B \end{cases} \tag{5.101}$$

and consider the problem

$$u'' = \widetilde{f}(t,u), \quad u(0) = u(T), \quad u'(0) = u'(T). \tag{5.102}$$

We have $\widetilde{f} \in Car([0,T] \times \mathbb{R})$. By (5.98), (5.99) and (5.101), the inequalities

$$\widetilde{f}(t,x) \leqslant \beta(t) \quad \text{if } x \geqslant A \tag{5.103}$$

and

$$\widetilde{f}(t,x) \geqslant -\mu(t)\min\{x-r, B-r\} \tag{5.104}$$

are valid for a.e. $t \in [0,T]$ and all $x \in \mathbb{R}$. In particular, $\widetilde{f}(t,x) \geqslant -\mu(t)(B-r)$. By (5.104), $\sigma_2 \equiv r$ is an upper function of (5.102). Further, let σ_0 be the solution of the Dirichlet problem $v'' = b$, $v(0) = v(T) = 0$, where $b(t) = \beta(t) - \overline{\beta}$ for a.e. $t \in [0,T]$, and let $\sigma_c(t) = c + \sigma_0(t)$ for $t \in [0,T]$ and $c \in \mathbb{R}$. Then $\sigma_c'' = b$ a.e. on $t \in [0,T]$ and $\sigma_c(0) = \sigma_c(T) = c$. Moreover, $\sigma_c'(T) - \sigma_c'(0) = T\overline{b} = 0$. Let us choose $c^* > 0$ so that $\sigma_1 := \sigma_{c^*} \geqslant A$ on $[0,T]$. Due to (5.103), where $\beta < b$ a.e. on $[0,T]$, we can see that σ_1 is a lower function of (5.102). Therefore, by Lemma 5.9, the regular problem (5.102) has a solution u such that $u(t_u) \geqslant r$ for some $t_u \in [0,T]$.

Step 2. *Lower estimate for u.*

We shall show that

$$u \geqslant r \quad \text{on } [0,T]. \tag{5.105}$$

Set $z = u - r$. By virtue of (5.99) and (5.101), we have

$$z''(t) + \mu(t)z(t) = u''(t) + \mu(t)z(t) = \widetilde{f}\big(t,u(t)\big) + \mu(t)\big(u(t) - r\big) \geqslant 0$$

for a.e. $t \in [0,T]$. By (5.100), it follows that $z(t) \geqslant 0$ on $[0,T]$, i.e. (5.105) is true.

Step 3. *Upper estimate for u.*

We shall show that

$$u \leqslant B \quad \text{on } [0,T]. \tag{5.106}$$

By the definition of m and by (5.101) and (5.103) we have

$$\widetilde{f}(t,x) \leqslant m(t) \quad \text{for a.e. } t \in [0,T] \text{ and all } x \geqslant r.$$

Hence, we can use Lemma 5.8 (see (5.20)) to get

$$\|u'\|_\infty \leqslant \|m\|_1 = T\,\overline{m}. \tag{5.107}$$

If $u \geqslant A$ were valid on $[0,T]$, then taking into account the periodicity of u' and (5.103), we would get

$$0 = \int_0^T \widetilde{f}\big(t,u(t)\big)\,\mathrm{d}t \leqslant \int_0^T \beta(t)\,\mathrm{d}t = T\overline{\beta} < 0,$$

a contradiction. Thus, there is $\tau \in [0,T]$ such that $u(\tau) < A$. Now, assume that $u(s) > A$ for some $s \in [0,T]$ and extend u to the function T-periodic on $\mathbb{R}$. There are s_1, s_2 and $s^* \in \mathbb{R}$ such that $s_1 < s^* < s_2$, $s_2 - s_1 < T$, $u(s_1) = u(s_2) = A$ and $u(s^*) = \max\{u(s)\colon s \in [0,T]\} > A$. In particular, due to (5.107),

$$2\big(u(s^*) - A\big) = \int_{s_1}^{s^*} u'(s)\,\mathrm{d}s + \int_{s_2}^{s^*} u'(s)\,\mathrm{d}s \leqslant T^2\overline{m},$$

wherefrom the estimate

$$u(t) - A \leqslant \frac{T^2}{2}\overline{m} \leqslant B - A \quad \text{on } [0,T]$$

follows. Consequently, (5.106) is true.

Step 4. *Conclusion: u is a solution to* (5.97)*,* (5.2).

The estimates (5.105) and (5.106) mean that $r \leqslant u \leqslant B$ holds on $[0,T]$. By (5.101), we conclude that u is a solution to (5.97), (5.2).

If $\overline{\beta} = 0$, we can approximate the solution to (5.1), (5.2) by solutions of the problems

$$u'' = \widetilde{f}_n(t,u), \quad u(0) = u(T), \quad u'(0) = u'(T),$$

where

$$\widetilde{f}_n(t,x) = \begin{cases} f(t,r) & \text{if } x \leqslant r, \\ f(t,x) & \text{if } x \in [r,A], \\ f(t,x) - \mu(t)\frac{1}{n}\frac{x-A}{x-A+1} & \text{if } x \in [A,B], \\ f(t,B) - \mu(t)\frac{1}{n}\frac{B-A}{B-A+1} & \text{if } x \geqslant B. \end{cases}$$

□

Recently, using the Krasnoselskii fixed point theorem, Torres proved for the Hill equation

$$u'' + \mu(t)u = g(t, u) \tag{5.108}$$

the existence result which is related to Theorem 5.26.

THEOREM 5.27 [144, Theorem 4.5]. *Let $\mu \in L_1[0, T]$ be such that the problem*

$$v'' + \mu(t)v = 0, \quad v(0) = v(T), \quad v'(0) = v'(T) \tag{5.109}$$

possesses the Green function $G(t, s)$ which is positive on $[0, T] \times [0, T]$. Moreover, assume that there is an $R > 0$ such that

$$g(t, x) \geqslant 0 \quad \textit{for all } x \in \left(0, \frac{M}{m}R\right] \quad \textit{and}$$

$$g(t, x) \leqslant \frac{1}{TM}x \quad \textit{for all } x \in \left[R, \frac{M}{m}R\right]$$

for a.e. $t \in [0, T]$, where

$$m = \min\bigl\{G(t, s)\colon\ t, s \in [0, T]\bigr\} \quad \textit{and} \quad M = \max\bigl\{G(t, s)\colon\ t, s \in [0, T]\bigr\}.$$

Then problem (5.108), (5.2) *has a positive solution.*

It is easy to check that the function $G(t, s) = \sin(\frac{\pi}{T}|t - s|)$, $t, s \in [0, T]$, is the Green function for $v'' + (\frac{\pi}{T})^2 v = 0$, $v(0) = v(T)$, $v'(0) = v'(T)$ and $G(t, s) \geqslant 0$ on $[0, T] \times [0, T]$. Hence, the statement (5.100) holds if $\mu(t) \equiv \mu_1 = (\frac{\pi}{T})^2$. Notice that $\mu_1 = (\frac{\pi}{T})^2$ is the first eigenvalue of the related Dirichlet problem and it is optimal in the sense that for $\mu(t) = \mu$ a.e. on $[0, T]$ and $\mu \in (\mu_1, 4\mu_1)$ the corresponding Green function of $v'' + \mu v = 0$, $v(0) = v(T)$, $v'(0) = v'(T)$ is not nonnegative on $[0, T] \times [0, T]$.

In particular, when restricted to the Duffing equation

$$u'' = g(u) + e(t), \tag{5.110}$$

Theorem 5.26 has the following corollary.

COROLLARY 5.28 [129, Corollary 3.7]. *Suppose that $g \in C(0, \infty)$, $e \in L_1[0, T]$,*

$$\overline{e} + \limsup_{x \to \infty} g(x) < 0$$

and there is $r > 0$ such that

$$e(t) + g(x) + \left(\frac{\pi}{T}\right)^2 x \geqslant \left(\frac{\pi}{T}\right)^2 r \quad \textit{for a.e. } t \in [0, T] \textit{ and all } x > r.$$

Then problem (5.110), (5.2) *has a positive solution* u *such that* $u \geqslant r$ *on* $[0, T]$.

More detailed information on the sign properties of the associated Green functions is provided by the next proposition which is due to Torres [144] (see also [154, Lemma 2.5]). Before formulating it, let us define the function $K : [0, \infty] \to (0, \infty)$ by

$$K(z) = \begin{cases} \dfrac{2\pi}{zT^{1+2/z}}\left(\dfrac{2}{2+z}\right)^{1-2/z}\left(\dfrac{\Gamma(\frac{1}{z})}{\Gamma(\frac{1}{2}+\frac{1}{z})}\right)^2 & \text{if } 1 \leqslant z < \infty, \\ \dfrac{4}{T} & \text{if } z = \infty. \end{cases} \tag{5.111}$$

Let us recall that for a given z, $1 \leqslant z \leqslant \infty$, $K(z)$ is the best Sobolev constant for the inequality $C\|u\|_z^2 \leqslant \|u'\|_2^2$, i.e.

$$K(z) = \inf\left\{ \frac{\|u'\|_2^2}{\|u\|_z^2} \colon u \in H_0^1[0, T] \setminus \{0\} \right\},$$

where $H_0^1[0, T] = \{u \in AC[0, T] \colon u' \in L_2[0, T],\ u(0) = u(T) = 0\}$.

PROPOSITION 5.29 [144, Corollary 2.3]. *Let* $1 \leqslant q \leqslant \infty$ *and let* $\mu \in L_q[0, T]$. *Then* (5.100) *is true provided*

$$\mu(t) \geqslant 0 \quad \textit{a.e. on } [0, T], \quad \overline{\mu} > 0 \quad \textit{and} \quad \|\mu\|_q \leqslant K(2q^*), \tag{5.112}$$

where

$$\begin{cases} \frac{1}{q} + \frac{1}{q^*} = 1 & \textit{if } 1 < q < \infty, \\ q^* = \infty & \textit{if } q = 1, \\ q^* = 1 & \textit{if } q = \infty \end{cases} \tag{5.113}$$

and the function K *is defined by* (5.111).

Moreover, if $\|\mu\|_q < K(2q^*)$, *then problem* (5.109) *has the Green function which is positive on* $[0, T] \times [0, T]$.

Notice that if $\mu(t) \equiv \mu \in (0, \infty)$ on $[0, T]$, then we can take $q = \infty$, $q^* = 1$ and so we get $K(2q^*) = K(2) = (\frac{\pi}{T})^2$, which confirms the above mentioned fact that in such a case (5.100) is satisfied if $\mu \in (0, (\frac{\pi}{T})^2]$.

EXAMPLE. Consider the Brillouin beam focusing equation

$$u'' + a(1 + \cos t)u = \frac{1}{u} \tag{5.114}$$

on the interval $[0, 2\pi]$, where $a > 0$ is a parameter. (See [34] for a description of the model.) The problem of existence of a positive 2π-periodic solution to (5.114) has been considered by several authors (see, e.g., [55,144,145,152,154]). Put $A = \frac{1}{\sqrt{a}}$. Then for all $x \geqslant A$ and $t \in [0, 2\pi]$ we have

$$f(t, x) := \frac{1}{x} - a(1 + \cos t)x \leqslant \beta(t) := \frac{1}{A} - a(1 + \cos t)A$$

and $\overline{\beta} = \frac{1}{A} - aA = 0$. So, the assumption (5.98) is satisfied with $B = \infty$ and $T = 2\pi$. Furthermore, for $r \in (0, r_0]$ and a.e. $t \in [0, T]$ define

$$m_r(t) := \max\bigl\{\sup\bigl\{f(t, x)\colon\ x \in [r, A]\bigr\}, \beta(t), 0\bigr\}.$$

Let $r_0 = \frac{1}{\sqrt{2a}}$. Then $\frac{1}{r} - a(1 + \cos t)r \geqslant \frac{1}{r_0} - 2ar_0 = 0$ holds for $r \in (0, r_0]$ and $t \in [0, T]$. Consequently,

$$m_r(t) = \frac{1}{r} - a(1 + \cos t)r \quad \text{for a.e. } t \in [0, T] \text{ and all } r \in (0, r_0].$$

For a given $r \in (0, r_0]$, put $B_r = A + \pi\overline{m_r}$. Now, it is easy to check that it is possible to find $r \in (0, r_0]$ such that the assumption (5.99) is satisfied with $B = B_r$ and $\mu(t) = a(1 + \cos t)$ whenever $a < \frac{1}{2\pi} \approx 0.15915$. Finally, notice that by virtue of Proposition 5.29, the assumption (5.100) is satisfied if

$$a \leqslant K_{\max} := \max\left\{\frac{K(2q^*)}{\|1 + \cos t\|_q}\colon\ 1 \leqslant q \leqslant \infty\right\} \approx 0.16488.$$

(The maximum is attained at $q \approx 2.1941$, see [145, Corollary 4.8].) By Theorem 5.26, we can conclude that the equation (5.114) has a positive 2π-periodic solution for $a < \frac{1}{2\pi}$. To compare, notice that for $q = \infty$ and $T = 2\pi$, we get $q^* = 1$ and

$$\frac{K(2q^*)}{\|1 + \cos t\|_\infty} = \frac{1}{8} = 0.125.$$

Finally, let us note that using more sophisticated and involved techniques, Zhang proved (see [154, Theorem 4.5]) that for $a < K_{\max}$, $b > 0$, $\lambda \geqslant 1$, $e \in C[0, T]$ and $h \in C[0, \infty)$ the problem

$$u'' + h(u)u' + a(1 + \cos t)u = \frac{b}{u^\lambda} + e(t), \quad u(0) = u(2\pi), \quad u'(0) = u'(2\pi)$$

has a positive solution.

The hitherto mentioned conditions for the existence of a positive solution of problem (5.97), (5.2) concern the case when $f(t, x)$ asymptotically behaves like $-kx$ with $k \leqslant \mu_1$, $\mu_1 = (\frac{\pi}{T})^2$ being the first eigenvalue of the related Dirichlet problem. The next theorem deals with the case corresponding to k lying between two adjacent higher eigenvalues.

Let us denote by $\{\mu_k\}_{k=1}^{\infty}$ the sequence of eigenvalues of the related linear Dirichlet problem $u'' + \mu x = 0$, $u(0) = u(T) = 0$, that is,

$$\mu_k = \left(\frac{\pi k}{T}\right)^2, \quad k \in \mathbb{N}. \tag{5.115}$$

Furthermore, we set $\mu_0 = 0$.

THEOREM 5.30 [52, Theorem 1.1]. *Assume that $f : [0, T] \times (0, \infty) \to \mathbb{R}$ is continuous and there are positive constants c, c', δ and $\nu \geqslant 1$ such that*

$$\frac{c'}{x^\nu} \leqslant f(t, x) \leqslant \frac{c}{x^\nu} \quad \textit{for all } x \in (0, \delta). \tag{5.116}$$

Moreover, let there exist a nonnegative integer k such that

$$-\mu_{k+1} < \liminf_{x\to\infty} \frac{f(t, x)}{x} \leqslant \limsup_{x\to\infty} \frac{f(t, x)}{x} < -\mu_k$$
$$\textit{uniformly in } t \in [0, T]. \tag{5.117}$$

Then problem (5.97), (5.2) *has a positive solution.*

SKETCH OF THE PROOF. For a given $e \in C[0, T]$ denote by $\mathcal{R}(e)$ the unique solution of the problem

$$u'' + u = e(t), \quad u(0) = u(T), \quad u'(0) = u'(T).$$

It is known that $\mathcal{R}$ defines a compact linear operator on the space $C_T[0, T]$ of continuous T-periodic functions endowed with the sup norm $\|\cdot\|_\infty$. Problem (5.97), (5.2) is thus equivalent to finding a positive solution $u \in C_T[0, T]$ of the fixed point problem $u = \mathcal{T}(u)$, where

$$\mathcal{T}(u) = \mathcal{R}\big(u + f(\cdot, u)\big) \quad \text{for } u \in C_T[0, T].$$

For $0 < \varepsilon < M$ define $\Omega_{\varepsilon,M} = \{u \in C_T[0, T]\colon\ \varepsilon < u < M \text{ on } [0, T]\}$. Then $\mathcal{T} : \overline{\Omega}_{\varepsilon,M} \to C_T[0, T]$ is a completely continuous operator.

The proof of the theorem consists in showing that there are ε, M such that $\deg(\mathcal{I} - \mathcal{T}, \Omega_{\varepsilon,M}) \neq 0$:

Let k be from (5.117) and choose an arbitrary $\gamma \in (\mu_k, \mu_{k+1})$. Further, for $\lambda \in [0, 1]$ and $u \in C_T[0, T]$, define

$$\widetilde{\mathcal{T}}(u) = \mathcal{R}\left(\gamma u - \frac{1}{u^\nu} + u\right) \quad \text{and} \quad \mathcal{T}_\lambda(u) = \lambda\widetilde{\mathcal{T}}(u) + (1 - \lambda)\mathcal{T}(u).$$

Notice that

$$\mathcal{T}_\lambda(u) = \mathcal{R}\left(\lambda\left(\gamma u - \frac{1}{u^\nu}\right) + (1-\lambda) f(\cdot, u) + u\right).$$

Furthermore, $\mathcal{T}_0 = \mathcal{T}$ and $\mathcal{T}_1 = \widetilde{\mathcal{T}}$. It can be shown that there are ε, M such that $0 < \varepsilon < M$ and $u \neq \mathcal{T}_\lambda(u)$ for all $u \in \partial\Omega_{\varepsilon,M}$. By the homotopy property of the degree, it follows that $\deg(\mathcal{I} - \mathcal{T}, \Omega_{\varepsilon,M}) = \deg(\mathcal{I} - \widetilde{\mathcal{T}}, \Omega_{\varepsilon,M})$.

Define

$$\widetilde{\mathcal{S}}(u) = \mathcal{R}\left(\gamma u - \frac{\lambda}{u^3} + u\right) \quad \text{and} \quad \mathcal{S}_\lambda(u) = \lambda \widetilde{\mathcal{T}}(u) + (1-\lambda)\widetilde{\mathcal{S}}(u)$$

for $u \in C_T[0, T]$ and $\lambda \in [0, 1]$. We have

$$\mathcal{S}_\lambda(u) = \mathcal{R}\left(\gamma u + u - (1-\lambda)\frac{1}{u^\nu} - \lambda\frac{1}{u^3}\right),$$

$\mathcal{S}_0 = \widetilde{\mathcal{S}}$ and $\mathcal{S}_1 = \widetilde{\mathcal{T}}$. Now, we prove that $u \neq \mathcal{S}_\lambda(u)$ on $\partial\Omega_{\varepsilon,M}$ for each $\lambda \in [0, 1]$ and for some suitable ε and M. Similarly to Step 1, this yields that $\deg(\mathcal{I} - \widetilde{\mathcal{T}}, \Omega_{\varepsilon,M}) = \deg(\mathcal{I} - \widetilde{\mathcal{S}}, \Omega_{\varepsilon,M})$.

The proof is completed by proving that $\deg(\mathcal{I} - \widetilde{\mathcal{S}}, \Omega_{\varepsilon,M}) \neq 0$. □

REMARK 5.31. Consider the problem

$$u'' + ku = \frac{\beta}{u^\lambda} + e(t), \quad u(0) = u(T), \quad u'(0) = u'(T) \tag{5.118}$$

with $\lambda > 0$, $\beta > 0$ and $k \geqslant 0$. Denote

$$g(x) = \frac{\beta}{x^\lambda} - kx \quad \text{for } x > 0.$$

If $e \in L_1[0, T]$, $k = 0$ and $\lambda \geqslant 1$, i.e. the function g has a strong singularity at $x = 0$, then by [96, Theorem 3.12] problem (5.118) has a positive solution if and only if $\overline{e} < 0$ and, in the case $\lambda \in (0, 1)$, this condition need not ensure the existence of a positive solution to (5.118) (cf. [96, Theorem 4.1]). Further, if $e \in C[0, T]$ and $\lambda \geqslant 1$, then by Theorem 5.30, problem (5.118) has a positive solution whenever the condition

$$k \neq \left(n\frac{\pi}{T}\right)^2 \quad \text{for all } n \in \mathbb{N}$$

is satisfied. It is worth mentioning that the resonance case of $k = (\frac{\pi}{T})^2$ is covered neither by Theorem 5.30 nor by Theorem 5.25 even for the strong singularity $\lambda \geqslant 1$.

In comparison to these results, it should be pointed out that using Corollary 5.28, we can obtain existence results also for the cases $\lambda \in (0,1)$ and $k = (\frac{\pi}{T})^2$. In particular, for problem (5.118), with $e \in L_1[0,T]$ we get the existence of a positive solution in the following cases:

$$k = 0, \quad \bar{e} < 0 \quad \text{and} \quad \inf\operatorname{ess}\{e(t)\colon t \in [0,T]\} > -\left(\frac{\pi^2}{T^2\lambda\beta}\right)^{\frac{\lambda}{\lambda+1}}(\lambda+1)\beta$$

or

$$0 < k < \left(\frac{\pi}{T}\right)^2 \quad \text{and} \quad \inf\operatorname{ess}\{e(t)\colon t \in [0,T]\} > -\left(\frac{\pi^2 - T^2k}{T^2\lambda\beta}\right)^{\frac{\lambda}{\lambda+1}}(\lambda+1)\beta$$

or

$$k = \left(\frac{\pi}{T}\right)^2 \quad \text{and} \quad \inf\operatorname{ess}\{e(t)\colon t \in [0,T]\} > 0.$$

Notice that for the case $0 < k < (\frac{\pi}{T})^2$, Theorem 5.27 provides a complementary existence condition. For details, see [144, Corollary 4.6].

We close this section by mentioning some results concerning the case when the nonlinearity can have both a space singularity at $x = 0$ and superlinear descent for large x. The first is due to del Pino and Manásevich. It was motivated by [156], where an equation governing the nonlinear vibrations of a radially forced thick-walled and incompressible material was derived. The proof makes use of a version of the Poincaré–Birkhoff theorem due to Ding [56] together with an analysis of some oscillatory properties of solutions to the related initial value problems.

THEOREM 5.32 [51, Theorem 2.1]. *Let* $f : \mathbb{R} \times (0,\infty) \to \mathbb{R}$ *be continuous, locally Lipschitz in* x, T*-periodic in* t *and such that for* $s, \beta \in \mathbb{R}$ *and* $\alpha > 0$, *the solution* $u(t)$ *of the local initial value problem*

$$u'' = f(t,u), \quad u(s) = \alpha, \quad u'(s) = \beta$$

is continuable to the whole real line $\mathbb{R}$ *and* $u > 0$ *on* $\mathbb{R}$. *Furthermore, assume that*

$$0 < \liminf_{x\to 0+} xf(t,x) \leqslant \infty \quad \textit{and} \quad \lim_{x\to\infty} \frac{f(t,x)}{x} = -\infty$$

uniformly in t. *Then there is* $n_0 \in \mathbb{N}$ *such that for every* $n \geqslant n_0$ *there exist two distinct* T*-periodic positive solutions* u_{n1}, u_{n2} *of* (5.97), (5.2) *such that both* $u_{n1} - 1$ *and* $u_{n2} - 1$ *have exactly* $2n$ *zeros in* $[0,T)$. *In particular, problem* (5.97), (5.2) *possesses infinitely many* T*-periodic positive solutions.*

The other result is due to Ge and Mawhin. It deals with the equation

$$u'' = g(u) + p(t, u, u'). \tag{5.119}$$

Its proof was obtained by use of some continuation theorems valid in absence of a priori bounds and given by Capietto, Mawhin and Zanolin, e.g., in [46] and [103].

THEOREM 5.33 [73, Theorem 1]. *Let* $g \in C(0, \infty)$ *and* $p \in Car([0, T] \times \mathbb{R}^2)$. *Furthermore, assume that there are constants* $\alpha, \beta \geqslant 1$, $M \geqslant 0$, $L \geqslant 0$ *such that*

$$\lim_{x\to 0+} g(x)x^{\alpha} = \infty, \qquad \lim_{x\to\infty} \frac{g(x)}{x^{\beta}} = -\infty, \tag{5.120}$$

$$\left|p(t, x, y)\right| \leqslant \begin{cases} M\left(|x|^{\frac{1-\alpha}{2}} + |y|\right) + L & \textit{if } 0 < x < 1, \\ M\left(|x|^{\frac{1+\beta}{2}} + |y|\right) + L & \textit{if } x \geqslant 1. \end{cases} \tag{5.121}$$

Then problem (5.119), (5.2) *has a positive solution.*

5.5. *Historical and bibliographical notes*

In 1958 Bevc, Palmer and Süsskind [34] searched for positive 2π-periodic solutions of the Brillouin electron beam focusing system (5.114) which is a singular perturbation of the Mathieu equation. Before, in 1950, Pinney [113] considered the so-called Ermakov–Pinney equation $r'' + a(t)r = \frac{K}{r^3}$, where $a(t)$ is T-periodic and $K > 0$. Another example of the singular problem mentioned in literature are the parametric resonances of certain nonlinear Schrödinger systems (see [71]). As mentioned by Mawhin and Jebelean in their exhaustive historical introduction to the paper [84], second order nonlinear differential equations or systems with singularities appear naturally in the description of particles submitted to Newtonian type forces or to forces caused by compressed gases. Their mathematical study started in the sixties by Forbat and Huaux [69], Huaux [82], Derwidué [54] and Faure [65], who considered positive solutions of equations describing, e.g., the motion of a piston in a cylinder closed at one extremity and submitted to a T-periodic exterior force, to the restoring force of a perfect gas and to a viscosity friction. The equations under their study may be after suitable substitutions transformed to

$$u'' + cu' = \frac{\beta}{u} + e(t),$$

where $c \neq 0$ and $\beta \in \mathbb{R}$ can be either positive or negative. Equations of this form are usually called Forbat's equations and their Liénard type generalizations like

$$u'' + h(u)u' = g(t, u) + e(t) \tag{5.122}$$

are sometimes also referred to as the generalized Forbat's equations. It is worth mentioning that, while Forbat and others relied on the dissipativeness properties, Faure made use of the Leray–Schauder topological method.

Later, in the seventies, techniques of critical point theory were applied for the first time by Gordon [76], who also introduced the *strong force condition* of the type (5.29).

In 1988, Gaete and Manásevich [70], using variational methods, proved the existence of at least two different positive T-periodic solutions of the equation $u'' = p(t)u^2 - u + u^{-5}$ which governs the radial oscillations of an elastic spherical membrane made up of a neo-Hookean material, and subjected to an internal pressure $p : \mathbb{R} \to (0, \infty)$ continuous, T-periodic and non-constant.

In 1987, keeping in mind the model equation $u'' = \beta u^{-\lambda} + e(t)$ with $\lambda > 0$, $\beta \neq 0$ and $e \in L_1[0, T]$, Lazer and Solimini [96] employed topological arguments and the lower and upper functions method to investigate the existence of positive solutions to the Duffing equation $u'' = g(u) + e(t)$. The restoring force g was allowed to have an attractive singularity or a strong repulsive singularity at origin. Starting with this paper, the interest in periodic singular problems considerably increased. The results by Lazer and Solimini have been generalized or extended, e.g., by Habets and Sanchez [78] (1990), Mawhin [102] (1991), del Pino, Manásevich and Montero [52] (1992), del Pino and Manásevich [51] (1993), Fonda [66] (1993), Omari and Ye [108] (1995), Zhang [152] (1996) and [154] (1998) and Ge and Mawhin [73] (1998). Some of these papers (e.g., [78,108,152] or [154]) cover also the Liénard equation (5.122) with $g(t, x)$ having at $x = 0$ an essentially autonomous singularity. However, all of them, when dealing with the repulsive singularity, supposed that the strong force condition of the type (5.29) is satisfied. Furthermore, except for [51,52] and [73], they dealt with restoring forces $g(t, x)$ behaving at ∞ like $-kx$ with $0 < k < \mu_1$, $\mu_1 = (\frac{\pi}{T})^2$ being the first Dirichlet eigenvalue of $x'' + \mu x = 0$. The paper [52] was concerned with the cases corresponding to k lying between two adjacent higher eigenvalues, while the papers [51] and [73] dealt with the superlinear case. Recently, Yan and Zhang [151] (2003) proved an existence result assuming that the nonlinearity grows semilinearly as $x \to \infty$ and fulfill a certain higher-order non-resonance condition in terms of the periodic and antiperiodic eigenvalues. Let us mention also that Martinez-Amores and Torres [105] considered in 1996 stability of periodic solutions of problems with singularities of attractive type. Furthermore, in 1998, Torres [143] delivered results on the existence of bounded solutions to singular equations of repulsive type.

In 2001, Rachůnková, Tvrdý and Vrkoč [129], motivated by results on the existence of positive solutions to regular periodic problems by Nkashama and Santanilla [107] (1990) and Sanchez [131] (1992), made use of the lower and upper functions method to deliver related results in the form applicable also to singular problems. Unlike the above mentioned papers, their results concern also the resonance case $k = \mu_1$ and do not need any strong force condition. Later, in 2002, further step was done by Bonheure, Fonda and Smets [39] who made use of the properties of forced isochronous oscillators. Their results are also valid in the resonance case $k = \mu_1$ with a weak singularity. It turned out that in the resonance case $k = \mu_1$ problem (5.118) with $\lambda \geqslant 0$ has a solution whenever there is a $\delta > 0$ such that

$$\min_{t \in [0,T]} \int_t^{t+T} e(t) \sin\left(\pi \frac{s-t}{T}\right) \mathrm{d}s \geqslant \delta.$$

Analogous results were derived also by Bonheure and De Coster [38] in 2003 by means of the lower and upper functions method. Simultaneously, Torres [144] noticed that having a thorough analysis of the sign properties of the related Green's functions, solvability of the periodic problem with a weak singularity can be ensured also by the Krasnoselskii fixed point theorem. His results turned out to be complementary to those already known when $0 < k < \mu_1$.

For related multiplicity results we refer to the papers by Fonda, Manásevich and Zanolin [68] (1993), Rachůnková [115] and [116] (2000) and Rachůnková, Tvrdý and Vrkoč [130] (2003). In particular, in [115] an extension of the results of Gaete and Manásevich from [70] applicable to the equation modelling radial oscillations of an elastic spherical membrane can be found.

The regular periodic problem with ϕ- or p-Laplacian on the left-hand side was considered by several authors. For example, del Pino, Manásevich and Murúa [53] (1992) and Yan [150] (2003) proved the existence or multiplicity of periodic solutions of the equation $(\phi_p(u'))' = f(t,u)$ under non resonance conditions imposed on f. In 1998, general existence principles for the regular vector problem, based on the homotopy to the averaged nonlinearity, were presented by Manásevich and Mawhin [101] (1998) (see also Mawhin [104]). Multiplicity results were given by Liu in [97] (1998) and by Jiang, Chu and Zhang in [88] (2005). The resonance case was considered by Fabry and Fayyad in [61] (1992).

The first steps to establish the lower/upper functions method for problems with a ϕ-Laplacian operator on the left-hand side were done by Cabada and Pouso in [41] (1997) and by Jiang and Wang in [89] (1997), the latter paper dealing with the p-Laplacian. They assumed the existence of a pair of well-ordered lower and upper functions and both-sided Nagumo conditions. These results were extended by Staněk [133] (2001) to the case when a functional right-hand side fulfills one-sided growth conditions of Nagumo type. The paper by Cabada, Habets and Pouso [42] (1999) was the first to present the lower/upper functions method for periodic problems with a ϕ-Laplacian operator under the assumption that lower/upper functions are in the reverse order, see also [42] (2000). If $\phi = \phi_p$ the authors got the solvability for $1 < p \leqslant 2$ only. The general existence principle valid also when lower/upper functions are non-ordered was presented by Rachůnková and Tvrdý in [127] (2005) and for the case when impulses are admitted also in [126] (2005).

The singular periodic problem for the Liénard equation $(\phi_p(u'))' + h(u)u' = g(u) + e(t)$ with p-Laplacian on the left-hand side was treated by Liu [98] (2002) and Jebelean and Mawhin [84] (2002) and [85] (2004). Their main tool was the existence principle due to Manásevich and Mawhin from [101] (1998). Furthermore, in [84], the significance of the lower/upper functions method was shown.

The only existence results for problem (5.1), (5.2) with f having a singularity for $u' = 0$ were delivered by Staněk in [134] (2001) and [136] (2002).

Extensions to vector systems of the second order were not the subject of this text. We can only refer, e.g., to the papers by Habets and Sanchez [79] (1990), Solimini [132] (1990), Fonda [67] (1995) and Zhang [155] (1999) for the classical case and by Manásevich and Mawhin [101] (1998) and Liu [98] (2002) for systems with p-Laplacian operators on their left-hand sides.

6. Other types of two-point second order BVPs

In Sections 4 and 5, under the assumption that ϕ satisfies (3.3), we have investigated the nonlinear second order differential equation of the form

$$\big(\phi(u')\big)' + f(t,u,u') = 0, \tag{6.1}$$

subjected to Dirichlet and periodic boundary conditions, respectively. In this section we will study solvability of Eq. (6.1) with some other types of two-point boundary conditions on the interval $[0,T] \subset \mathbb{R}$.

We will focus our attention on problems with *space* or with *mixed* (*time and space*) singularities. According to Section 1, *solutions* and *w-solutions* of the problems are defined in the same way as for the Dirichlet problem (see Section 4.1) just replacing the Dirichlet conditions by the boundary conditions under consideration. We can define *lower and upper functions* of the second order boundary value problem in the same way as in Definition 4.3 replacing inequalities (4.6) with inequalities corresponding to the boundary conditions in question.

In the sequel we consider two-point linear boundary conditions arising in the study of physical, chemical or engineering problems and having the form

$$\begin{cases} a_0u(0) - b_0u'(0) = 0, \quad a_1u(T) + b_1u'(T) = 0, \\ a_i, b_i \in \mathbb{R}, \quad a_i^2 + b_i^2 > 0, \quad i = 0, 1. \end{cases} \tag{6.2}$$

Conditions (6.2) include conditions of the Dirichlet type (with $b_0 = b_1 = 0$), of the Neumann type (with $a_0 = a_1 = 0$), of the mixed type (with $a_0 = b_1 = 0$ or $b_0 = a_1 = 0$), of the Robin type (with $a_i > 0$, $b_i > 0$, $i = 0, 1$) and of the standard Sturm–Liouville type (with $a_i, b_i \in [0,\infty)$, $i = 0, 1$). We will also mention problems involving inhomogeneous form of the above boundary conditions, i.e.

$$\begin{cases} a_0u(0) - b_0u'(0) = A, \quad a_1u(T) + b_1u'(T) = B, \\ a_i, b_i \in \mathbb{R}, \quad a_i^2 + b_i^2 > 0, \quad i = 0, 1,\ A, B \in \mathbb{R}. \end{cases} \tag{6.3}$$

However, there is no restriction in assuming just the homogeneous conditions since a change from $u(t)$ to $y(t) = u(t) - q(t)$, where q is a polynomial satisfying (6.3), will reduce (6.3) to (6.2).

Consider a class of nonlinear singular boundary value problems whose importance is derived, in part, from the fact that they arise when searching for *positive, radially symmetric solutions* to the nonlinear elliptic partial differential equation

$$\Delta u + g(r,u) = 0 \quad \text{on } \Omega, \quad u\,|_\Gamma = 0,$$

where Δ is the Laplace operator, Ω is the open unit disk in $\mathbb{R}^n$ (centered at the origin), Γ is its boundary, and r is the radial distance from the origin. Radially symmetric solutions to this problem are solutions of the ordinary differential equation with the mixed boundary conditions

$$u'' + \frac{n-1}{t}u' + g(t,u) = 0, \quad u'(0) = 0, \quad u(1) = 0.$$

See, e.g., [29] or [74]. Particularly, Gatica, Oliker and Waltman [72] investigated the singular problem

$$u'' + \frac{n-1}{t}u' + \psi(t)\frac{1}{u^{\alpha}} = 0, \quad u'(0) = 0, \quad u(1) = 0, \tag{6.4}$$

where

$$\begin{cases} n \geqslant 2,\ \alpha \in (0,1),\ \psi \in C[0,1) \text{ is non-negative,} \\ \psi \text{ can have a time singularity at } t = 1. \end{cases} \tag{6.5}$$

THEOREM 6.1 [72, Theorem 4.1]. *Let* (6.5) *hold. Assume that*

$$0 < \int_0^1 (1-t)^{-\alpha}\psi(t)\,\mathrm{d}t < \infty.$$

Then problem (6.4) *has a solution that is positive on* [0, 1).

The technical arguments in the proof involve concavity of solutions and the use of iterative techniques. The main tool is a fixed point theorem for decreasing mappings on cones.

In the theory of diffusion and reaction a class of differential equations

$$u'' - \eta^2 g_\kappa(u) = 0 \tag{6.6}$$

appears. Here η^2 is the (positive) Thiele modulus, $u \geqslant 0$ is the concentration of one of the reactants and κ is a positive parameter. The functions g_κ are continuous on $[0,\infty)$,

$$\lim_{\kappa \to 0+} g_\kappa(x) = g(x) \quad \text{for } x \in (0,\infty)$$

and g can have a space singularity at $x = 0$. The model functions are

$$g_\kappa(x) = \frac{x}{\kappa + x^{1+\gamma}}, \tag{6.7}$$

where γ is a positive parameter. Aris [21] proposed such equations as descriptions of the steady state for chemicals reacting and diffusing according to the Langmuir–Hinshelwood kinetics. Bobisud [35] studied a class of equations (6.6) on $[-1,1]$ subjected to the inhomogeneous Robin boundary conditions

$$\alpha u(-1) - u'(-1) = A, \quad \alpha u(1) + u'(1) = A, \quad \alpha, A > 0, \tag{6.8}$$

and with functions g_κ behaving qualitatively very much like the model functions in (6.7). He proved that for η^2 in (6.6) sufficiently small the limit problem with $\kappa = 0$ has a positive solution which can be approximated uniformly on $[-1, 1]$ by solutions of (6.6), (6.8) with small κ.

Motivated by problem (6.6), (6.8) as well as by problem (6.4), Baxley and Gersdorff [27] studied a singular equation in which u' can appear nonlinearly,

$$u'' + h(t, u') - \eta^2 g(t, u) = 0, \quad \eta^2 > 0, \tag{6.9}$$

with inhomogeneous Sturm–Liouville boundary conditions

$$u'(0) = 0, \quad \alpha u(T) + \beta u'(T) = A, \quad \alpha, A > 0, \ \beta \geqslant 0, \tag{6.10}$$

where

$$\begin{cases} h \in C\big((0, T] \times [0, \infty)\big) \text{ is non-negative} \\ \text{and can have a time singularity at } t = 0, \end{cases} \tag{6.11}$$

$$\begin{cases} g \in C\big([0, T] \times \big(0, \frac{A}{\alpha}\big]\big) \text{ is positive} \\ \text{and can have a space singularity at } x = 0. \end{cases} \tag{6.12}$$

In contrast to Theorem 6.1 where positive singular nonlinearity $\psi(t)x^{-\alpha}$ appears, the next theorem applies to equations involving a negative singular term $-\eta^2 g(t, x)$.

THEOREM 6.2 [27, Theorem 17]. *Let* (6.11) *and* (6.12) *hold. Assume that*

$$h(t, 0) = 0 \quad \text{for } t \in (0, T]$$

and that there exists $G \in L[0, \frac{A}{\alpha}]$ *satisfying*

$$g(t, x) \leqslant G(x) \quad \text{on } [0, T] \times \big(0, \tfrac{A}{\alpha}\big]. \tag{6.13}$$

Then for η^2 *sufficiently small problem* (6.9), (6.10) *has a solution that is positive on* $[0, T]$.

Moreover, if η^2 is sufficiently large, Baxley and Gersdorff guarantee the existence of the so called *dead core* solutions which are defined as functions belonging for some $t_0 \in (0, T)$ to $C^1[0, T] \cap C^2(t_0, T]$, satisfying equation (6.9) on $(t_0, T]$, vanishing on $[0, t_0]$ and fulfilling (6.10). The proof is based on a priori estimates of approximate solutions of auxiliary regular problems and on the Arzelà–Ascoli theorem.

Agarwal, O'Regan and Staněk [15] considered a singular equation with a ϕ-Laplacian generalizing (6.9) and subjected to inhomogeneous mixed conditions

$$\big(\phi(u')\big)' - \mu f(t, u, u') = 0, \quad u'(0) = 0, \quad u(T) = b, \quad b > 0, \tag{6.14}$$

where μ is a real positive parameter and

$$\begin{cases} \phi(0)=0, \quad f \in Car\big([0,T]\times(\mathbb{R}\setminus\{b\})\times(\mathbb{R}\setminus\{0\})\big), \\ f \text{ can have space singularities at } x=b \text{ and } y=0. \end{cases} \tag{6.15}$$

THEOREM 6.3 [15, Theorem 3.1]. *Let* (6.15) *hold. Assume that there exist* $\varepsilon > 0$, $\nu \in (0,T]$ *and a positive non-decreasing function* $\rho \in C[0,T]$ *such that*

$$f\big(t,x,\rho(t)\big)=0 \quad \textit{for a.e. } t \in [0,T] \textit{ and all } x \in [0,b),$$

$$\varepsilon \leqslant f(t,x,y) \quad \textit{for a.e. } t \in [0,\nu] \textit{ and all } x \in [0,b),\ y \in [0,\nu].$$

Further, let for a.e. $t \in [0,T]$ *and for all* $x \in [0,b)$, $y \in (0,\rho(t)]$

$$0 \leqslant f(t,x,y) \leqslant \big(h_1(x)+h_2(x)\big)\big(\omega_1(y)+\omega_2(y)\big),$$

where $h_1 \in C[0,b]$, $\omega_1 \in C[0,\infty)$ *are non-negative*, $h_2 \in C[0,b)$, $\omega_2 \in C(0,\infty)$ *are positive*, h_1 *and* ω_2 *are non-increasing*, h_2 *and* ω_1 *are non-decreasing and* $\omega_1+\omega_2$ *is non-increasing on a right neighbourhood of* 0. *Moreover, let*

$$\int_0^b h_2(s)\,\mathrm{d}s < \infty, \qquad \int_0^1 \omega_2\big(\phi^{-1}(s)\big)\,\mathrm{d}s < \infty.$$

Finally, let there exist $\mu_* > 0$ *such that*

$$\int_0^b \frac{\mathrm{d}s}{\Omega^{-1}(\mu_* H(s))} = T, \tag{6.16}$$

where

$$H(u) = \int_0^u \big(h_1(s)+h_2(s)\big)\,\mathrm{d}s, \qquad \Omega(u) = \int_0^{\phi(u)} \frac{\phi^{-1}(s)\,\mathrm{d}s}{\omega_1(\phi^{-1}(s))+\omega_2(\phi^{-1}(s))}.$$

Then for each $\mu \in (0,\mu_*)$ *problem* (6.14) *has a solution u satisfying*

$$0 < u(t) \leqslant b, \quad 0 \leqslant u'(t) \leqslant \rho(t) \quad \textit{for } t \in [0,T].$$

To prove this existence result the authors used regularization and sequential techniques. First, they defined a family of auxiliary regular differential equations depending on $n \in \mathbb{N}$ and then, using the topological transversality theorem, they obtained a sequence of positive approximate solutions. Applying the Arzelà–Ascoli theorem and the Lebesgue convergence theorem they showed that its limit is a solution of problem (6.14).

REMARK 6.4. Note that if there exists $\mu_0 \in (0, \infty)$ such that

$$\int_0^b \frac{\mathrm{d}s}{\Omega^{-1}(\mu_0 H(s))} \in (T, \infty),$$

then $\mu_* \in (0, \mu_0)$ satisfying (6.16) can be always found.

Comparing problem (6.9), (6.10) and problem (6.14), they seem to be in some sense close, because both of them have negative singular nonlinearities in differential equations and the boundary conditions of (6.14) are contained in (6.10). However, there is a large difference between them. For example, positive solutions of (6.9), (6.10) do not touch the space singularity of f at $x = 0$. On the other hand, each solution u of (6.14) satisfies $u(T) = b$ and hence enters the space singularity of f at $x = b$. Another difference between them consists in the fact that f in (6.14) can have also a space singularity at $y = 0$ and hence Theorem 6.3 can be used in the following example whereas Theorem 6.2 cannot.

EXAMPLE. Let $\alpha \in (0, \infty)$ and $\beta \in (0, 1)$. By Theorem 6.3 there exists a positive number μ_* depending on β only such that for any $\mu \in (0, \mu_*)$ the problem

$$u'' - \mu\left(1 - |u|^\alpha\right)\left(\frac{1}{|u'|^\beta} - 1\right) = 0, \quad u'(0) = 0, \quad u(1) = \frac{1}{2},$$

has a solution u such that $0 < u(t) \leqslant \frac{1}{2}$, $0 \leqslant u'(t) \leqslant 1$ for $t \in [0, 1]$. An explicit formula for μ_* can be found in [15].

Assumption (6.13) in Theorem 6.2 means that the space singularity of g at $x = 0$ is a *weak singularity*. See Remark 5.1 for more detail. Note that the assumption (6.13) is not satisfied for the problem

$$u'' + \frac{t^2}{32u^2} - \frac{\lambda^2}{8} = 0, \quad u(0) = 0, \quad 2u'(1) - (1 - \nu)u(1) = 0, \tag{6.17}$$

where $\lambda \in (0, \infty)$, $\nu \in (0, 1)$, which models the large deflection membrane response of a spherical cap. This problem has been solved numerically by various techniques in engineering literature [75,106,111]. Baxley in [26] proved existence and uniqueness of a solution of this problem, gave qualitative information about the solution, and used this information to suggest an approach to numerical computation. In the proof the maximum principle plays a fundamental role. In contrast to (6.8), (6.11) and (6.14), problem (6.17) has boundary conditions which are not included in the Sturm–Liouville ones, because $\nu < 1$ and so the coefficient $-(1 - \nu)$ at $u(1)$ is negative.

Existence results for equations whose nonlinearities have a singularity at $x = 0$ and can be increasing for $x \to \infty$ are proved in [4], where Agarwal and O'Regan obtained the existence of a w-solution $u > 0$ on $(0, 1]$ of such equations with mixed boundary conditions. Their theorem can be applied for example to the problem

$$u'' + \left(\frac{1}{u^\alpha} + u^\beta + 1\right)\left(1 + (u')^3\right) = 0, \quad u'(0) = 0, \quad u(1) = 0, \tag{6.18}$$

with $\alpha \in (0,1)$, $\beta \geqslant 0$. We see that the nonlinearity

$$f(t,x,y) = \left(\frac{1}{x^\alpha} + x^\beta + 1\right)\bigl(1 + y^3\bigr) \tag{6.19}$$

has a weak space singularity at $x = 0$ and can be increasing for large x. If $\beta \in (0,1)$ the growth of f is sublinear. For $\beta = 1$ or $\beta > 1$ the growth of f is linear or superlinear, respectively.

In the investigation of singular problems (6.1), (6.2) or (6.1), (6.3), lower and upper functions of the corresponding regular problems can be a fruitful tool. See for example papers by Kannan and O'Regan in [90] or by Agarwal and Staněk in [17]. We will demonstrate the role of lower and upper functions on the following singular problem with mixed boundary conditions

$$u'' + f(t,u,u') = 0, \quad u'(0) = 0, \quad u(T) = 0, \tag{6.20}$$

where

$$\begin{cases} \mathcal{D} = (0,\infty) \times (-\infty,0), \quad f \in Car\bigl((0,T) \times \mathcal{D}\bigr), \\ f \text{ can have time singularities at } t = 0,\ t = T \\ \text{and space singularities at } x = 0,\ y = 0. \end{cases} \tag{6.21}$$

First, consider an auxiliary regular problem

$$u'' + h(t,u,u') = 0, \quad u'(0) = 0, \quad u(T) = 0, \tag{6.22}$$

where $h \in Car([0,T] \times \mathbb{R}^2)$.

DEFINITION 6.5. A function $\sigma \in C[0,T]$ is called *a lower function of* (6.22) if there exists a finite set $\Sigma \subset (0,T)$ such that $\sigma \in AC^1_{loc}([0,T] \setminus \Sigma)$, $\sigma'(\tau+), \sigma'(\tau-) \in \mathbb{R}$ for each $\tau \in \Sigma$,

$$\sigma''(t) + f\bigl(t,\sigma(t),\sigma'(t)\bigr) \geqslant 0 \quad \text{for a.e. } t \in [0,T], \tag{6.23}$$

$$\sigma'(0) \geqslant 0, \quad \sigma(T) \leqslant 0, \quad \sigma'(\tau-) < \sigma'(\tau+) \quad \text{for each } \tau \in \Sigma. \tag{6.24}$$

If the inequalities in (6.23) and (6.24) are reversed, then σ is called *an upper function of* (6.22).

In what follows we will need the classical lower and upper functions result for the mixed problem (6.22).

LEMMA 6.6 [93, Lemma 3.7]. *Let σ_1 and σ_2 be a lower and an upper function for problem* (6.22) *such that $\sigma_1 \leqslant \sigma_2$ on* $[0,T]$. *Assume also that there is a function $\psi \in L_1[0,T]$ such that*

$$\left|h(t,x,y)\right| \leqslant \psi(t) \quad \text{for a.e. } t \in [0,T],\ \text{all } x \in \left[\sigma_1(t), \sigma_2(t)\right],\ y \in \mathbb{R}. \tag{6.25}$$

Then problem (6.22) *has a solution $u \in AC^1[0,T]$ satisfying*

$$\sigma_1(t) \leqslant u(t) \leqslant \sigma_2(t) \quad \text{for } t \in [0,T]. \tag{6.26}$$

We will apply Lemma 6.6 to the singular mixed problem (6.20).

THEOREM 6.7 [117, Theorem 3.1]. *Let* (6.21) *hold. Assume that there exist $\varepsilon \in (0,1)$, $\nu \in (0,T)$, $c \in (\nu,\infty)$ such that*

$$f\bigl(t, c(T-t), -c\bigr) = 0 \quad \text{for a.e. } t \in [0,T], \tag{6.27}$$

$$0 \leqslant f(t,x,y)$$
$$\text{for a.e. } t \in [0,T],\ \text{and all } x \in \bigl(0, c(T-t)\bigr],\ y \in [-c,0), \tag{6.28}$$

$$\varepsilon \leqslant f(t,x,y)$$
$$\text{for a.e. } t \in [0,\nu],\ \text{and all } x \in \bigl(0, c(T-t)\bigr],\ y \in [-\nu,0). \tag{6.29}$$

Then problem (6.20) *has a solution $u \in AC^1[0,T]$ satisfying*

$$0 < u(t) \leqslant c(T-t), \quad -c \leqslant u'(t) < 0 \quad \text{for } t \in (0,T). \tag{6.30}$$

PROOF. Let $k \in \mathbb{N}$, $k \geqslant \frac{3}{T}$.

Step 1. *Approximate solutions.*

For $t \in [\frac{1}{k}, T - \frac{1}{k}]$, $x \in \mathbb{R}$ and $y \in \mathbb{R}$ put

$$\alpha_k(t,x) = \begin{cases} c(T-t) & \text{if } x > c(T-t), \\ x & \text{if } \frac{c}{k} \leqslant x \leqslant c(T-t), \\ \frac{c}{k} & \text{if } x < \frac{c}{k}, \end{cases}$$

$$\beta_k(y) = \begin{cases} -\frac{\varepsilon}{k} & \text{if } y > -\frac{\varepsilon}{k}, \\ y & \text{if } -c \leqslant y \leqslant -\frac{\varepsilon}{k}, \\ -c & \text{if } y < -c, \end{cases} \qquad \gamma(y) = \begin{cases} \varepsilon & \text{if } y \geqslant -\nu, \\ \varepsilon\frac{c+y}{c-\nu} & \text{if } -c < y < -\nu, \\ 0 & \text{if } y \leqslant -c. \end{cases}$$

For a.e. $t \in [0,T]$ and $x, y \in \mathbb{R}$ define

$$f_k(t,x,y) = \begin{cases} \gamma(y) & \text{if } t \in [0, \frac{1}{k}), \\ f\bigl(t, \alpha_k(t,x), \beta_k(y)\bigr) & \text{if } t \in [\frac{1}{k}, T - \frac{1}{k}], \\ 0 & \text{if } t \in (T - \frac{1}{k}, T]. \end{cases}$$

Then $f_k \in Car([0,T] \times \mathbb{R}^2)$ and there is $\psi_k \in L_1[0,T]$ such that

$$\bigl|f_k(t,x,y)\bigr| \leqslant \psi_k(t) \quad \text{for a.e. } t \in [0,T], \text{ all } x, y \in \mathbb{R}. \tag{6.31}$$

We have got an auxiliary regular problem

$$u'' + f_k(t,u,u') = 0, \quad u'(0) = 0, \quad u(T) = 0. \tag{6.32}$$

Conditions (6.27) and (6.28) yield

$$f_k\bigl(t, c(T-t), -c\bigr) = 0 \quad \text{and} \quad f_k(t,0,0) \geqslant 0 \quad \text{for a.e. } t \in [0,T].$$

Put $\sigma_1(t) = 0$, $\sigma_2(t) = c(T-t)$ for $t \in [0,T]$. Then σ_1 and σ_2 are a lower and an upper function of (6.32). Hence, by Lemma 6.6, problem (6.32) has a solution u_k and

$$0 \leqslant u_k(t) \leqslant c(T-t) \quad \text{on } [0,T]. \tag{6.33}$$

Step 2. *A priori estimates of approximate solutions.*

Since $u_k'(0) = 0$ and $f_k(t,x,y) \geqslant 0$ for a.e. $t \in [0,T]$ and all $x, y \in \mathbb{R}$, we get $u_k'(t) \leqslant 0$ on $[0,T]$. Condition (6.33) and $u_k(T) = 0$ give $u_k(T) - u_k(t) \geqslant -c(T-t)$, which yields $u_k'(T) \geqslant -c$. Since u_k' is nonincreasing on $[0,T]$, we have proved

$$-c \leqslant u_k'(t) \leqslant 0 \quad \text{on } [0,T]. \tag{6.34}$$

Due to $u_k'(0) = 0$, there is $t_k \in (0,T]$ such that

$$-\nu \leqslant u_k'(t) \leqslant 0 \quad \text{for } t \in [0,t_k].$$

If $t_k \geqslant \nu$, we get by (6.29)

$$u_k'(t) \leqslant -\varepsilon t \quad \text{for } t \in [0,\nu]. \tag{6.35}$$

Assume that $t_k < \nu$ and $u_k'(t) < -\nu$ for $t \in (t_k, \nu]$. Then

$$u_k'(t) \leqslant -\varepsilon t \quad \text{for } t \in [0,t_k].$$

Since $-\nu < -\varepsilon t$ for $t \in (t_k, \nu]$, we get (6.35) again. Integrating (6.35) over $[0,\nu]$ and using the concavity of u_k on $[0,T]$ we deduce that

$$\frac{\varepsilon \nu^2}{2T}(T-t) \leqslant u_k(t) \quad \text{on } [0,T]. \tag{6.36}$$

Step 3. *Convergence of a sequence of approximate solutions.*

Consider the sequence $\{u_k\}$. Choose an arbitrary compact interval $J \subset (0,T)$. By virtue of (6.33)–(6.36) there is $k_0 \in \mathbb{N}$ such that for each $k \in \mathbb{N}$, $k \geqslant k_0$,

$$\frac{c}{k_0} \leqslant u_k(t) \leqslant c(T-t), \quad -c \leqslant u_k'(t) \leqslant -\frac{\varepsilon}{k_0} \quad \text{on } J, \tag{6.37}$$

and hence there is $\psi \in L_1(J)$ such that

$$\bigl|f_k\bigl(t, u_k(t), u_k'(t)\bigr)\bigr| \leqslant \psi(t) \quad \text{for a.e. } t \in J. \tag{6.38}$$

Using conditions (6.33), (6.34), (6.38), the Arzelà–Ascoli theorem and the diagonalization principle, we can choose $u \in C[0,T] \cap C^1(0,T)$ and a subsequence of $\{u_k\}$ which we denote for the sake of simplicity in the same way such that

$$\begin{cases} \lim\limits_{k\to\infty} u_k = u \quad \text{uniformly on } [0,T], \\ \lim\limits_{k\to\infty} u_k' = u' \quad \text{locally uniformly on } (0,T). \end{cases} \tag{6.39}$$

Therefore we have $u(T) = 0$.

Step 4. *Convergence of the sequence of approximate problems.*

Choose an arbitrary $\xi \in (0,T)$ such that

$$f(\xi, \cdot, \cdot) \text{ is continuous on } (0,\infty) \times (-\infty, 0).$$

By (6.37) there exist a compact interval $J^* \subset (0,T)$ and $k_* \in \mathbb{N}$ such that $\xi \in J^*$ and for each $k \geqslant k_*$

$$u_k(\xi) > \frac{c}{k_*}, \quad u_k'(\xi) < -\frac{\varepsilon}{k_*}, \quad J^* \subset \left[\frac{1}{k}, T - \frac{1}{k}\right].$$

Therefore

$$f_k\bigl(\xi, u_k(\xi), u_k'(\xi)\bigr) = f\bigl(\xi, u_k(\xi), u_k'(\xi)\bigr)$$

and, due to (6.39),

$$\lim_{k\to\infty} f_k\bigl(t, u_k(t), u_k'(t)\bigr) = f\bigl(t, u(t), u'(t)\bigr) \quad \text{for a.e. } t \in (0,T). \tag{6.40}$$

Choose an arbitrary $t \in (0,T)$. Then there exists a compact interval $J \subset (0,T)$ such that (6.38) holds for all sufficiently large k. By virtue of (6.32) we get

$$u_k'\left(\frac{T}{2}\right) - u_k'(t) = \int_{T/2}^{t} f_k\bigl(s, u_k(s), u_k'(s)\bigr)\,\mathrm{d}s.$$

Letting $k \to \infty$ and using (6.38), (6.39), (6.40) and the Lebesgue convergence theorem on J, we get

$$u'\left(\frac{T}{2}\right) - u'(t) = \int_{T/2}^{t} f\big(s, u(s), u'(s)\big)\,\mathrm{d}s \quad \text{for each } t \in (0, T). \tag{6.41}$$

Therefore $u \in AC^1_{loc}(0, T)$ satisfies

$$u''(t) + f\big(t, u(t), u'(t)\big) = 0 \quad \text{for a.e. } t \in (0, T). \tag{6.42}$$

Further, according to (6.32) and (6.34) we have for each $k \geqslant \frac{3}{T}$

$$\int_0^T f_k\big(s, u_k(s), u_k'(s)\big)\,\mathrm{d}s = -u_k'(T) \leqslant c,$$

which together with (6.28), (6.33), (6.34) and (6.40) yields, by the Fatou lemma, that $f(t, u(t), u'(t)) \in L_1[0, T]$. Therefore, by (6.42), $u \in AC^1[0, T]$. Moreover, for each $k \geqslant \frac{3}{T}$ and $t \in (0, T)$

$$\begin{aligned} \left|u_k'(t)\right| \leqslant{}& \int_0^t \left|f_k\big(s, u_k(s), u_k'(s)\big) - f\big(s, u(s), u'(s)\big)\right|\mathrm{d}s \\ &+ \int_0^t \left|f\big(s, u(s), u'(s)\big)\right|\mathrm{d}s. \end{aligned}$$

Hence by (6.39) and (6.40) for each $\varepsilon > 0$ there exists $\delta > 0$ and for each $t \in (0, \delta)$ there exists $k_0 = k_0(\varepsilon, t) \in \mathbb{N}$ such that

$$\left|u'(t)\right| \leqslant \left|u'(t) - u_{k_0}'(t)\right| + \left|u_{k_0}'(t)\right| < \varepsilon.$$

It means that $u'(0) = \lim_{t\to 0+} u'(t) = 0$. We have proved that u is a solution of problem (6.20). ☐

EXAMPLE. Let $\alpha > 0$, $\beta \geqslant 0$ be arbitrary numbers. By Theorem 6.7 problem (6.18) has a solution $u \in AC^1[0, 1]$ satisfying

$$0 < u(t) \leqslant 1 - t, \quad -1 \leqslant u'(t) < 0 \quad \text{for } t \in (0, 1).$$

Note that Theorem 6.7 guarantees solvability of problem (6.18) even for the nonlinearity (6.19) having a strong space singularity ($\alpha \geqslant 1$) at $x = 0$.

Subject Index

μ-condensing map, 12
ϕ-Laplacian, 634
π_p, 689
σ-Ca-selectionable map, 47
σ-mLL-selectionable map, 47

absolute neighbourhood retract (ANR), 8, 77, 81
absolute retract (AR), 9
acyclic map, 11
acyclic set, 9, 14, 59
admissible homotopy, 10, 60
admissible map, 3, 10, 60
admissible pair, 10
age-structured models, 462
almost upper semicontinuous (a.u.s.c.) map, 47
amphiphilic, 183
ANR-space, 23
anti-periodic problem, 74, 76
anti-periodic solution, 73, 93, 95
attractive singularity, 669
attractors, 515
autonomous problem, 553

bifurcation diagram, 562, 571, 573, 578
bounded solution, 61, 69, 79
Brillouin equation, 700

C^k equivalent, 352, 353
Carathéodory conditions, 609
– L^1-, 209
– L^1-, 232
– L^p-, 258, 263
Carathéodory map, 12
Carathéodory selection, 13, 47, 87
Carathéodory solution, 3
Cauchy problem, 52
center, 362, 378–380, 385, 386, 392, 395, 397, 406, 407
center manifolds, 476, 483
classical solution, 3, 77
clipping, 189
coincidence point, 14
compact map, 11
compactly admissible homotopy, 11
comparison principles, 313, 314, 316, 320
computing the direction of bifurcation, 575
computing the location of bifurcation, 573
condensing admissible map, 11
condensing composition, 27
condensing homotopy in J_A, 29
condensing map, 12
conjugate problem, 624
continuation principle, 26, 28, 29, 685
continuous dependence, 465, 468, 499
continuous map, 10
continuum, 215, 217, 239, 241, 244, 245, 273, 280, 323, 324
contractible set, 9
control problem, 6
convex nonlinearities, 559
covering (topological) dimension, 49, 52
Crandall–Rabinowitz bifurcation theorem, 553
cubic-like nonlinearities, 568
curves of solutions, 549
cyclicity, 397, 400, 401, 405, 406, 409, 410
– at a periodic orbit, 401
– homoclinic, 400
– Hopf, 397, 400, 407, 422, 423
– Poincaré, 400
cyclicity k, 400

dead core solution, 710
delay adaptation, 450
derivative discontinuities, 533
detection curve, 412
detection function, 412

1. Introduction

Subject and goal

As it is clear from the title,

(i) the *subject* of this paper is the Hopf bifurcation occurring in dynamical systems admitting a certain group of symmetries;

(ii) the *method* to study the above phenomenon presented in this paper is based on the usage of the so-called twisted equivariant degree.

The *goal* of this paper is to explain why "(ii)" is an appropriate tool to attack "(i)".

To get an idea of what the Hopf bifurcation is about, consider the simplest system of ODEs

$$\dot{x} = Ax \quad (x \in \mathbb{R}^2), \tag{1}$$

where $A : \mathbb{R}^2 \to \mathbb{R}^2$ is a linear operator. Obviously, the origin is a stationary solution to (1), and it is a standard fact of any undergraduate course of ODEs that this system admits a non-constant periodic solution iff the characteristic equation $\det \Delta(\lambda) = 0$, where $\Delta(\lambda) := \lambda \,\mathrm{Id} - A$, has a pair of (conjugate) purely imaginary complex roots (in this case the origin is called a *center* for (1)).

Assume now that the system (1) is included into a one-parameter family of systems

$$\dot{x} = A(\alpha)x \quad (\alpha \in \mathbb{R},\ x \in \mathbb{R}^2), \tag{2}$$

where $A(\cdot) : \mathbb{R}^2 \to \mathbb{R}^2$ is a linear operator (smoothly) depending on α, $A(\alpha_o) = A$ for some 'critical' value α_o and $(\alpha_o, 0)$ is an *isolated* center for (2) (i.e. it is the only center for α close to α_o). If a pair of complex roots λ of the characteristic equation crosses (for $\alpha = \alpha_o$) the imaginary axis, then the stationary solution $(\alpha, 0)$ changes its stability which results in appearance of non-constant periodic solutions. This phenomenon is called the Hopf bifurcation in (2). Similarly, one can speak about the occurrence of the Hopf bifurcation in a one-parameter family of n-dimensional linear systems of ODEs for $n > 2$ (does not matter that the corresponding purely imaginary roots may have multiplicities greater than one).

Next, consider a (nonlinear) autonomous system of ODEs of the type

$$\dot{x} = f(\alpha, x) \quad (\alpha \in \mathbb{R},\ x \in V := \mathbb{R}^n), \tag{3}$$

where $f : \mathbb{R} \oplus V \to V$ is a continuously differentiable function satisfying the condition that $f(\alpha, 0) = 0$ for all $\alpha \in \mathbb{R}$. Clearly, $(\alpha, 0)$ is a stationary solution to (3) for all α. In this situation, a change of stability simply means that some of the complex roots λ of the characteristic equation $\det \Delta_{(\alpha,0)}(\lambda) = 0$, where $\Delta_{(\alpha,0)}(\lambda) := \lambda \,\mathrm{Id} - D_x f(\alpha, 0)$, cross (for $\alpha = \alpha_o$) the imaginary axis. In particular, this means the existence of a purely imaginary characteristic root $i\beta_o$ for $\alpha = \alpha_o$, which (by the implicit function theorem) is a *necessary* condition for the Hopf bifurcation (i.e. for the appearance of non-constant small amplitude periodic solutions). However, simple examples show that, in contrast to the linear case, this algebraic condition on the linearization is not enough, in general, for the occurrence of the Hopf bifurcation. Of course, this is not surprising: the classical Grobman–Hartman Theorem provides the local topological equivalence of an autonomous system to its linearization (near the origin) only under the assumption that the linearization matrix does not have eigenvalues on the imaginary axis. In particular, this means that studying the Hopf bifurcation phenomenon in parametrized families of *nonlinear* systems requires an additional *topological* argument.

A standard way of studying the Hopf bifurcation is the application of the Central Manifold theorem (allowing a two-dimensional reduction) and usage of the Poincaré section associated with the induced system (see [113] for a detailed exposition of this stream of ideas, see also [8,68]). However, this approach meets serious technical difficulties if the multiplicity of a purely imaginary characteristic root is greater than one. To overcome these and other technical difficulties, alternative methods were developed based on Lyapunov–Schmidt reduction, normal form techniques, integral averaging, etc. (cf. [33,34,64,111]). On the other hand, one should mention rational-valued homotopy invariants of “degree type” introduced by F.B. Fuller [57], E.N. Dancer [39] and E.N. Dancer and J.F. Toland [40, 42,41] as important tools to study the Hopf bifurcation phenomenon.

Observe that for many mathematical models of natural phenomena, very often, their closeness to the real world problems is reflected (on top of their non-linear character) in the presence of symmetries that are related to some physical or geometric regularities. For systems (3) this means: V is an (orthogonal) representation of a group Γ and f commutes with the Γ-action on V (i.e.

$$f(\alpha, \gamma x) = \gamma f(\alpha, x) \quad (\gamma \in \Gamma,\ x \in V), \tag{4}$$

in which case f is called Γ-equivariant (here Γ acts trivially on the parameter space)). In this way, we arrive at the following question: what is a link between symmetries of a system and symmetric properties of the actual dynamics? In the context relevant to our discussion, this question translates as the following *symmetric Hopf bifurcation problem*: how can one measure, predict and classify symmetric properties/minimal number of periodic solutions appearing as a result of the Hopf bifurcation?

It should be pointed out that in the symmetric setting, the characteristic roots almost always are not simple which causes significant difficulties for the application of the standard methods. To analyze the symmetric Hopf bifurcation problem, Golubitsky et al. (cf. [63, 65–67], see also [31,28,100,116,101,102,147]) suggested a method based on the Central Manifold/Lyapunov–Schmidt finite-dimensional reduction and further usage of a special singularity theory. On the other hand, if system (3) is Hamiltonian, one can use a wide spectrum of variational methods rooted in Morse theory/Lusternik–Schnirelman theory. Although very effective, these methods are not easy to use as they require a serious topological/analytical background. Also, when dealing with a concrete problem admitting a large group of symmetries, one would like to take advantage of using computer routines to handle a huge number of possible symmetry types of the bifurcating periodic solutions. From this viewpoint, it is not clear if the above methods are “open enough” to be computerized. It is our belief that the method presented in this paper is simple enough to be understood by applied mathematicians, and effective enough

(a) to be applied in a standard way to different types of symmetric dynamical systems,
(b) to provide a full topological information on the symmetric structure of the bifurcating branches of periodic solutions,
(c) to be transparent from the viewpoint of interpretation of its results, and
(d) "last but not least", to be completely computerized.

Topological degree approach

(i) *From Leray–Schauder degree to S^1-degree*. The Leray–Schauder degree theory proved itself as a powerful tool for the detection of single and multiple solutions in various types of differential equations. However, when dealing with the Hopf bifurcation phenomenon in autonomous systems through a functional analysis approach, it can only detect equilibria while it remains *blind* to non-constant periodic solutions. The reason for it can be easily explained: shifting the argument of periodic functions represents an S^1-action, which implies that finding periodic solutions to the associated operator equation constitutes an S^1-equivariant problem. By the obvious reason, the Leray–Schauder degree cannot "distinguish" between the zero-dimensional S^1-orbits ($=$ equilibria) and the one-dimensional ones ($=$ cycles), and one should look for a suitable S^1-equivariant homotopy invariant.

Speaking in a slightly more formal language, introduce the frequency β of the (unknown) periodic solution as an additional parameter and reformulate problem (3) as an operator equation in the first Sobolev space $W := H^1(S^1; V)$ as follows:

$$\mathfrak{F}(\alpha, \beta, u) = 0, \tag{5}$$

where $u \in W$, $\mathfrak{F} : \mathbb{R} \times \mathbb{R}_+ \times W \to W$ is given by

$$\mathfrak{F}(\alpha, \beta, u) := u - (L + K)^{-1}\left[Ku + \frac{1}{\beta} N_f\big(\alpha, j(u)\big)\right],$$

with $N_f(\alpha, u)(t) := f(\alpha, u(t))$, $K(u) := \frac{1}{2\pi}\int_0^{2\pi} u(s)\,\mathrm{d}s$ and $j : H^1(S^1; V) \to C(S^1, V)$ being a natural embedding into the space of continuous functions. Formula

$$(\mathrm{e}^{\mathrm{i}\tau} u)(t) := u(t + \tau) \quad (\mathrm{e}^{\mathrm{i}\tau} \in S^1,\ u \in W) \tag{6}$$

equips W with a structure of Hilbert S^1-representation and, moreover, $\mathfrak{F}$ is S^1-equivariant. Take $u \in W$, put

$$G_u := \{z \in S^1 \colon\ \mathrm{e}^{\mathrm{i}\tau} u = u\} \tag{7}$$

and call it a *symmetry* of u (commonly called the *isotropy* of u). It is easy to see that equilibria for (3) have the whole group S^1 as their symmetry, while for a non-constant periodic solution u, one has $G_u = \mathbb{Z}_l$ for some $l = 1, 2, \ldots$. Observe, by the way, that the presence of symmetry $\mathbb{Z}_l$ for a periodic solution u has a transparent geometric meaning: it clearly indicates that u is "l-folded". These simple observations suggest a natural candidate for the range of values of the "right" invariant responsible for the *existence* of non-constant periodic solutions (in particular, for the occurrence of (non-symmetric) Hopf bifurcation) – it should take its values in the free $\mathbb{Z}$-module generated by $\mathbb{Z}_l$, $l = 1, 2, \dots$, rather than in the ring $\mathbb{Z}$ (as the Leray–Schauder degree does). The corresponding construction (called S^1-degree) was suggested in [45,46] (see also Subsections 3.5 and 3.6 of the present paper for an axiomatic approach and [79,81] for a more general setting).

(ii) *From S^1-degree to twisted degree*. Let us make one more step assuming system (3) to be Γ-symmetric (cf. (4)). Put $G := \Gamma \times S^1$. Then, W is a Hilbert G-representation with the G-action given by (cf. (6))

$$\bigl((\gamma, \mathrm{e}^{\mathrm{i}\tau})u\bigr)(t) := \gamma u(t+\tau) \quad (\gamma \in \Gamma,\ \mathrm{e}^{\mathrm{i}\tau} \in S^1,\ u \in W).$$

Moreover, this time $\mathfrak{F}$ is G-equivariant. One can easily verify that the symmetries $G_u := \{g \in G\colon\ gu = u\}$ of non-constant periodic functions u are the so-called *φ-twisted l-folded* subgroups $K^{\varphi,l}$ of G given by

$$K^{\varphi,l} := \bigl\{(\gamma, z) \in K \times S^1\colon\ \varphi(\gamma) = z^l\bigr\}$$

for K being a subgroup of Γ, $\varphi : K \to S^1$ a homomorphism and $l = 1, 2, \dots$ (cf. (7)). We have now a complete parallelism with the previous situation: in the same way as the Leray–Schauder degree was not enough to establish the *existence* of non-constant periodic solutions to (3), the S^1-degree is not enough to *classify symmetries* of these solutions. Clearly, the right G-equivariant homotopy invariant should take its values in the $\mathbb{Z}$-module $A_1^t(G)$ generated by φ-twisted l-folded subgroups (more precisely, by their conjugacy classes). The *twisted G-equivariant degree* (in short, twisted degree) is a topological tool precisely needed for the above purpose.

Roughly speaking, the G-equivariant twisted degree is an object that is only slightly more complicated than the usual Leray–Schauder degree. It is a finite sequence of integers, indexed (for the convenience of the user) by the conjugacy classes (H) of φ-twisted l-folded subgroups H of G. To be more specific, given a group $G = \Gamma \times S^1$, an isometric Banach G-representation W, an open invariant subset $\Omega \subset \mathbb{R} \oplus W$ and a continuous G-equivariant map $f : (\overline{\Omega}, \partial\Omega) \to (W, W \setminus \{0\})$, one can assign to f the twisted G-equivariant degree in the following form:

$$G\text{-}\mathrm{Deg}^t(f, \Omega) = n_1(H_1) + n_2(H_2) + \cdots + n_k(H_k), \quad n_i \in \mathbb{Z}. \tag{8}$$

As we will see later on, $G\text{-}\mathrm{Deg}^t(f, \Omega)$ satisfies all the properties expected from any reasonable "degree theory", in particular, existence, homotopy invariance, excision, suspension, additivity, multiplicativity, etc. (adopted to the equivariant setting). Moreover, similarly to the Leray–Schauder degree, the twisted degree admits an axiomatic approach which allows applied mathematicians to use it without going into topological (homotopy theory, bordism theory) and analytical (equivariant transversality, normality) roots underlying its construction. Thus, it can be easily applied to equivariant settings in the same way as the Leray–Schauder degree is applied to non-symmetric situations.

(iii) *Application scheme of twisted degree*. In this survey article, we will explain how to apply the twisted G-equivariant degree to study various Hopf bifurcation problems (parameterized by $\alpha \in \mathbb{R}$) with a certain symmetry group Γ. To clarify the essence of our approach, we list below the main steps one should follow to attack problem (3).

(a) Let $(\alpha_o, 0)$ be an isolated center for (3) and let $i\beta_o$ be the corresponding purely imaginary characteristic root.

(b) Take a small 'cylinder' $\Omega \subset \mathbb{R} \times \mathbb{R}_+ \times W$ around the point $(\alpha_o, \beta_o, 0)$, construct an *auxiliary G*-invariant function $\varsigma : \overline{\Omega} \to \mathbb{R}$ (see Definition 4.3), confining solutions to (5) to the inside of Ω, i.e. ς is negative on the 'trivial' solutions $(\alpha, \beta, 0)$ and it is positive on the 'exit' set from Ω.

(c) Consider the equation

$$\mathfrak{F}_\varsigma(\alpha, \beta, u) := \big(\varsigma, \mathfrak{F}(\alpha, \beta, u)\big) = 0 \tag{9}$$

(obviously, $\mathfrak{F}_\varsigma$ decreases only one dimension and any solution to (9) is also a solution to (5)).

(d) Define the *local bifurcation invariant* $\omega(\alpha_o, \beta_o)$ containing the topological information about the symmetric nature of the bifurcation, by

$$\omega(\alpha_o, \beta_o) := G\text{-}\mathrm{Deg}^t(\mathfrak{F}_\varsigma, \Omega).$$

(e) Use the equivariant spectral properties of the linearized system at the point $(\alpha_o, \beta_o, 0)$ to extract data needed for the computation of $\omega(\alpha_o, \beta_o)$.

(f) Apply appropriate computer program (for example Maple© routines) in order to obtain *the exact value* of the local invariant $\omega(\alpha_o, \beta_o)$.

(g) Analyze $\omega(\alpha_o, \beta_o)$ in order to obtain the information describing possible branches of non-constant periodic solutions, their multiplicity and symmetric properties.

The fact that the equivariant degree approach to the symmetric Hopf bifurcation allows a computerization (based on the algebraic properties of the twisted degree) of many tedious technicalities related to algebraic nature of this problems (combined with the above mentioned axiomatic approach) constitutes one of the most significant advantages of the twisted degree method. Theoretically, this method supported by computer programming can be applied to any kind of Γ-symmetric Hopf bifurcation problem, with the group Γ being of *arbitrary size*.

(iv) *Historical roots of the twisted degree method.* Twisted equivariant degree is a part of the so-called equivariant degree, which was introduced by Ize et al. in [78] and rigorously studied in [81] for Abelian groups. The idea of the equivariant degree has emanated from different mathematical fields rooted in a variety of concepts and methods. The historical roots of the equivariant degree theory can be traced back to several mathematical fields:

(a) Borsuk–Ulam Theorems (cf. [25,9,24,38,55,81,86,99,121,127,138]; see also references in [99] and [138]);

(b) Fundamental Domains, Equivariant Retract Theory (cf. [9,81,99]; see also [3–7,82, 83,103,107,108]);

(c) Equivariant Obstruction Theory, Equivariant Bordisms, Equivariant Homotopy Groups of Spheres (cf. [37,43,87,105,130,135,139,141]; see also [12,17,18,81,99, 114,131]);

(d) Equivariant General Position Theorems (cf. [22,46,60,81,99]; see also [12,18,91,96, 115,150]);

(f) Generalized Topological Degree, Primary Degree, Topological Invariants of Equivariant Gradient Maps (cf. [39,46,57,59,62,79,81,93,99,126,132–134]);

(g) Geometric Obstruction Theory and J-Homomorphism in Multiparameter Bifurcations (cf. [2,76,77]).

In this article, we will discuss the construction of the twisted equivariant degree without entering into too much details. For more information and proofs, we refer to [19].

Overview

Let us discuss in more detail the contents of this article.

In Subsection 2.1, we include some preliminary results and the equivariant jargon frequently used later. In Subsection 2.2, we give a brief overview of some basic concepts and constructions from representation theory, explain our conventions and collect necessary information needed for the construction and usage of the equivariant degree techniques. In Subsection 2.3, we present some facts related to the notion of G-vector bundles modeled on Banach spaces and describe certain properties of (smooth) G-manifolds. In Subsection 2.4, we discuss the set of unbounded Fredholm operators of index zero $\mathfrak{F}_0(\mathbb{E},\mathbb{F})$ between two Banach spaces $\mathbb{E}$ and $\mathbb{F}$, and describe the topology on this set.

Section 3 naturally splits into four parts: (a) main ideas underlying the notion of twisted degree, (b) construction and basic properties, (c) practical computations, and (d) infinite dimensional extensions.

From the topological point of view, the (twisted) equivariant degree “measures” homotopy obstructions for an equivariant map to have equivariant extensions without zeros on a set composed of several orbit types. Therefore, in Subsection 3.1, we describe the topological ideas related to the construction of the twisted equivariant degree, i.e. the induction over orbit types, concept of fundamental domain and equivariant Kuratowski–Dugundji theorem. Since we follow the “differential viewpoint” to construct the twisted degree, in Subsection 3.2, the notions of normal and regular normal maps (i.e. equivariant replacements of “nice” representatives of homotopy classes) are introduced. In Subsection 3.3, we focus on algebraic properties of the $\mathbb{Z}$-module $A_1^t(G)$ – the range of values of the twisted degree. Namely, we discuss generators of $A_1^t(G)$ (i.e. conjugacy classes of φ-twisted l-folded subgroups of G) and, given two subgroups $L \subset H \subset G$, define purely algebraic quantities $n(L,H)$ allowing us to study an important *multiplication* structure on $A_1^t(G)$. Later on, this multiplication (“module structure”) is used in the same way as the usual multiplication in $\mathbb{Z}$ is used for the multiplicativity property of the Brouwer degree.

In Subsection 3.4, we present a construction of the twisted degree, showing that its coefficients n_i (see (8)) can be evaluated using the usual Brouwer degree of regular normal approximations restricted to fundamental domains. The properties of twisted degree providing an axiomatic approach to its usage, are listed in Subsection 3.5. The particular, nevertheless very important, case of the twisted S^1-degree is discussed in Subsection 3.6. The presented axiomatic definition of the twisted S^1-degree makes no use of the normality condition, therefore it is very close to the axiomatic definition of the Brouwer degree. What is probably more important, this definition opens a way for the practical computation of twisted degree.

To be more specific, in Subsection 3.7, based on the axiomatic definition of S^1-degree, we deduce some computational formulae for S^1-degree of mappings that naturally appear in studying the symmetric Hopf bifurcation phenomenon (cf. Problem 3.32, Theorem 3.39 and Corollary 3.40). In addition, we present the so-called Recurrence Formula (see Theorem 3.41) allowing a direct reduction of computations of the twisted degree to the ones of S^1-degree. Next, in Subsection 3.8, we introduce the concept of *basic maps* and *basic degrees*. These maps are the simplest ones having a non-trivial twisted degree and fitting our approach. Their twisted degrees, which are fully computable (based on the Recurrence Formula and the corresponding S^1-degree results), will constitute a 'library' that can be used by the computer programs in order to evaluate the twisted degree of more complicated maps. Finally, in Subsection 3.9, we establish the multiplicativity property of the twisted degree. This (functorial) property, which is similar to the multiplicativity of the Brouwer degree, plays a substantial role in developing the software needed for practical computations of twisted degree.

In Subsection 3.10, we extend in a standard way the (finite-dimensional) twisted degree to two important classes of equivariant vector fields on Banach G-representations: compact fields and condensing fields. These fields turn out to be enough to cover the applications to the Hopf bifurcation problems we are dealing with in this paper.

In Section 4, we lay down the standard steps of the twisted equivariant degree treatment for an autonomous 1-st order system of ODEs (without symmetries). As it was mentioned above, this system, in spite of having no symmetries, still leads to an S^1-equivariant fixed-point problem. In fact, we use the following strategy: in this section, we consider in detail the *occurrence* of the Hopf bifurcation in ODEs without symmetries (resp. S^1-degree approach) while, in subsequent sections, we analyze (trying to avoid any repetitions) the impact of Γ-symmetries in different classes of dynamical systems to *symmetric properties and minimal number* of bifurcating periodic solutions (resp. $\Gamma \times S^1$-equivariant twisted degree approach). In Subsection 4.1, we give a rigorous definition of the Hopf bifurcation. The corresponding setting in functional spaces is explained in Subsection 4.2. In Subsection 4.3, we introduce the local bifurcation invariant ($=$ S^1-degree of an appropriate map) and establish (in its terms) necessary and sufficient conditions for the occurrence of Hopf bifurcation. To obtain an effective formula for the local bifurcation invariant, we apply (based on the properties of S^1-degree), in Subsection 4.4, appropriate equivariant deformations to simplify the operators in question. In Subsection 4.5, by introducing the concept of the so-called crossing number, we complete the computation of the local bifurcation invariant and formulate the Hopf bifurcation result in terms of the right-hand side of the considered system only.

Section 5 is devoted to a discussion of the Hopf bifurcation problem for a systems of ODEs *with symmetries*. A functional setting for a symmetric Hopf bifurcation and the local bifurcation invariant are described in Subsection 5.1. In particular, for the purpose of estimating *precise* symmetries and a minimal number of bifurcating periodic solutions, we introduce the concept of *dominating orbit types*. The computations of the local invariant based on a reduction to the so-called product formula, are presented in Subsection 5.2 (here we essentially use the multiplicativity property of the twisted degree). The concept of an *isotypical* crossing number and the refinement of the product formula are given in Subsection 5.3. The main steps related to the usage of the twisted equivariant degree method are resumed in Subsection 5.4. In Subsection 5.5, we outline how to use the special Maple© routines, which were developed for the twisted degree computations, to compute the exact value of the local bifurcation invariant. These routines are available on the Internet through the link: http://krawcewicz.net/degree.

Section 6, based on the framework developed in the previous section, is dealing with a general symmetric Hopf bifurcation problem in functional differential equations. Following the standard steps, in Subsection 6.1, we analyze a parametrized system of symmetric delayed functional differential equations. In Subsection 6.2, we briefly discuss particularities related to the usage of the same method in symmetric neutral functional differential equations. Observe that the local bifurcation invariants can be effectively applied to study the problem of continuation of symmetric branches of non-constant periodic solutions (i.e. a global Hopf bifurcation problem) for a system of symmetric functional differential equations (see Subsection 6.3).

In Section 7, we extend the applicability of the twisted degree method to a system of functional parabolic differential equations. A general setting (as an abstract coincidence problem) in functional spaces, appropriate for studying symmetric FPDEs, is presented in Subsection 7.1. In Subsection 7.2, we discuss the Hopf bifurcation problem for a general FPDEs with symmetries. Although, basically the computations of the local bifurcation invariant follow the standard lines, several points specific to this setting are explained in Subsection 7.3.

In Section 8, we illustrate the twisted degree method by applying it to three concrete models. It should be pointed out that our choice of the examples (see the Contents) is motivated by their relative simplicity, practical meaning and the effectiveness of the analysis (via the twisted degree method) of the symmetric Hopf bifurcation phenomenon occurring in these systems. Other examples and more details can be found in [19].

In a short Appendix A, we collect the information about the groups (i.e. dihedral groups D_n and the icosahedral group A_5) and their representations, which are used in our examples presented in Section 8.

2. Auxiliary information

2.1. *Basic definitions and notations*

In this section, G stands for a compact Lie group.

DEFINITION 2.1. A *topological transformation group* is a triple (G, X, φ), where X is a Hausdorff topological space and $\varphi : G \times X \to X$ is a continuous map such that:

(i) $\varphi(g, \varphi(h, x)) = \varphi(gh, x)$ for all g, $h \in G$ and $x \in X$;

(ii) $\varphi(e, x) = x$ for all $x \in X$, where e is the identity element of G.

The map φ is called a *G-action* on X and the space X, together with a given action φ of G, is called a *G-space* (or, more precisely, *left G-action* and *left G-space*, respectively). We shall use the notation $g(x)$, $g \cdot x$ or simply gx, for $\varphi(g, x)$. For $K \subset G$ and $A \subset X$, put $K(A) := \{gx\colon\ g \in K, x \in A\}$ and for $g \in G$ we write $gA := \{gx\colon\ x \in A\}$. A set $A \subset X$

is said to be G-*invariant* if $G(A) = A$. Notice that if A is a compact set, then so is $G(A)$. Observe that on any Hausdorff topological space X one can define the *trivial action* of G by $gx = x$ for all $g \in G$ and $x \in X$.

For any $x \in X$, the closed subgroup $G_x = \{g \in G\colon\ gx = x\}$ of G is called the *isotropy group* of x and the invariant subspace $G(x) := \{gx\colon\ g \in G\}$ of X is called the *orbit* of x. Also, we say that a G-action on X is *free* if $G_x = \{e\}$ for all $x \in X$.

It is easy to see that if H is the isotropy group of $x \in X$, then $G(x)$ is homeomorphic to G/H. Denote by X/G the set of all orbits in X and consider the canonical projection $\pi : X \to X/G$ given by $\pi(x) = G(x)$. The space X/G equipped with the quotient topology induced by π is called the *orbit space* of X under the action of G.

Recall that two closed subgroups H and K of G are said to be *conjugate* in G, if $H = gKg^{-1}$ for some $g \in G$. Clearly, the conjugacy relation is an equivalence relation; denote by (H) the equivalence class of H and call (H) the *conjugacy class* of H in G. Denote by $\mathcal{O}(G)$ the set of all conjugacy classes. The set $\mathcal{O}(G)$ is partially ordered by the relation $\leqslant$ defined as follows:

$$(H) \leqslant (K) \overset{\text{Def}}{\Longleftrightarrow} \exists_{g \in G}\, gHg^{-1} \subset K. \tag{10}$$

Obviously, for a G-space X and $x \in X$, one has $G_{gx} = gG_xg^{-1}$. This gives rise to the notion of the *orbit type* of x defined as the conjugacy class (G_x).

Denote by $\mathcal{J}(X)$ the set of all orbit types occurring in X. Let us point out that according to the order relation (10), if an orbit type (G_x) is smaller than an orbit type (G_y), then the orbit $G(x)$ is “bigger” than the orbit $G(y)$. According to the famous result by Mann (cf. [112]), every action of a compact Lie group on a manifold with finitely generated homology groups has a finite number of orbit types.

The following result is known as Gleason Lemma (cf. [26]).

THEOREM 2.2. *Let X be a metric G-space such that $\mathcal{J}(X) = \{(H)\}$. Then, the orbit map $\pi : X \to X/G$ is a projection in a locally trivial fiber bundle with fiber G/H.*

Suppose that X is a finite-dimensional G-space and G is a compact Lie group. Using the definition of covering dimension (cf. [48]), the Gleason lemma and the Morita theorem (see [120]), which states that $\dim(K \times [0, 1]) = \dim K + 1$ for any metric space K, one can easily prove

PROPOSITION 2.3. *If X is a* (*metric*) *free G-space, then* $\dim(X/G) = \dim X - \dim G$.

For a G-space X and a closed subgroup H of G, we adopt the following notations:

$$\begin{aligned} X_H &:= \{x \in X\colon\ G_x = H\}, \\ X^H &:= \{x \in X\colon\ G_x \supset H\}, \\ X_{(H)} &:= \{x \in X\colon\ (G_x) = (H)\}. \end{aligned}$$

We call X^H the H-*fixed-point subset* of X.

For a closed subgroup H of G, we use $N(H) := \{g\colon\ gHg^{-1} = H\}$ to denote the *normalizer* of H in G and $W(H) := N(H)/H$ to denote the *Weyl group* of H in G. Notice that $N(H)$ is a closed subgroup of G and X^H is $N(H)$-invariant. Consequently, X^H is $W(H)$-invariant, where the $W(H)$-action on X^H is given by $gH \cdot x := gx$ for $g \in N(H)$ and $x \in X^H$. It is also clear that $W(H)$ acts freely on X_H.

Let X and Y be two G-spaces. A continuous map $f : X \to Y$ is called *G-equivariant*, or simply *equivariant*, if

$$\forall g \in G\ \forall x \in X \quad f(gx) = gf(x).$$

If the G-action on Y is trivial, an equivariant map $f : X \to Y$ is called *G-invariant*, or simply *invariant*, i.e.

$$\forall g \in G\ \forall x \in X \quad f(gx) = f(x).$$

Since, for an equivariant map $f : X \to Y$, one has $G_{f(x)} \supset G_x$, it follows that $f(X^H) \subset Y^H$ for every subgroup $H \subset G$. Consequently, the maps $f^H : X^H \to Y^H$ with $f^H := f_{|X^H}$, are well-defined and $W(H)$-equivariant for every subgroup $H \subset G$.

2.2. *Elements of representation theory*

Finite-dimensional G-representations We start with the following

DEFINITION 2.4. Let W be a finite-dimensional real (resp. complex) vector space. We say that W is a real (resp. complex) *representation* of G (in short, *G-representation*), if W is a G-space such that the *translation map* $T_g : W \to W$, defined by $T_g(v) := gv$ for $v \in W$, is an $\mathbb{R}$-linear (resp. $\mathbb{C}$-linear) operator for every $g \in G$.

It is clear that for a G-representation W, the map $T : G \to GL(W)$, given by $T(g) = T_g : W \to W$, is a continuous homomorphism. It is convenient to identify the representation W with the homomorphism $T : G \to GL(W)$. For example, a continuous homomorphism $T : G \to GL(n;\mathbb{R})$ (resp. $T : G \to GL(n;\mathbb{C})$) is called a *real* (resp. *complex*) *matrix G-representation*. For two representations W_1 and W_2, if there is an equivariant isomorphism $A : W_1 \to W_2$, we say that W_1 and W_2 are *equivalent* and write $W_1 \cong W_2$. Let W be a real (resp. complex) G-representation. An inner product (resp. Hermitian inner product) $\langle\cdot,\cdot\rangle : W \oplus W \to \mathbb{R}$ (resp. $\langle\cdot,\cdot\rangle : W \oplus W \to \mathbb{C}$) is called *$G$-invariant* if $\langle gu, gv\rangle = \langle u, v\rangle$ for all $g \in G$, u, $v \in W$. A G-representation together with a G-invariant inner product is called an *orthogonal* (resp. *unitary*) *G-representation*. It is well-known that every real (resp. complex) G-representation is equivalent to an orthogonal (resp. unitary) representation $T : G \to O(n)$ (resp. $T : G \to U(n)$).

Notice that any G-representation W is a manifold with trivial homology groups in non-zero dimensions, therefore (cf. [112]), there are only finitely many orbit types in W.

An invariant linear subspace $\widetilde{W} \subset W$ is called a *subrepresentation* of W and we say that W is an *irreducible* representation if it has no subrepresentation different from $\{0\}$ and W. Otherwise, W is called *reducible*.

The *complete reducibility theorem* states that every (finite-dimensional) G-representation W is a (not necessarily unique) direct sum of irreducible subrepresentations of W, i.e. there exist irreducible subrepresentations $\mathcal{W}^1, \dots, \mathcal{W}^m$ of V such that

$$W = \mathcal{W}^1 \oplus \mathcal{W}^2 \oplus \cdots \oplus \mathcal{W}^m.$$

Let W_1 and W_2 be two G-representations. Denote by $L^G(W_1, W_2)$ the space of all linear G-equivariant maps $A : W_1 \to W_2$, and by $GL^G(W_1, W_2)$ its subspace of all (G-equivariant) isomorphisms. Also, put $L^G(W) := L^G(W, W)$ and $GL^G(W) := GL^G(W, W)$.

Let $\mathcal{W}^1$ and $\mathcal{W}^2$ be two real or complex irreducible G-representations. Then, the Schur lemma states that every equivariant linear map $A : \mathcal{W}^1 \to \mathcal{W}^2$ is either an isomorphism or zero. Assume $\mathcal{U}$ is a *complex* irreducible G-representation. Then, it follows from Schur Lemma that every equivariant linear map $A : \mathcal{U} \to \mathcal{U}$ satisfies $A = \lambda\,\mathrm{Id}$, for some $\lambda \in \mathbb{C}$, i.e. the G-representation $\mathcal{U}$ is *absolutely irreducible* (cf. [27]). Consequently, we have that $\dim_{\mathbb{C}} L^G(\mathcal{U}^1, \mathcal{U}^2) = 1$ or 0 (where $\mathcal{U}^1$ and $\mathcal{U}^2$ are two irreducible complex G-representations). Using this fact, it can be easily proved that every complex irreducible G-representation of an Abelian compact Lie group G is one-dimensional.

In the case $\mathcal{V}$ is a *real* irreducible G-representation, the set $L^G(\mathcal{V})$ is a finite-dimensional associative division algebra over $\mathbb{R}$, so it is either $\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$, and we call $\mathcal{V}$ to be of *real*, *complex* or *quaternionic type*, respectively. Observe also that the type of a real irreducible G-representation is closely related to its *complexification* (cf. [27]).

REMARK 2.5 (Convention of notation). Let us explain our convention, which we use in connection to the complex and real G-representations. As long as it is possible, we use the letter V to denote a real G-representation, while the letter U is reserved for complex G-representations. In the case the type of a G-representation is not specified, we apply the letter W. Since, for a given compact Lie group G, there are only countably many irreducible G-representations (see [85,151]), we also assume that a complete list, indexed by numbers $0, 1, 2, 3, \dots$, of these irreducible representation is available, and, in the case of real G-representations, we denote them by $\mathcal{V}_0, \mathcal{V}_1, \mathcal{V}_2, \dots$ (where $\mathcal{V}_0$ always stands for the trivial irreducible G-representation), in the case of complex G-representations, by $\mathcal{U}_0, \mathcal{U}_1, \mathcal{U}_2, \dots$ (where $\mathcal{U}_0$ is the trivial complex irreducible G-representation), and in the case the type of an irreducible G-representation is not clearly specified as real or complex, we denote them by $\mathcal{W}_0, \mathcal{W}_1, \mathcal{W}_2, \dots$ (where again $\mathcal{W}_0$ is the trivial irreducible G-representation). Unspecified irreducible G-representations are denoted as follows: in the case of real representations $\mathcal{V}$, $\mathcal{V}^1$, or $\mathcal{V}^k$, in the case of complex representations $\mathcal{U}$, $\mathcal{U}^1$, or $\mathcal{U}^k$, and if the type is unknown $\mathcal{W}$, $\mathcal{W}^1$, or $\mathcal{W}^k$. We summarize our convention in Table 1.

REMARK AND NOTATION 2.6. Let Γ be a compact Lie group.

(i) Any (irreducible) complex Γ-representation can be converted in a natural way to an (irreducible) real $\Gamma \times S^1$-representation as follows. For any complex Γ-representation U and $l = 1, 2, \dots$, define a $\Gamma \times S^1$-action on U by

$$(\gamma, z)w = z^l \cdot (\gamma w), \quad (\gamma, z) \in \Gamma \times S^1,\ w \in U, \tag{11}$$

Table 1
Notational convention for real and complex G-representations

	Real	Complex	Unspecified
G-representation	$V, \mathfrak{V}$	$U, \mathfrak{U}$	$W, \mathfrak{W}$
Irreducible G-representation	$\mathcal{V}$	$\mathcal{U}$	$\mathcal{W}$
List of all irreducible G-representations	$\mathcal{V}_0, \mathcal{V}_1, \mathcal{V}_2, \dots$	$\mathcal{U}_0, \mathcal{U}_1, \mathcal{U}_2, \dots$	$\mathcal{W}_0, \mathcal{W}_1, \mathcal{W}_2, \dots$
Various irreducible G-representations	$\mathcal{V}, \mathcal{V}^1, \mathcal{V}^2, \mathcal{V}^j$	$\mathcal{U}, \mathcal{U}^1, \mathcal{U}^2, \mathcal{U}^j$	$\mathcal{W}, \mathcal{W}^1, \mathcal{W}^2, \mathcal{W}^j$

where '$\cdot$' is the complex multiplication. This real $\Gamma \times S^1$-representation is denoted by ${}^l U$. Moreover, if U is a complex irreducible Γ-representation, then ${}^l U$ is a real irreducible $\Gamma \times S^1$-representation.

(ii) Following Remark 2.5, assume that $\{\mathcal{U}_j\}$ is a *complete* list of irreducible complex Γ-representations. The (real) irreducible $\Gamma \times S^1$-representation ${}^l\mathcal{U}_j$ is called the l-th irreducible $\Gamma \times S^1$-representation *associated* with $\mathcal{U}_j$ and denoted by $\mathcal{V}_{j,l}$.

Complexification and conjugation For a real vector space V, denote by V^c the *complexification* of V given by

$$V^c := \mathbb{C} \otimes_{\mathbb{R}} V.$$

Assume further that V is a real G-representation. Then, V^c has a natural structure of a complex G-representation defined by $g(z \otimes v) = z \otimes gv$, $z \in \mathbb{C}$, $v \in V$.

For a complex vector space U, denote by $\overline{U}$ the conjugate complex vector space structure on U, i.e. the space U with the complex multiplication given by $z \cdot v := \bar{z}v$, $z \in \mathbb{C}$, $v \in U$. Notice that $GL(U) = GL(\overline{U})$, therefore, if U is a complex G-representation, then so is $\overline{U}$, which is called the G-representation *conjugate* to U. In the case of a complex matrix G-representation $T : G \to GL(n, \mathbb{C})$, the G-representation conjugate to T is given by $\overline{T} : G \to GL(n, \mathbb{C})$, where $\overline{T}(g)$ denotes the matrix obtained from $T(g)$ by replacing its entries with their conjugates.

REMARK 2.7. For a (real) vector space V, an element x of its complexification V^c can be written in a unique way as $x = 1 \otimes u + \mathrm{i} \otimes v$, where $u, v \in V$. Using this representation of elements in V^c, it is easy to show that if V has a complex structure (i.e. an isomorphism $J : V \to V$ satisfying $J^2 = -\mathrm{Id}$), then the space V^c is isomorphic (as a complex vector space) to the direct sum $V \oplus \overline{V}$, where $\overline{V}$ stands for the (complex) vector space *conjugate* to V, i.e. the space V with the complex multiplication given by $z \cdot v := \bar{z}v$. Indeed, notice that for every $x \in V^c$,

$$\begin{aligned} x &= 1 \otimes u + \mathrm{i} \otimes v \\ &= 1 \otimes \frac{u + \mathrm{i}v}{2} + \mathrm{i} \otimes \frac{v - \mathrm{i}u}{2} + 1 \otimes \frac{u - \mathrm{i}v}{2} + \mathrm{i} \otimes \frac{v + \mathrm{i}u}{2}, \end{aligned}$$

so we obtain the following direct decomposition $V^c = V_1 \oplus V_2$, where

$$V_1 = \left\{ 1 \otimes \frac{u + \mathrm{i}v}{2} + \mathrm{i} \otimes \frac{v - \mathrm{i}u}{2} \colon u, v \in V \right\},$$

$$V_2 = \left\{ 1 \otimes \frac{u - \mathrm{i}v}{2} + \mathrm{i} \otimes \frac{v + \mathrm{i}u}{2} \colon u, v \in V \right\}.$$

It is easy to verify that V_1 is $\mathbb{C}$-isomorphic to V and V_2 to $\overline{V}$.

REMARK 2.8. It is well-known (see [27]) that for a real irreducible G-representation V, the complex G-representation V^c is irreducible if and only if V is of real type. Otherwise, it follows from Remark 2.7 that if V has a natural complex structure, then V^c, as a complex G-representation, is equivalent to $V \oplus \overline{V}$. In this case V is equivalent (as a complex G-representation) to $\overline{V}$, if and only if V is of quaternionic type.

Character of representation For a finite-dimensional real (resp. complex) G-representation W, with the corresponding homomorphism $T : G \to GL(W)$, the function $\chi_W : G \to \mathbb{R}$ (resp. $\chi_W : G \to \mathbb{C}$), defined by

$$\chi_W(g) = \mathrm{Tr}\big(T(g)\big), \quad g \in G,$$

where Tr stands for the trace, is called the *character* of W. It is well-known (see, for example, [27]) that $\chi_W(ghg^{-1}) = \chi_W(h)$, for $g, h \in G$, and for two G-representations (both being either real or complex) W_1 and W_2, we have $\chi_{W_1 \oplus W_2} = \chi_{W_1} + \chi_{W_2}$. Let us point out that any G-representation is completely determined by its character.

Haar integral Recall the notion of the *Haar integral* on G, denoted by $\int_G f(g)\,\mathrm{d}\mu(g)$, where $f : G \to \mathbb{R}$ is a continuous function. There exists a unique functional $f \to \int_G f(g)\,\mathrm{d}\mu(g)$, on the space of continuous functions on G, satisfying the following properties:

(i) $\int_G (f_1(g) + f_2(g))\,\mathrm{d}\mu(g) = \int_G f_1(g)\,\mathrm{d}\mu(g) + \int_G f_2(g)\,\mathrm{d}\mu(g)$;

(ii) $\int_G cf(g)\,\mathrm{d}\mu(g) = c\int_G f(g)\,\mathrm{d}\mu(g)$, where $c \in \mathbb{R}$;

(iii) $\int_G \mathrm{d}\mu(g) = 1$;

(iv) $\int_G f(h^{-1}g)\,\mathrm{d}\mu(g) = \int_G f(gh)\,\mathrm{d}\mu(g) = \int_G f(g^{-1})\,\mathrm{d}\mu(g) = \int_G f(g)\,\mathrm{d}\mu(g)$, for all $h \in G$;

(v) $\int_G f(g)\,\mathrm{d}\mu(g) \geqslant 0$ for $f(g) \geqslant 0$, $\forall g \in G$.

Isotypical decomposition Consider a real G-representation V. The representation V can be decomposed into a direct sum

$$V = \mathcal{V}^1 \oplus \mathcal{V}^2 \oplus \cdots \oplus \mathcal{V}^m \tag{12}$$

of irreducible subrepresentations $\mathcal{V}^i$ of V, some of them may be equivalent. This direct decomposition is not "geometrically" unique and is only defined up to isomorphism. Of course, among these irreducible subrepresentations there may be distinct (non-equivalent) subrepresentations which we denote by $\mathcal{V}_{k_1}, \dots, \mathcal{V}_{k_r}$, including possibly the trivial one-dimensional representation $\mathcal{V}_0$. Let V_{k_i} be the sum of all irreducible subspaces $\mathcal{V}^o \subset V$ equivalent to $\mathcal{V}_{k_i}$. Then,

$$V = V_{k_1} \oplus V_{k_2} \oplus \cdots \oplus V_{k_n} \tag{13}$$

and the direct sum (13) is called the *isotypical decomposition* of V. In contrast to the decomposition (12), the isotypical decomposition (13) is unique. The subspaces V_{k_i} are called the *isotypical* components of V (of type $\mathcal{V}_{k_i}$ or modeled on $\mathcal{V}_{k_i}$). It is also convenient to write the isotypical decomposition (13) in the form

$$V = V_0 \oplus V_1 \oplus \cdots \oplus V_r, \quad \text{for some } r \geqslant 0, \tag{14}$$

where the isotypical components V_i are modeled on $\mathcal{V}_i$, according to the complete list of irreducible G-representations (some V_i may be trivial subspaces).

The isotypical components V_i, $i = 0, 1, 2, \dots, r$, can be also described in another way, which is more useful for infinite dimensional generalizations. Denote by $\chi_i : G \to \mathbb{R}$ the real character of the irreducible representation $\mathcal{V}_i$, $i = 0, 1, 2, \dots, r$. Define the linear map $P_i : V \to V$ by

$$P_i x = n(\mathcal{V}_i) \int_G \chi_i(g) g x \, \mathrm{d}\mu(g), \quad x \in V, \tag{15}$$

where

$$n(\mathcal{V}_i) = \begin{cases} \dim_{\mathbb{R}} \mathcal{V}_i, & \text{if } \mathcal{V}_i \text{ is of real type,} \\ \dfrac{\dim_{\mathbb{R}} \mathcal{V}_i}{2}, & \text{if } \mathcal{V}_i \text{ is of complex type,} \\ \dfrac{\dim_{\mathbb{R}} \mathcal{V}_i}{4}, & \text{if } \mathcal{V}_i \text{ is of quaternionic type.} \end{cases}$$

The number $n(\mathcal{V}_i)$ defined above, is called the *intristic dimension* of $\mathcal{V}_i$. Then (see [93] for more details):

(a) $x \in V_i \Longleftrightarrow P_i(x) = x$;
(b) $x \in V_l, l \neq i \Longrightarrow P_i(x) = 0$;
(c) $P_i \circ P_i(x) = P_i(x)$ for all $x \in V$;
(d) $P_i : V \to V$ is G-equivariant.

Consequently, every $x \in V$ can be written as

$$x = \sum_{i=0}^{r} P_i(x),$$

where $P_i(x) \in V_i$, so $\mathrm{Id} = \sum_{i=0}^{r} P_i$.

In the case U is a complex G-representation, a similar *complex isotypical decomposition* of U can be constructed, i.e.

$$U = U_0 \oplus U_1 \oplus \cdots \oplus U_s, \quad \text{for some } s \geqslant 0,$$

where the isotypical component U_j is modeled on the complex irreducible G-representation $\mathcal{U}_j$, $j = 0, 1, \dots, s$.

Decomposition of $GL^G(V)$ Let V be an orthogonal G-representation. We have the following standard algebraic facts on a decomposition of $GL^G(V)$.

PROPOSITION 2.9. (Cf. [85].) *Let (cf.* (13))

$$V = V_{k_1} \oplus \cdots \oplus V_{k_r}, \tag{16}$$

be the G-isotypical decomposition, where a component V_{k_i} is modeled on an irreducible representation $\mathcal{V}_{k_i}$. Then:

(i) $GL^G(V) = \bigoplus_{i=1}^{r} GL^G(V_{k_i})$;

(ii) *for any isotypical component V_{k_i} from* (16), *we have $GL^G(V_{k_i}) \simeq GL(m, \mathbb{F})$, where $m = \dim V_{k_i} / \dim \mathcal{V}_{k_i}$ and $\mathbb{F} \simeq GL^G(\mathcal{V}_{k_i})$, i.e. $\mathbb{F} = \mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$, depending on the type of the irreducible representation $\mathcal{V}_{k_i}$.*

Banach G-representations Recall

DEFINITION 2.10. Let W be a real (resp. complex) Banach space. We say that W is a real (resp. complex) *Banach representation* of G (in short *Banach G-representation*) if the space W is a G-space such that the translation map $T_g : W \to W$, defined by $T_g(w) = gw$ for $w \in W$, is a *bounded* $\mathbb{R}$-linear (resp. $\mathbb{C}$-linear) operator for every $g \in G$.

Clearly, every finite-dimensional G-representation is a Banach G-representation.

We say that a Banach G-representation W is *isometric* if for each $g \in G$, the translation operator $T_g : W \to W$ is an isometry, i.e. $\|T\|_g w = \|w\|$ for all $w \in W$, and we call the norm $\|\cdot\|$ a *G-invariant* norm. Using the Haar integral, it can be proved that for every Banach G-representation W, it is possible to construct a new G-invariant norm on W equivalent to the initial one.

A closed G-invariant linear subspace of W is called a Banach subrepresentation. It is also important to notice that all irreducible Banach G-representations (i.e. representations that do not contain any proper non-trivial Banach G-subrepresentations) are finite-dimensional (see [85] or [93]). Notice that for a closed subgroup $H \subset G$, the set W^H is a closed linear subspace of W.

In the case W is a real (resp. complex) Hilbert space, the inner (resp. Hermitian inner) product $\langle \cdot, \cdot \rangle$ on W is called *G-invariant* if $\langle gv, gw \rangle = \langle v, w \rangle$ for all $g \in G$, $v, w \in W$. In this case, W is called an *isometric Hilbert* (resp. *unitary Hilbert*) *G-representation*.

Consider the complete list $\{\mathcal{V}_k\colon\ k = 0, 1, 2, \dots\}$ of all irreducible G-representations (which is a countable set [27]) and let $\chi_k : G \to \mathbb{R}$ be the corresponding character of

$\mathcal{V}_k$ for $k = 0, 1, 2, \ldots$. Take a real Banach G-representation and define the linear maps $P_k : W \to W$ by

$$P_k x = n(\mathcal{V}_k) \int_G \chi_k(g) g x \, \mathrm{d}\mu(g), \quad g \in G, \ x \in W, \ k = 0, 1, 2, \ldots, \tag{17}$$

where $n(\mathcal{V}_k)$ denotes the intristic dimension of $\mathcal{V}_k$.

Then, similarly to the finite-dimensional case, we have that $P_k : W \to W$ is a *G-equivariant* (i.e. $P_k(gw) = g P_k(w)$ for $g \in G$ and $w \in W$) bounded linear projection onto the subspace

$$W_k := P_k(W). \tag{18}$$

Also (see [93]), we have the following

THEOREM 2.11. *Let W be a real isometric Banach representation of a compact Lie group G, $\mathcal{V}$ a real irreducible representation of G and χ the character of $\mathcal{V}$. Then, the linear operator $P_{\mathcal{V}} : W \to W$ defined by*

$$P_{\mathcal{V}} x = n(\mathcal{V}) \int_G \chi(g) g x \, \mathrm{d}\mu(g), \quad x \in W,$$

is a bounded G-equivariant projection on the subspace $P_{\mathcal{V}}(W)$ satisfying the following properties:

(i) *If $x \in W$ belongs to a representation space of an irreducible subrepresentation of W that is equivalent to $\mathcal{V}$, then $P_{\mathcal{V}} x = x$;*

(ii) *If $x \in W$ belongs to a representation space of an irreducible subrepresentation of W that is not equivalent to $\mathcal{V}$, then $P_{\mathcal{V}} x = 0$.*

It is an immediate consequence of Theorem 2.11 that every irreducible subrepresentation of W, which is equivalent to $\mathcal{V}_k$, is contained in W_k. The G-invariant subspace W_k is called the *isotypical component* of W corresponding to $\mathcal{V}_k$. Define the subspace

$$W_\infty := \bigoplus_k W_k \tag{19}$$

which is clearly dense in W, i.e. we have $\overline{W_\infty} = W$. Consequently, the decomposition

$$W = \overline{\bigoplus_k W_k} \tag{20}$$

is called the *isotypical decomposition* of W. Moreover, for every G-equivariant linear operator $A : W \to W$, we have that $A(W_k) \subseteq W_k$ for all $k = 0, 1, 2, \ldots$.

Using the Zorn lemma one can easily establish

PROPOSITION 2.12. *Given* (19) *and* (20), *for any finite subset $X \subset W_\infty$, the subspace* $\operatorname{span} G(X)$ *spanned by the orbits of points from X, is finite-dimensional and G-invariant.*

2.3. *G-vector bundles and G-manifolds*

Let E and B be two topological spaces, V a Banach space, and $p\colon E \to B$ a continuous map which satisfies the following conditions:

(1) For each $x \in B$, the set $p^{-1}(x)$ has a structure of a real Banach space (with topology induced from E);

(2) For each $x \in B$, there exists an open neighborhood U and a homeomorphism $\varphi_U : p^{-1}(U) \to U \times V$ such that the following diagram commutes

$$\begin{tikzcd}
p^{-1}(U) \arrow[rr, "\varphi_U"] \arrow[dr, "p"'] & & U \times V \arrow[dl, "\pi_1"', "\pi_1(u,v)=u"] \\
& U &
\end{tikzcd}$$

and, in addition,

(3) For each $x \in U$ the map $\varphi_{U,x} := (\varphi_U)_{|p^{-1}(x)} \colon p^{-1}(x) \to \{x\} \times V =: V$ is an isomorphism of Banach spaces.

Then, the triple $\xi = (p, E, B)$ is called a *Banach vector bundle* modeled on the Banach space V, E – *total space*, B – *base space*, $p^{-1}(x)$ – *fiber over* x, p – *vector bundle projection* and the pair (U, φ_U) – *local trivialization*.

A Banach vector bundle $\xi = (p, E, B)$, where E, B are two G-spaces, is called a *G-vector bundle* if

(a) p is an equivariant map;

(b) For every $g \in G$, the map $g\colon p^{-1}(x) \to p^{-1}(gx)$, defined by $g(v) = gv$, $v \in p^{-1}(x)$, is an isomorphism of Banach spaces.

A G-morphism of two G-vector bundles $\xi = (p, E, B)$ and $\xi' = (p', E', B')$ is a pair of G-equivariant maps (φ, ψ), $\varphi\colon E \to E'$ and $\psi : B \to B'$, such that the following diagram commutes

$$\begin{tikzcd}
E \arrow[r, "\varphi"] \arrow[d, "p"] & E' \arrow[d, "p'"'] \\
B \arrow[r, "\psi"] & B'
\end{tikzcd}$$

and $\varphi_x := \varphi_{|p^{-1}(x)} \colon p^{-1}(x) \to p'^{-1}(\psi(x))$ is a linear (bounded) operator. If φ and ψ are two G-equivariant homeomorphisms, we say that the G-vector bundles (p, E, B) and (p', E', B') are G-isomorphic.

If M is a G-space with a structure of a finite-dimensional smooth manifold such that the action $\varphi\colon G \times M \to M$ of G on M is a smooth map, then M is called a *G-manifold*. Given an (orthogonal) G-representation V, any open invariant subset (equipped with the action induced from V) provides an example of a G-manifold.

In the case of a G-vector bundle (p, E, B) such that E and B are G-manifolds and $p: E \to B$ is a smooth mapping admitting smooth local trivializations, we say that (p, E, B) is a *smooth G-vector bundle*. If M is a G-manifold, then it is easy to see that the *tangent vector bundle* $\tau(M)$ of M is a smooth G-vector bundle. Let M be a Riemannian G-manifold. By using the Haar integral, it is easy to construct a G-invariant Riemannian metric $\langle\cdot,\cdot\rangle : \tau(M) \times \tau(M) \to \mathbb{R}$. Suppose that M is a G-submanifold of a Riemannian G-manifold W (equipped with an invariant metric). Then, the *normal vector bundle* $\nu(M)$ of M in W is a smooth G-vector bundle (in what follows, we will use the symbol $\nu_x(M)$ to denote the normal slice at $x \in M$).

Using the standard G-vector bundle techniques one can easily establish

PROPOSITION 2.13. *Assume that N is a G-submanifold of a Riemannian G-manifold M. Then, for every G-invariant compact set $K \subset N$, there exists an invariant neighborhood U of K, called invariant tubular neighborhood of N over K, satisfying the properties*:

(a) *$U_o := U \cap N$ is an invariant neighborhood of K in N;*

(b) *there exists $\varepsilon > 0$ such that the exponential map $\exp : \nu(N, \varepsilon)_{|U_o} \to M$ is a G-diffeomorphism onto U, where $\nu(N, \varepsilon)_{|U_o}$ denotes the ε-disc bundle of the normal bundle $\nu(N)$ restricted to U_o. In particular, every point $x \in U$ can be represented by a pair $(u, v) \in \nu(N, \varepsilon)_{|U_o}$, where $u \in U_o$ and v is a vector of norm less than ε orthogonal to N at u.*

Notice that if $M = V$, where V is an orthogonal G-representation, the map $\exp : \nu(N, \varepsilon)_{|U_o} \to V$ is simply defined by $\exp(u, v) = u + v$.

We complete this subsection with the following important

THEOREM 2.14. (Cf. [84,26].) *Let M be a G-manifold and H a subgroup of G. Then*:

(i) *$M_{(H)}$ is a G-invariant submanifold of M;*

(ii) *$M_{(H)}/G$ is a manifold. If $M_{(H)}$ is connected, then $M_{(H)}/G$ is also connected;*

(iii) *If (H) is a maximal orbit type in M, then $M_{(H)}$ is closed in M;*

(iv) *If (H) is a minimal orbit type in M and M/G is connected, then $M_{(H)}/G$ is a connected, open and dense subset of M/G;*

(v) *M_H is a $W(H)$-manifold with free $W(H)$-action, and $M_H/W(H)$ is a smooth manifold,*

where the minimal and maximal orbit types are taken with respect to the partial order relation (10).

2.4. *Fredholm operators*

Let $\mathbb{E}$ and $\mathbb{F}$ be two Banach spaces. Consider on $\mathbb{E} \oplus \mathbb{F}$ the norm defined by $\|x\| + \|y\|$ for $x \in \mathbb{E}$ and $y \in \mathbb{F}$. An (unbounded in general) linear operator $L : \mathrm{Dom}(L) \to \mathbb{F}$ (where $\mathrm{Dom}(L) \subset \mathbb{E}$ is a dense subspace), is called a *Fredholm operator* if

(i) L is a *closed* operator, i.e. the graph $\mathrm{Gr}(L)$ of L given by

$$\mathrm{Gr}(L) := \bigl\{(v, Lv)\colon\ v \in \mathrm{Dom}(L)\bigr\},$$

is a closed subspace in $\mathbb{E} \oplus \mathbb{F}$,

(ii) $\mathrm{Im}(L) := \{Lv\colon\ v \in \mathrm{Dom}(L)\}$ is a closed subspace of $\mathbb{F}$,

(iii) $\dim\ker L$ and $\operatorname{codim}\operatorname{Im} L := \dim \mathbb{F}/\operatorname{Im} L$ are finite.

For a given Fredholm operator L, the number $i(L) = \dim\ker L - \dim \mathbb{F}/\operatorname{Im}(L)$ is called the *index* of L.

Let $L\colon \mathrm{Dom}(L) \subset \mathbb{E} \to \mathbb{F}$ be an unbounded Fredholm operator and denote by $\pi_1\colon \mathbb{E} \oplus \mathbb{F} \to \mathbb{E}$ (resp. $\pi_2\colon \mathbb{E} \oplus \mathbb{F} \to \mathbb{F}$) the natural projection on $\mathbb{E}$ (resp. $\mathbb{F}$). Since $\pi_1\colon \mathrm{Gr}(L) \to \mathrm{Dom}(L)$ is a bounded linear operator, which is one-to-one and onto, the subspace $\mathrm{Dom}(L)$ can be equipped with a new norm $\|\cdot\|_L$ defined by

$$\|v\|_L := \|v\|_{\mathbb{E}} + \|Lv\|_{\mathbb{F}}, \tag{21}$$

where $\|\cdot\|_{\mathbb{E}}$ (resp. $\|\cdot\|_{\mathbb{F}}$) denotes the norm in $\mathbb{E}$ (resp. in $\mathbb{F}$), i.e. the norm $\|v\|_L$ is simply the norm of $\pi_1^{-1}(v)$ in $\mathbb{E} \oplus \mathbb{F}$. Since π_1 is one-to-one, we immediately obtain that $\mathbb{E}_L := (\mathrm{Dom}(L), \|\cdot\|_L)$ is a Banach space (equipped with so-called "*graph norm*") and the operator $L\colon \mathbb{E}_L \to \mathbb{F}$ is a bounded operator. Since $\ker L$ and $\operatorname{Im} L$ are still the same, the operator $L\colon \mathbb{E}_L \to \mathbb{F}$ is a bounded Fredholm operator of the same index as the original unbounded operator $L\colon \mathrm{Dom}(L) \subset \mathbb{E} \to \mathbb{F}$.

Consider the set $\mathrm{Sub}(\mathbb{E} \oplus \mathbb{F})$ of all the closed subspaces in $\mathbb{E} \oplus \mathbb{F}$ and denote by $\mathrm{Op}(\mathbb{E}, \mathbb{F})$ the set of all (in general unbounded) densely defined closed linear operators $L\colon \mathrm{Dom}(L) \subset \mathbb{E} \to \mathbb{F}$. It is convenient to identify any such operator L with its graph $\mathrm{Gr}(L)$, thus $\mathrm{Op}(\mathbb{E}, \mathbb{F})$ can be considered as a subspace of $\mathrm{Sub}(\mathbb{E} \oplus \mathbb{F})$.

The set $\mathrm{Sub}(\mathbb{E} \oplus \mathbb{F})$ and consequently, $\mathrm{Op}(\mathbb{E}, \mathbb{F})$ can be equipped with the *Hausdorff metric*. More precisely, consider a Banach space $\mathbb{V}$ and the set $\mathfrak{B}(\mathbb{V})$ consisting of all bounded closed subsets of $\mathbb{V}$. Then, for two sets $X, Y \in \mathfrak{B}(\mathbb{V})$, define

$$D(X, Y) := \inf\bigl\{r > 0\colon\ Y \subset X + B_r(0)\bigr\}, \quad B_r(0) = \bigl\{v \in \mathbb{V}\colon\ \|v\|_{\mathbb{V}} < r\bigr\}.$$

The *Hausdorff metric* d_H on $\mathfrak{B}(\mathbb{V})$ is given by

$$d_H(X, Y) := \max\bigl\{D(X, Y), D(Y, X)\bigr\}, \quad X, Y \in \mathfrak{B}(\mathbb{V}). \tag{22}$$

Using the Hausdorff metric, define the metric on $\mathrm{Sub}(\mathbb{E} \oplus \mathbb{F})$ by

$$d(V, W) := d_H\bigl(S(V), S(W)\bigr), \quad V, W \in \mathrm{Sub}(\mathbb{E} \oplus \mathbb{F}), \tag{23}$$

where $S(V)$ (resp. $S(W)$) denotes the unit sphere in V (resp. in W).

THEOREM 2.15. *The set* $\mathfrak{F}_0(\mathbb{E}, \mathbb{F})$ (*of Fredholm operators of index zero*) *is open in* $\mathrm{Op}(\mathbb{E}, \mathbb{F})$.

Theorem 2.15 (belonging to a functional analysis folklore) provides a theoretical basis for many of the arguments justifying the functional settings used in what follows. In particular,

COROLLARY 2.16.

(a) *Let* $L \in \mathfrak{F}_0(\mathbb{E}, \mathbb{E})$ *and assume that* $0 \in \sigma(L)$, *where* $\sigma(L)$ *denotes the spectrum of* L. *Then, for all sufficiently small reals* $t > 0$, $L - t\,\mathrm{Id}$ *is a one-to-one* (*bijective onto* $\mathbb{E}$) *Fredholm operator of index zero* (*in particular,* 0 *is an eigenvalue of* L *of finite multiplicity and it is an isolated point in* $\sigma(L)$).

(b) *Let* $L \in \mathfrak{F}_0(\mathbb{E}, \mathbb{E})$ *and let* $j : \mathbb{E}_L \to \mathbb{E}$ *be a compact operator. Then, for all* $t \in \mathbb{R}$, $L - t\,\mathrm{Id} \in \mathfrak{F}_0(\mathbb{E}, \mathbb{E})$ (*in particular,* $\sigma(L)$ *is a discrete in* $\mathbb{R}$ *set composed of eigenvalues of* L, *all of them of finite multiplicity*).

Observe that Theorem 2.15 admits an equivariant version. Namely, let $\mathbb{E}$ and $\mathbb{F}$ be real isometric Banach G-representations. Denote by $\mathrm{Op}^G := \mathrm{Op}^G(\mathbb{E} \oplus \mathbb{F})$ the set of all closed G-equivariant linear operators from $\mathbb{E}$ to $\mathbb{F}$. Clearly, for $L \in \mathrm{Op}^G$, the graph $\mathrm{Gr}(L)$ is a closed invariant subspace of $\mathbb{E} \oplus \mathbb{F}$, where we assume that G acts diagonally on $\mathbb{E} \oplus \mathbb{F}$.

The space $\mathbb{E}_L$ (cf. (21)) is a Banach G-representation. It is clear that $L : \mathbb{E}_L \to \mathbb{F}$ is a continuous equivariant operator.

Equip Op^G with the metric

$$\mathrm{dist}(L_1, L_2) = d\big(\mathrm{Gr}(L_1), \mathrm{Gr}(L_2)\big), \quad L_1, L_2 \in \mathrm{Op}^G,$$

where $d(\cdot,\cdot)$ is the metric on $\mathrm{Sub}(\mathbb{E} \oplus \mathbb{F})$ defined by (23). Let $\mathfrak{F}_0^G$ be the set of all closed G-equivariant Fredholm operators of index zero from $\mathbb{E}$ to $\mathbb{F}$. Since $\mathfrak{F}_0^G = \mathfrak{F}_0 \cap \mathrm{Op}^G$, by Theorem 2.15, $\mathfrak{F}_0^G$ is an open subset of Op^G.

We complete this subsection with the following important

REMARK AND NOTATION 2.17. Consider a Fredholm operator of index zero $L : \mathrm{Dom}(L) \subset \mathbb{E} \to \mathbb{F}$. A finite-dimensional linear operator $K : \mathbb{E} \to \mathbb{F}$ is called a (finite-dimensional) *resolvent* of L if the map $L + K : \mathrm{Dom}(L) \to \mathbb{F}$ is one-to-one. Since the operator $L : \mathbb{E}_L \to \mathbb{F}$ is continuous, $L + K : \mathbb{E}_L \to \mathbb{F}$ is also continuous and one-to-one. Hence, using open mapping theorem and the fact that a compact linear perturbation of a (bounded) Fredholm operator does not change its index, we obtain that $L + K$ is surjective and $(L + K)^{-1} : \mathbb{F} \to \mathbb{E}_L$ is bounded. Consequently, by applying the natural inclusion $j : \mathbb{E}_L \hookrightarrow \mathbb{E}$, the inverse $(L + K)^{-1} : \mathbb{F} \to \mathbb{E}$ is a bounded operator. Moreover, if the natural inclusion j is compact, the inverse $(L + K)^{-1}$ is also compact.

2.5. *Bibliographical remarks*

There is a lot of excellent graduate texts and monographs devoted to Lie group theory (see, for instance, [144,29,143,44]). For the background on transformation groups and G-spaces we refer to [26,84,43]. The material related to compact Lie group representations (both finite- and infinite dimensional) can be found in [23,27,58,142,151,152].

For the concepts and constructions related to smooth equivariant topology we refer to [26,37,84] (see also [54,72] for the fiber bundle background). The proof of Theorem 2.15 can be found, for instance, in [19].

3. Twisted equivariant degree: Construction and basic properties

3.1. *Topology behind the construction: Equivariant extensions and fundamental domains*

Induction over Orbit Types As it was mentioned in the Introduction, the equivariant degree "measures" homotopy obstructions for an equivariant map to have equivariant extensions without zeros on a set composed of several orbit types. Therefore, in this subsection we briefly discuss the following problem:

$$(P_A)\quad \begin{cases} \textit{Assume that } V \textit{ is a finite-dimensional } G\textit{-representation, } Y := V \setminus \{0\}, \\ X \textit{ is a } G\textit{-space and } A \subset X \textit{ is a closed invariant subset in } X. \textit{ Let} \\ f : A \to Y \textit{ be an equivariant map. Under which conditions does there} \\ \textit{exist an equivariant extension of } f \textit{ over } X \textit{ (resp. over a } G\textit{-invariant} \\ \textit{neighborhood of } A \textit{ in } X)? \end{cases}$$

Recall the principle of constructing equivariant maps via *induction over orbit types* (see [43]). Suppose G acts on X with finitely many orbit types $\mathcal{J}(X) = \{(H_1), (H_2), \dots, (H_k)\}$, where $\mathcal{J}(X)$ is equipped with the partial order such that $(H_i) \leqslant (H_l)$ implies $i \geqslant l$ (cf. (10)). Assume that $Y^{H_l} \neq \emptyset$ for $l = 1, \dots, k$, which is a necessary condition for the existence of equivariant maps from X to Y. Define a filtration of X by closed (in X) G-invariant subsets

$$A = X_0 \subset X_1 \subset X_2 \subset \cdots \subset X_k = X,$$

where, for $l \geqslant 1$,

$$X_l := \bigl\{x \in X\colon\ (G_x) = (H_j) \text{ for some } j \leqslant l\bigr\} \cup A.$$

Suppose that $f_{l-1} : X_{l-1} \to Y$ is an equivariant map for some $l \geqslant 1$. We are interested in the existence of an equivariant extension $f_l : X_l \to Y$ of the map f_{l-1}. It is well-known (cf. [43]) that if the map $f_{l-1}^{H_l} : X_{l-1}^{H_l} \to Y^{H_l}$ admits a $W(H_l)$-equivariant extension $s : X_l^{H_l} \to Y^{H_l}$, then there exists a unique G-equivariant extension $f_l : X_l \to Y$ such that $f_{l}{}_{|X_l^{H_l}} = s$. Therefore, we arrive at the following question: *When does there exist a* $W(H_l)$*-equivariant extension* s*?* Notice that $W(H_l)$ acts freely on $X_l^{H_l} \setminus X_{l-1}^{H_l}$, thus the general problem (P_A) can be reduced to the following one:

$$(P_B)\quad \begin{cases} \textit{Let } X, A, Y \textit{ and } f \textit{ be as above and assume that } G \textit{ acts freely on } X \setminus A. \\ \textit{Find a } G\textit{-equivariant extension of } f \textit{ over } X \textit{ (resp. over a } G\textit{-invariant} \\ \textit{neighborhood of } A \textit{ in } X). \end{cases}$$

Fundamental domains The key to the extension results we are looking for is the following notion.

DEFINITION 3.1. Let a topological group Q act on a finite-dimensional metric space X. Let $D_o \subset X$ be open in its closure D. Then, D is said to be a *fundamental domain* if the following conditions are satisfied:

- (i) $Q(D) = X$;
- (ii) $g(D_o) \cap h(D_o) = \emptyset$ for $g, h \in Q$, $g \neq h$;
- (iii) $X \setminus Q(D_o) = Q(D \setminus D_o)$;
- (iv) $\dim D = \dim X/Q$, $\dim(D \setminus D_o) < \dim D$, $\dim Q(D \setminus D_o) < \dim X$, where dim stands for the covering dimension.

It turns out that

THEOREM 3.2. (Cf. [99].) *Let G be a compact Lie group and X be a finite-dimensional metric G-space on which G acts freely. Then, a fundamental domain $D \subset X$ always exists.*

IDEA OF THE PROOF. Since G is a compact Lie group acting freely,

- (a) the orbit map $p : X \to X/G$ is the fiber bundle projection (cf. Gleason lemma);
- (b) X/G is metrizable (cf., for instance, [99]);
- (c) $\dim X/G = \dim X - \dim G$ (cf. [120]).

Using (a)–(c), one can construct $T_o \subset X/G$ such that:

- (α) T_o is dense in X/G;
- (β) T_o is open in X/G;
- (γ) $\dim((X/G) \setminus T_o) < \dim X/G$;
- (δ) the fiber bundle p is trivial over T_o.

Fix a trivialization $\psi : p^{-1}(T_o) \to G \times T_o$ and put $D_o := \psi^{-1}(\{1\} \times T_o)$. Then, $D = \overline{D_o}$ is the fundamental domain. □

Equivariant Kuratowski–Dugundji theorem Let us return to problem (P_B) (recall that we assume $X \setminus A$ is a free G-subspace). By Theorem 3.2, there exists a fundamental domain $D^{(0)} \subset L^{(0)} := X \setminus A$. Let $D_o^{(0)}$ be the corresponding open subset of $D^{(0)}$ satisfying the conditions (ii)–(iv) of Definition 3.1, and let $X^{(1)} := A \cup G(D^{(0)} \setminus D_o^{(0)})$, $L^{(1)} := X^{(1)} \setminus A$. Now, by applying Theorem 3.2 to $X^{(1)} \setminus A$, we obtain $X^{(2)}$ and $L^{(2)}$, etc. Consequently, by following the same steps, we obtain a closed finite G-invariant filtration

$$X = X^{(0)} \supset X^{(1)} \supset X^{(2)} \supset \cdots \supset X^{(r)} = A.$$

PROPOSITION 3.3. (Cf. [99].) *Under the above assumptions, any G-equivariant map $A \to Y$ extends over X if for all $i \geqslant 1$, any equivariant map $X^{(i)} \to Y$ has a* (*non-equivariant*) *extension over $X^{(i)} \cup D^{(i-1)}$.*

It should be pointed out that Proposition 3.3 together with the induction over orbit types reduces the equivariant extension problem to the non-equivariant one. For example, combining Proposition 3.3 with the classical Kuratowski–Dugundji theorem (see, for example, [99]), one can easily establish the corresponding version of this result for equivariant maps.

THEOREM 3.4. (Cf. [99].) *Let V be a finite-dimensional G-representation,* $Y := V \setminus \{0\}$, *X a G-space and $A \subset X$ a closed invariant subset in X with $\mathcal{J}(X \setminus A) = \{(H_1), \dots, (H_k)\}$. Let $f : A \to Y$ be a G-equivariant map. Then*:

(i) *There always exists a G-equivariant extension of f over a G-invariant neighborhood of A in X;*

(ii) *Assume that* $\dim V^{H_l} = n_l$ *for $l = 1, \dots, k$ and* $\dim(X_{(H_l)} \setminus A)/G < n_l$ *for all $l = 1, \dots, k$. Then f extends equivariantly over X.*

Under the same assumptions on X, A and V as in Problem (P_A), we say that a G-equivariant map $\mathfrak{h} : [0, 1] \times X \to V$ (where G will always be assumed to act trivially on $[0, 1]$) is a *G-homotopy* on X between $f_0 := \mathfrak{h}(0, \cdot)$ and $f_1 := \mathfrak{h}(1, \cdot)$.

In applications one is often interested in constructing G-equivariant extensions of homotopies without zeros. We have the following immediate consequence of Theorem 3.4.

COROLLARY 3.5. *Under the same assumptions on X, A and V as in Theorem* 3.4, *if* $\dim(X_{(H_l)} \setminus A)/G < n_l - 1$ *for all $l = 1, \dots, k$, then every G-equivariant homotopy $\mathfrak{h} : [0, 1] \times A \to Y$ has an equivariant extension over* $[0, 1] \times X$.

Regular fundamental domains To make the equivariant extension techniques based on the use of fundamental domains compatible with an appropriate equivariant degree theory, a more careful analysis of a geometry of a fundamental domain is needed.

DEFINITION 3.6. Under the notations of Definition 3.1, assume there exists an open *contractible* subset $T_0 \subset X/Q$ such that the natural projection $p : X \to X/Q$ induces the homeomorphism

$$(p_{|D_o})^{-1} : T_o \to D_o. \tag{24}$$

Then, D (resp. (24)) is called a *regular fundamental domain* (resp. *lifting homeomorphism*).

THEOREM 3.7. *Let X be a G-manifold on which a compact Lie group G acts freely. Let X/G be connected. Then, there always exists a regular fundamental domain.*

The proof of Theorem 3.7 uses the same ideas as Theorem 3.2 combined with the following statement applied to X/G.

THEOREM 3.8. *Let M be a smooth connected n-dimensional manifold* (*in general noncompact*). *Take a smooth countable triangulation of M. Then, there always exists a subset T_o of M satisfying the following conditions*:

(i) *T_o is open in M;*

(ii) *T_o is dense in M;*

(iii) *T_o is contractible*;

(iv) *$M \setminus T_o$ is contained in the $n - 1$-dimensional skeleton.*

Equivariant Dugundji theorem For several reasons we will also use the following equivariant analogue of the Dugundji theorem.

PROPOSITION 3.9. (Cf. [3,4].) *Let X be a metric G-space, $A \subset X$ a closed invariant subspace, E an isometric Banach G-representation, $C \subset E$ a convex closed invariant subset and $f : A \to C$ an equivariant map. Then, there exists an equivariant extension $F : X \to C$ of f.*

In particular, given two closed disjoint and invariant subsets A and B of a metric G-space X, by applying Proposition 3.9, one can construct an invariant Urysohn function from X to $[0, 1]$ (with the trivial G-action on $[0, 1]$), which in turn allows to obtain small invariant (disjoint) neighborhoods around A and B.

3.2. *Analysis behind the construction: Regular normal approximations*

Throughout this subsection, G stands for a compact Lie group, V for an orthogonal G-representation, $\Omega \subset \mathbb{R} \oplus V$ is an open bounded G-invariant subset and $f : \mathbb{R} \oplus V \to V$ an equivariant map.

DEFINITION 3.10. Given an orthogonal G-representation V and a bounded open invariant set $\Omega \subset \mathbb{R} \oplus V$, an equivariant map $f : \mathbb{R} \oplus V \to V$ is called Ω-*admissible* if $f(x) \neq 0$ for all $x \in \partial\Omega$ (in such a case we will call (f, Ω) an *admissible pair*). Similarly, one can define an Ω-*admissible homotopy*.

The “differential viewpoint” that we follow to assign the twisted equivariant degree to an Ω-admissible map, amounts to choosing “nice” representatives of (equivariant) homotopy classes satisfying reasonable regularity/transversality condition. However, such a choice should be determined by the following two observations:

(i) Since we are dealing with group actions admitting *several* orbit types, usual transversality conditions are not reasonable. Moreover, even in the case of one orbit type, the equivariance may be in “conflict” with regularity due to the restriction requirements on the dimensions of the orbits of zeros.

(ii) Any concept of “nice” representatives should provide a way to separate the sets of zeros belonging to different orbit types (in particular, to be compatible with the principle of constructing equivariant maps via induction over orbit types), and, in addition, to be “stable” with respect to the suspension procedure (in particular, to allow a passage to infinite dimensions).

The observation (ii) leads to a concept of *normal* maps, while (i) leads to a special *regularity* requirement restricted to separate orbit types.

Normality Recall that for every (closed) subgroup $H \subset G$, the set $\Omega_{(H)}$ is a G-submanifold of Ω. In particular, one can speak about the normal G-vector bundle around $\Omega_{(H)}$.

DEFINITION 3.11. (Cf. [60,96,99].) An Ω-admissible map $f : \mathbb{R} \oplus V \to V$ is called *normal* in Ω if for every $(H) \in \mathcal{J}(\Omega)$ and every

$$x \in f^{-1}(0) \cap \Omega_H,$$

the following (H)-*normality* condition at x is satisfied: *There exists* $\delta_x > 0$ *such that for all* $w \in \nu_x(\Omega_{(H)})$ *with* $\|w\| < \delta_x$,

$$f(x + w) = f(x) + w = w$$

(here $\nu_x(\cdot)$ stands for the normal slice).

Similarly, an Ω-admissible G-homotopy $h : [0, 1] \times (\mathbb{R} \oplus V) \to V$ is called a *normal homotopy* in Ω, if for every $(H) \in \mathcal{J}(\Omega)$ and for every $(t, x) \in h^{-1}(0) \cap ([0, 1] \times \Omega_H)$, the following (H)-*normality* condition at (t, x) is satisfied: There exists $\delta_{(t,x)} > 0$ such that for all $w \in \nu_{(t,x)}([0, 1] \times \Omega_{(H)})$ with $\|w\| < \delta_{(t,x)}$,

$$h(t, x + w) = h(t, x) + w = w. \tag{25}$$

From Definition 3.11, it follows immediately (cf. observation (ii) above)

PROPOSITION 3.12. *If* $f : \mathbb{R} \oplus V \to V$ *is normal in* Ω, *then*

$$\overline{\left(f^{-1}(0) \cap \Omega_{(K)}\right)} \cap \overline{\left(f^{-1}(0) \cap \Omega_{(H)}\right)} = \emptyset \quad \textit{for all } (K), (H) \in J(\Omega), \tag{26}$$

provided $(K) \neq (H)$.

Regular normality Introduce the following

DEFINITION 3.13. (Cf. [60,96,99].) Let $f : \mathbb{R} \oplus V \to V$ be and Ω-admissible G-equivariant map. We say that f is a *regular normal* map in Ω if:

(i) f is of class C^1;
(ii) f is normal in Ω;
(iii) for every $(H) \in \mathcal{J}(f^{-1}(0) \cap \Omega)$, zero is a regular value of $f_H := f|_{\Omega_H} : \Omega_H \to V^H$.

Similarly, one can define the notion of *regular normal* homotopy.

Using induction over orbit types, Proposition 2.13 and Theorem 2.14, one can establish

PROPOSITION 3.14. (See [60,96,99].) *Each* Ω-*admissible map* $f : \mathbb{R} \oplus V \to V$ *admits an arbitrarily close regular normal approximation.*

3.3. *Algebra behind the construction: Twisted groups and Burnside modules*

Hereafter, we use the following notations: Γ stands for a compact Lie group and $G := \Gamma \times S^1$, where S^1 is the unit circle in $\mathbb{C}$.

The twisted equivariant degree we are going to construct takes its values in a certain module (denoted by $A_1^t(G)$) over the Burnside ring $A(\Gamma)$. In this subsection, we briefly discuss generators and multiplication structure of $A_1^t(G)$.

Numbers $n(L,H)$ We start our exposition of algebraic ideas underlying the construction of twisted equivariant degree with introducing certain integers intimately related to the module $A_1^t(G)$. Moreover, as we will see later on, these numbers play a substantial role in the computational formulae for the twisted degree.

Given two closed subgroups $L \subset H$ of a compact Lie group Q, define the set (cf. [74,99])

$$N(L,H) = \{g \in Q\colon\ gLg^{-1} \subset H\} \tag{27}$$

and put

$$n(L,H) := \left|\frac{N(L,H)}{N(H)}\right|, \tag{28}$$

where the symbol $|X|$ stands for the cardinality of the set X.

It turns out that

PROPOSITION 3.15. *Let $L \subset H$ be two closed subgroups of a compact Lie group such that* $\dim W(L) = \dim W(H)$. *Then, the number $n(L,H)$ is finite.*

The above statement can be easily proved using the following well-known

PROPOSITION 3.16. (Cf. [26], Corollary 5.7.) *Let $L \subset H$ be two closed subgroups of the compact Lie group Q. Then, the orbit space*

$$\frac{(Q/H)^L}{W(L)} \quad ((Q/H)^L \text{ is considered as the left } W(L)\text{-space})$$

is finite.

Observe that the number $n(L,H)$ (where $L \subset H$ are two closed subgroups of Q with $\dim W(H) = \dim W(L)$) has a very simple geometric interpretation provided by the following

LEMMA 3.17. *Let L and H be two subgroups of a compact Lie group Q such that $L \subset H$ and* $\dim W(H) = \dim W(L)$. *Then, $n(L,H)$ represents the number of different subgroups $\widetilde{H}$ in the conjugacy class (H) such that $L \subset \widetilde{H}$. In particular, if V is an orthogonal Q-representation such that (L), $(H) \in \mathcal{J}(V)$, then $V^L \cap V_{(H)}$ is a disjoint union of exactly $m = n(L,H)$ sets V_{H_j}, $j = 1,2,\dots,m$, satisfying $(H_j) = (H)$.*

NOTATION. In what follows, in the case of two orbit types (L) and (H) such that $(L) \leqslant (H)$ (with the order relation defined by (10)), we will assume that the number $n(L, H)$ corresponds to representatives L and H such that $L \subset H$. In the case the orbit types (L) and (H) are not comparable with respect to the order relation (10), we will simply put $n(L, H) = 0$.

REMARK 3.18. It should be pointed out that the numbers $n(L, H)$ are essentially of non-abelian nature: if Q is an abelian compact Lie group and $L \subset H \subset Q$ are (closed) subgroups, then $n(L, H) \equiv 1$. In a certain sense, the numbers $n(L, H)$ demonstrate a principal difference between the (twisted) equivariant degree theory for non-abelian groups from that for abelian ones.

Burnside ring $A(\Gamma)$ Recall some basic facts related to the Burnside Ring $A(\Gamma)$ of the compact Lie group Γ.

Denote by $\Phi_0(\Gamma)$ the set of conjugacy classes (H) for $H \subset \Gamma$, such that $W(H) = N(H)/H$ is finite, i.e. $\dim W(H) = 0$. Let $A(\Gamma)$ be the free abelian group generated by $(H) \in \Phi_0(\Gamma)$. There is a *multiplication* operation on $A(\Gamma)$ which induces a structure of a ring with identity on $A(\Gamma)$. In order to define the multiplication operation, observe that

$$\begin{aligned}(\Gamma/H \times \Gamma/K)_{(L)}/\,\Gamma &\cong (\Gamma/H \times \Gamma/K)_L/N(L)\\ &\subset (\Gamma/H \times \Gamma/K)^L/N(L)\\ &= (\Gamma/H^L \times \Gamma/K^L)/W(L)\\ &= \left(\frac{N(L,H)}{H} \times \frac{N(L,K)}{K}\right)\Big/ W(L).\end{aligned}$$

Since, by Proposition 3.16, the spaces Γ/H^L and Γ/K^L consist of finitely many $W(L)$-orbits and, by assumption, $W(L)$ is finite, one obtains that Γ/H^L and Γ/K^L are finite. Consequently the set $(\Gamma/H \times \Gamma/K)_{(L)}/\,\Gamma$ is finite.

The multiplication table of the generators (H) is given by the relation

$$(H) \cdot (K) = \sum_{(L) \in \Phi_0(\Gamma)} n_L(H, K)(L) \tag{29}$$

where $n_L(H, K)$ denotes the number of elements in the set $(\Gamma/H \times \Gamma/K)_{(L)}/\,\Gamma$, i.e.

$$n_L(H, K) := \left|(\Gamma/H \times \Gamma/K)_{(L)}/\,\Gamma\right|,$$

where we denote by $|X|$ the number of elements in the set X. In other words, the number $n_L(H, K)$ represents the number of the orbits of the orbit type (L) contained in the space $\Gamma/H \times \Gamma/K$.

The ring $A(\Gamma)$ is called the *Burnside Ring* of Γ. We refer to [93] for more details and proofs related to the above definition of the Burnside Ring.

The computations of the multiplication table for $A(\Gamma)$ can be effectively conducted using a simple recurrence formula:

$$n_L(H,K) = \frac{n(L,H)|W(H)|n(L,K)|W(K)| - \sum_{(\tilde{L})>(L)} n(L,\tilde{L}) n_{\tilde{L}} |W(\tilde{L})|}{|W(L)|}, \tag{30}$$

where $|X|$ denotes the number of elements in the set X.

Twisted Subgroups of $G = \Gamma \times S^1$ Here, given a compact Lie group Γ, we briefly discuss generators of the $\mathbb{Z}$-module $A_1^t(G)$, where $G := \Gamma \times S^1$. To this end, we need to classify subgroups H of G.

Consider the following diagram

$$\begin{tikzcd}
& H \arrow[dl, "\pi_1"'] \arrow[dr, "\pi_2"] & \\
\Gamma & & S^1
\end{tikzcd}$$

where π_1 and π_2 are projections (homomorphisms) on Γ and S^1 respectively. Let $K := \pi_1(H)$ and consider $\ker \pi_1 = H \cap \{e\} \times S^1$, where e denotes the neutral element of Γ. If $\ker \pi_1 = \{e\} \times S^1$, then simply $H = K \times S^1$, i.e. H is a "product" subgroup. Otherwise $\ker \pi_1 = \{e\} \times \mathbb{Z}_l$, for some $l \geqslant 1$, and in this case, we are dealing with "twisted" subgroups. In the second case, we still have that $H/\ker \pi_1 \subset \Gamma \times S^1$, thus we can consider the diagram below.

$$\begin{tikzcd}
& H \arrow[d, "\mu_l"] & \\
& H/\ker\pi_1 \arrow[dl, "\pi_1"'] \arrow[dr, "\pi_2"] & \\
K \arrow[rr, dotted, "\varphi"] & & S^1
\end{tikzcd}$$

Since $\pi_1 : H/\ker \pi_1 \to K$ is one-to-one and onto, we can define the homomorphism $\varphi := \pi_2 \circ \pi_1^{-1} : K \to S^1$, and consequently the subgroup $H/\ker \pi_1$ is the graph of φ, i.e.

$$H/\ker \pi_1 := \left\{(k,z) \in K \times S^1 \colon \varphi(k) = z\right\},$$

and since the subgroup H is the inverse image $\mu_l^{-1}(H/\ker \pi_1)$, we obtain:

$$H = \left\{(k,z) \in K \times S^1 \colon \varphi(k) = z^l\right\}.$$

In this case, we call the subgroup H a *twisted* (by the homomorphism $\varphi : K \to S^1$) *l-folded* subgroup which is denoted by $K^{\varphi,l}$ (for $l = 1$ we simply write K^{φ}). It is easy to see that each (closed) subgroup $K \subset \Gamma \cong \Gamma \times \{1\} \subset G$, where 1 is the unit in S^1, is (trivially) twisted by the homomorphism $\varphi : K \to S^1$ defined as $\varphi(x) \equiv 1$.

Consider a twisted l-folded subgroup $H = K^{\varphi,l}$ and the normalizer $N(H)$ of the group H. Notice that

$$\begin{aligned} N(H) = N(K^{\varphi,l}) &= \{(\gamma, w) \in \Gamma \times S^1\colon\ (\gamma, w)K^{\varphi,l}(\gamma, w)^{-1} = K^{\varphi,l}\} \\ &= \{(\gamma, w) \in \Gamma \times S^1\colon\ \gamma k \gamma^{-1} \in K,\ \varphi(\gamma k \gamma^{-1}) = \varphi(k)\ \forall k \in K\} \\ &= \{\gamma \in N(K)\colon\ \varphi(\gamma k \gamma^{-1}) = \varphi(k)\ \forall k \in K\} \times S^1 =\colon N_o \times S^1. \end{aligned}$$

Consequently,

$$\dim W(H) = \dim N_o/K + 1 \leqslant \dim W_\Gamma(K) + 1,$$

where $W_\Gamma(\cdot)$ stands for the Weyl group in Γ. In the case $(K) \in \Phi_0(\Gamma)$, i.e. $\dim W_\Gamma(K) = 0$, we have that $\dim W(H) = 1$.

REMARK 3.19. Notice that if $H = K^{\varphi,l}$ is a twisted subgroup and $(\widetilde{H}) \leqslant (H)$, then $\widetilde{H}$ is also a twisted subgroup. In particular, every subgroup $H' \in (H)$ is twisted. Consequently, it makes sense to talk about the lattice of the conjugacy classes of twisted subgroups in G. Moreover, if $\dim W_\Gamma(K) = 0$ and $L^{\psi,l'}$ is a twisted subgroup such that $(L^{\psi,l'}) \geqslant (K^{\varphi,l})$, then it is easy to see that $\dim W_\Gamma(L) = 0$.

With these preliminaries on hands, introduce the following

DEFINITION 3.20. Denote by $\Phi_1^t(G)$ the set of all conjugacy classes of the φ-twisted l-folded subgroups $H = K^{\varphi,l}$, $l = 1, 2, \ldots$, such that the Weyl group $W_\Gamma(K)$ of K in Γ is finite (i.e. $\dim W_\Gamma(K) = 0$). We call any element from $\Phi_1^t(G)$ a *twisted conjugacy class.*

In what follows, twisted conjugacy classes will perform as generators of the module $A_1^t(G)$. Clearly, the construction of twisted subgroups provides (algebraic) features allowing to classify symmetric properties of periodic solutions to dynamical systems. What is, probably, less obvious, twisted subgroups are intimately connected to *orientability* properties of the corresponding to them Weyl groups, which, in turn is extremely important for the construction of the (twisted) equivariant degree.

To be more specific, let Q be a compact Lie group and M a Q-manifold. Take $x \in M$ with the isotropy $Q_x = H$. By passing to the $W(H)$-manifold M^H, we arrive at the following question: *does the orbit $N := W(H)(x)$ admit a natural $W(H)$-invariant orientation?* Since $W(H)$ is an orientable manifold, one can choose an orientation $\mathfrak{o}_{W(H)}$ on $W(H)$ and use the action of $W(H)$ on M^H to induce an orientation $\mathfrak{o}$ on N via the diffeomorphism $\mu_{x_o}\colon W(H) \to N$ given by $\mu_{x_o}(h) := hx_o$, $h \in W(H)$, for a certain distinguished point $x_o \in N$. Clearly, in order to this construction to be natural, the orientation of N obtained in this way should not depend on a choice of the point x_o. However, this property is satisfied only if the orientation $\mathfrak{o}_{W(H)}$ is invariant with respect to *right* translations on $W(H)$. On the other hand, the constructed orientation $\mathfrak{o}$ of the orbit N is $W(H)$-invariant if and only if $\mathfrak{o}_{W(H)}$ is invariant with respect to *left* translations on $W(H)$. Consequently, we obtain that an orbit N admits a natural $W(H)$-invariant orientation if and only if $W(H)$ admits an orientation which is invariant with respect to *both* left and right translations (in this case, $W(H)$ is called *bi-orientable*).

Clearly, any reasonable equivariant degree theory allowing an "algebraic count" of orbits of periodic solutions should deal with the above mentioned *natural* $W(H)$-invariant orientation on orbits in question (or, equivalently, with bi-orientable groups $W(H)$). It is easy to see that if $W(H)$ is finite, Abelian or contains an odd number of connected components, then it is bi-orientable. On the other hand, the group O(2) presents an example of the non-bi-orientable group. Our choice of the module $A_1^t(G)$ for the range of values of the (twisted) equivariant degree is essentially based on the following

PROPOSITION 3.21. *Let Γ be a compact Lie group, $G := \Gamma \times S^1$ and $H = K^{\varphi,l}$ a twisted subgroup of G such that $(H) \in \Phi_1^t(G)$. Then*:

(i) *the connected component of $1 \in W(H)$ can be canonically identified with S^1*;

(ii) *the Weyl group $W(H)$ of H in G is bi-orientable and can be equipped with the natural orientation induced from S^1.*

$A(\Gamma)$-module $A_1^t(G)$ Take the set $\Phi_1^t(G)$ introduced in Definition 3.20 and consider the free $\mathbb{Z}$-module $A_1^t(G) := \mathbb{Z}[\Phi_1^t(G)]$. Using Proposition 3.16 and the (finiteness) argument similar to that for the Burnside ring (cf. formula (29)), one can easily establish the following

THEOREM 3.22. *There is a "multiplication" function $\cdot : A(\Gamma) \times A_1^t(G) \to A_1^t(G)$ defined on the generators $(K) \in \Phi_0(\Gamma)$ and $(H^{\varphi,l}) \in \Phi_1^t(G)$ as follows*:

$$(K) \cdot (H^{\varphi,l}) = \sum_{(L)} n_L (L^{\varphi,l}), \tag{31}$$

where the summation is taken over all subgroups L such that $W(L)$ is finite, $L = \gamma^{-1} K \gamma \cap H$ for some $\gamma \in \Gamma$ and

$$n_L = \left| \left(\frac{G}{K \times S^1} \times \frac{G}{H^{\varphi,l}} \right)_{(L^{\varphi,l})} \Big/ G \right|.$$

The $\mathbb{Z}$-module $A_1^t(G)$ equipped with the multiplication "$\cdot$" becomes an $A(\Gamma)$-module.

Below we describe the process one can follow to establish the multiplication tables for the $A(\Gamma)$-module $A_1^t(G)$, based on the same idea of a recurrence formula (30).

Let $(K) \in \Phi_0(\Gamma)$ be a generator of $A(\Gamma)$ and $(H^{\varphi,l}) \in \Phi_1^t(G)$ a generator of $A_1^t(G)$. In order to compute the coefficients n_L given in formula (31), apply the following recurrence formula

$$n_L = \Bigg[n(L,K) \big| W(K) \big| n(L^{\varphi,l}, H^{\varphi,l}) \left| \frac{W(H^{\varphi,l})}{S^1} \right|$$

$$- \sum_{(\tilde{L})>(L)} n(L^{\varphi,l}, \tilde{L}^{\varphi,l}) n_{\tilde{L}} \left| \frac{W(\tilde{L}^{\varphi,l})}{S^1} \right| \Bigg] \Bigg/ \left| \frac{W(L^{\varphi,l})}{S^1} \right| \tag{32}$$

where for a set Y, $|Y|$ denotes the number of elements in Y.

REMARK 3.23. Notice that the multiplication formulae for conjugacy classes of trivially twisted subgroups $(H) \in \Phi_1^t(G)$ (i.e. $H = H^{\varphi,1}$ with $\varphi \equiv 1$), where $(H) \in \Phi_0(\Gamma)$, coincide with the multiplication formulae for the Burnside ring $A(\Gamma)$. That means, the multiplication formulae for the Burnside ring are contained in the $A(\Gamma)$-module multiplication formulae for $A_1^t(G)$.

REMARK 3.24. Let us point out that the formula (32) allows us to implement the multiplication tables for the $A(\Gamma)$-module $A_1^t(G)$ into a computer software, which can be effectively used for the computations of the twisted degree.

3.4. *Construction*

We are now in a position to present the construction of twisted equivariant degree.

We start with the regular normal case, i.e. take an orthogonal G-representation V, open bounded G-invariant subset $\Omega \subset \mathbb{R} \oplus V$ and an Ω-admissible *regular normal* map $f : \mathbb{R} \oplus V \to V$. Fix $(H) \in \Phi_1^t(G, \Omega) := \{(H) \in \mathcal{J}(\Omega)\colon\ (H) \in \Phi_1^t(G)\}$. By Theorem 2.14(v), Ω_H is a free $W(H)$-manifold. Assuming, without loss of generality, that $\Omega_H/W(H)$ is connected, and using Theorem 3.7, one can find a regular fundamental domain D on Ω_H with the lifting homeomorphism

$$\xi := (p_{|D_o})^{-1} : T_o \to D_o$$

(cf. Definitions 3.1 and 3.6). Moreover, since f is normal, it satisfies the condition (26). Hence, one can choose D in such a way that

$$f_H^{-1}(0) \cap (D \setminus D_o) = \emptyset, \tag{33}$$

where $f_H := f|_{\Omega_H}$. Since f is regular normal, the set

$$p\bigl(f_H^{-1}(0) \cap D_o\bigr)$$

is finite, therefore, one can construct T_o providing

$$p\bigl(f_H^{-1}(0)\bigr) \subset T_o. \tag{34}$$

Since $\Omega_H/W(H)$ is a (smooth) manifold (see Theorem 2.14(v)) and T_o is open in $\Omega_H/W(H)$, T_o is a manifold as well. Since T_o is *contractible*, it is *orientable*. By assumption, $(H) \in \Phi_1^t(G)$, therefore, fix the natural orientation on $W(H)$ which is invariant with respect to both left and right translations (cf. Proposition 3.21). Also, fix an orientation on V^H inducing an orientation on $\mathbb{R} \oplus V^H$. By bi-orientability of $W(H)$, for every $x \in T_o$, the orbit $N := W(H)(\xi x)$ has a natural $W(H)$-invariant orientation. Therefore, we can assume that the orientation on T_o is chosen in such a way that for *all* $x \in T_o$, we have that the orientation on $\mathbb{R} \oplus V^H$ is obtained from the orientation on D_o followed by the orientation on N, and the lifting homeomorphism $\xi : T_o \to D_o$ preserves the orientation.

Put

$$n_H = n_H(f) := \deg(f_H \circ \xi, T_o) \tag{35}$$

(here "deg" denotes the (local) Brouwer degree with respect to zero (this degree is correctly defined according to (33) and (34))).

Furthermore, take $A_1^t(G)$ and define the twisted equivariant degree $G\text{-Deg}^t(f, \Omega)$ by:

$$G\text{-Deg}^t(f, \Omega) = \sum_{(H) \in \Phi_1^t(G, \Omega)} n_H(H), \tag{36}$$

where n_H is defined by (35).

If now $f : \mathbb{R} \oplus V \to V$ is an *arbitrary* Ω-admissible map (in general, neither normal nor regular), choose a regular normal Ω-admissible map $g : \mathbb{R} \oplus V \to V$ close to f (see Proposition 3.14) and put

$$G\text{-Deg}^t(f, \Omega) := G\text{-Deg}^t(g, \Omega). \tag{37}$$

REMARK 3.25. Some comments related to the definition of twisted degree are in order.

(i) To some extent, the bi-orientability of $W(H)$ is used to define an "index of an orbit" ("local twisted degree"), while the contractibility of T_o allows a correct definition on the whole T_o ("global twisted degree").

(ii) If we choose an orientation on D_o in such a way that ξ preserves it, then $\deg(f_H, D_o)$ is correctly defined and coincides with $\deg(f_H \circ \xi, T_o)$. In this sense, one can think of $n_H(f)$ as a "degree of f_H on a fundamental domain D".

(iii) It is possible to show that the definition of twisted degree given by (35)–(37) is independent of a choice of fundamental domains as well as regular normal approximations.

3.5. *Axiomatic approach to twisted degree*

Basic properties The twisted degree defined above satisfies all the standard properties required from any reasonable "degree theory". To see that, we need the following

DEFINITION 3.26. Let V be an orthogonal G-representation with $G = \Gamma \times S^1$ and $f : \mathbb{R} \oplus V \to V$ a regular normal map such that $f(x_o) = 0$ with $G_{x_o} = H$ and $(H) \in \Phi_1^t(G, V)$. Let

$U_{G(x_o)}$ be a G-invariant tubular neighborhood around $G(x_o)$ such that $f^{-1}(0) \cap U_{G(x_o)} = G(x_o)$ (cf. Proposition 2.13). Then, f is called a *tubular map*.

Next, fix the natural orientation on $W(H)$ which is invariant with respect to both left and right translations. Also, fix an orientation on V^H inducing an orientation on $\mathbb{R} \oplus V^H$. By bi-orientability of $W(H)$, choose the natural orientation on the orbit $W(H)(x_o)$ and assume that the orientation on the normal slice $\nu_{x_o} := \nu_{x_o}(W(H)(x_o))$ in $\mathbb{R} \oplus V^H$ is oriented in such a way that the orientation on $\mathbb{R} \oplus V^H$ is obtained from the orientation on ν_{x_o} followed by the orientation on $W(H)(x_o)$. Then, we call $n_{x_o} = \operatorname{sign} \det Df^H(x_o)|_{\nu_{x_o}}$ the *local index* of f at x_o in $U_{G(x_o)}$ (here $f^H := f|_{\Omega^H}$ and "D" stands for the differential).

PROPOSITION 3.27. *Let V be an orthogonal G-representation with $G = \Gamma \times S^1$, $\Omega \subset \mathbb{R} \oplus V$ an open bounded invariant subset and $f : \mathbb{R} \oplus V \to V$ an equivariant Ω-admissible map. Then, the twisted equivariant degree defined by* (35)–(37) *satisfies the following properties*:

(P1) (Existence) *If G-$\mathrm{Deg}^t(f, \Omega) = \sum_{(H)} n_H(H)$ is such that $n_{H_o} \neq 0$ for some $(H_o) \in \Phi_1^t(G, \Omega)$, then there exists $x \in \Omega$ with $f(x) = 0$ and $G_x \supset H_o$.*

(P2) (Additivity) *Assume that Ω_1 and Ω_2 are two G-invariant open disjoint subsets of Ω such that $f^{-1}(0) \cap \Omega \subset \Omega_1 \cup \Omega_2$. Then,*

$$G\text{-}\mathrm{Deg}^t(f, \Omega) = G\text{-}\mathrm{Deg}^t(f, \Omega_1) + G\text{-}\mathrm{Deg}^t(f, \Omega_2).$$

(P3) (Homotopy) *Suppose $h : [0,1] \times \mathbb{R} \oplus V \to V$ is an Ω-admissible G-equivariant homotopy. Then,*

$$G\text{-}\mathrm{Deg}^t(h_t, \Omega) = \text{const}$$

(*here $h_t := h(t, \cdot, \cdot)$, $t \in [0,1]$*).

(P4) (Suspension) *Suppose that W is another orthogonal G-representation and let U be an open bounded G-invariant neighborhood of* 0 *in W. Then,*

$$G\text{-}\mathrm{Deg}^t(f \times \mathrm{Id}, \Omega \times U) = G\text{-}\mathrm{Deg}^t(f, \Omega).$$

(P5) (Normalization) *Suppose f is a tubular map around $G(x_o)$ with $H := G_{x_o}$ and the local index n_{x_o} of f at x_o in a tubular neighborhood $U_{G(x_o)}$. Then,*

$$G\text{-}\mathrm{Deg}^t(f, U_{G(x_o)}) = n_{x_o}(H).$$

(P6) (Elimination) *Suppose f is normal in Ω and $\Omega_H \cap f^{-1}(0) = \emptyset$ for every $(H) \in \Phi_1^t(G, \Omega)$. Then,*

$$G\text{-}\mathrm{Deg}^t(f, \Omega) = 0.$$

(P7) (Excision) *If $f^{-1}(0) \cap \Omega \subset \Omega_0$, where $\Omega_0 \subset \Omega$ is an open invariant subset, then*

$$G\text{-}\mathrm{Deg}^t(f, \Omega) = G\text{-}\mathrm{Deg}^t(f, \Omega_0).$$

(P8) (Hopf property) *Suppose that* $\Omega_H/W(H)$ *is connected for all* $(H) \in \Phi_1^t(G,\Omega)$ *and* $\Omega_K = \emptyset$ *for all* $(K) \notin \Phi_1^t(G,\Omega)$. *Let* $f, g : \mathbb{R} \oplus V \to V$ *be two* Ω*-admissible* G*-equivariant maps such that*

$$G\text{-Deg}^t(f,\Omega) = G\text{-Deg}^t(g,\Omega).$$

Then, f *and* g *are* G*-equivariantly homotopic by an* Ω*-admissible homotopy.*

PROOF. To establish properties (P1)–(P4), (P7) in the regular normal case, one should combine Proposition 3.12 and formulae (35), (36) with appropriate properties of the (local) Brouwer degree. In the general case, take regular normal approximations sufficiently close to f (resp. h) and use the standard compactness argument.

Property (P5) (resp. (P6)) follows immediately from the regular value definition of the Brouwer degree (resp. definition of the twisted degree).

To prove property (P8), assume (without loss of generality) that f and g are regular normal. Combining Proposition 3.12 with the classical Hopf Theorem (see, for instance, [44]) applied to appropriate fundamental domains, construct "local" homotopies between f and g around the corresponding zeros and extend the obtained homotopies by G-equivariance. Next, using Theorem 3.4 (see also Corollary 3.5), extend the previous "partial homotopy" over $\Omega \times [0,1]$. The latter homotopy may have "new" zeros which can be eliminated by using Proposition 3.9. □

REMARK 3.28. Following the same lines as above, one can associate with an open Γ-invariant bounded set $U \subset W$ (W is an orthogonal Γ-representation) and a continuous Γ-equivariant map $g : (U, \partial U) \to (W, W \setminus \{0\})$ the Γ-equivariant degree $\Gamma\text{-Deg}(g,U)$ taking its values in the Burnside ring $A(\Gamma)$ and satisfying the properties similar to (P1)–(P8) with obvious modifications (see [93] and [99] for more details).

Axiomatic approach The following result provides an axiomatic approach to the twisted degree theory.

THEOREM 3.29. *There exists a unique* $A_1^t(G)$*-valued function on the set of* Ω*-admissible* G*-equivariant maps and homotopies satisfying conditions* (P1)–(P6).

PROOF. The *existence* part of Theorem 3.29 is provided by Proposition 3.27. To prove the *uniqueness* part, assume $\overline{G\text{-Deg}^t}$ is another 'degree' satisfying (P1)–(P6). Take an arbitrary admissible pair (f,Ω). By homotopy property, f can be assumed to be regular normal. By additivity (i.e. excision) and elimination properties, we can assume that $\Omega \cap f^{-1}(0)$ contains only points of the orbit types $(H) \in \Phi_1^t(G)$. Since f is regular normal, the set $\Omega \cap f^{-1}(0)$ is composed of a finite number of G-orbits. Take tubular neighborhoods isolating the above orbits (this is doable, since we have finitely many zero orbits). By additivity property, $\overline{G\text{-Deg}^t}(f,\Omega)$ is equal to the sum of degrees of restrictions of f to the tubular neighborhoods. Finally, by normalization property, the orbits in question lead to "local indices", which implies

$$\overline{G\text{-Deg}^t}(f,\Omega) = G\text{-Deg}^t(f,\Omega).$$ □

Theorem 3.29 provides the application of the twisted degree without going into topological, analytical and algebraic roots underlying its construction – this is an obvious advantage of the axiomatic approach. In addition, this theorem can be extended to equivariant maps $\mathbb{R}^n \oplus V \to V$ with G replaced by $\Gamma \times T^n$, where T^n stands for the n-dimensional torus (such a setting naturally appears in multiparameter bifurcation problems). However, Theorem 3.29 amounts to the *normality* property (see (P5)–(P6)) which (being of great theoretical importance) is easy to formulate but difficult to achieve in practice.

Fortunately, in the setting relevant to our discussion, there is an effective way "to go around the normality problem", namely:

(i) to define the twisted degree for $G = S^1$ by a list of axioms (of course, equivalent to those presented in Proposition 3.27) with the normality property not being addressed whatsoever;

(ii) for an arbitrary $G = \Gamma \times S^1$, to obtain a formula canonically reducing the computations of G-degree to those for the S^1-degree and numbers $n(L, H)$.

3.6. S^1-*degree*

Assume $\Gamma = \{e\}$, i.e. $G = \{e\} \times S^1 \cong S^1$. Recall that any Abelian compact Lie group is bi-orientable. Therefore, $A_1^t(S^1) := A_1(S^1)$ is the free $\mathbb{Z}$-module generated by $(\mathbb{Z}_k)$, $k = 1, 2, 3 \dots$.

Take an S^1-representation V, an open S^1-invariant bounded set $\Omega \subset \mathbb{R} \oplus V$, and an Ω-admissible S^1-equivariant map $f : \mathbb{R} \oplus V \to V$. Then,

$$S^1\text{-Deg}(f, \Omega) = n_{k_1}(\mathbb{Z}_{k_1}) + \cdots + n_{k_r}(\mathbb{Z}_{k_r}), \tag{38}$$

where $n_{k_i} \in \mathbb{Z}$. To provide an axiomatic approach to the degree given by (38), we need two auxiliary constructions.

Two constructions

(i) *Basic maps*. Denote by $\mathcal{V}_k$, $k = 1, 2, 3, \dots$, the (non-trivial) k-th real irreducible S^1-representation, i.e. $\mathcal{V}_k$ is the space $\mathbb{R}^2 = \mathbb{C}$ with the S^1-action given by $\gamma z := \gamma^k \cdot z$, $\gamma \in S^1$, $z \in \mathbb{C}$, and define the set

$$^k\Omega := \left\{(t, z) \in \mathbb{R} \oplus \mathcal{V}_k \colon\ |t| < 1,\ \frac{1}{2} < |z| < 2\right\} \tag{39}$$

and $b : \mathbb{R} \oplus \mathcal{V}_k \to \mathcal{V}_k$ by

$$b(t, z) := \big(1 - |z| + \mathrm{i}t\big) \cdot z, \quad (t, z) \in \mathbb{R} \oplus \mathcal{V}_k, \tag{40}$$

where "$\cdot$" denotes the complex multiplication in $\mathcal{V}_k = \mathbb{C}$. Clearly, b is S^1-equivariant and $^k\Omega$-admissible. In what follows, b is called the k-th *basic map*.

(ii) *l-folding*. For every integer $l = 1, 2, 3, \dots$, define the homomorphism $\theta_l : S^1 \to S^1$ (called *l-folding*), by $\theta_l(\gamma) = \gamma^l$, $\gamma \in S^1$, and define the induced by θ_l homomorphism $\Theta_l : A_1(S^1) \to A_1(S^1)$, by

$$\Theta_l(\mathbb{Z}_k) := (\mathbb{Z}_{kl}), \quad k = 1, 2, 3, \dots,$$

i.e. $\Theta_l(\mathbb{Z}_k) = (\theta_l^{-1}(\mathbb{Z}_k))$, where $(\mathbb{Z}_k)$ are the free generators of $A_1(S^1)$.

If $f : \mathbb{R} \oplus V \to V$ is an Ω-admissible S^1-equivariant map for a certain open bounded S^1-invariant subset $\Omega \subset \mathbb{R} \oplus V$, then for every integer $l = 1, 2, 3, \dots$, define the *associated l-folded* S^1-representation ${}^l(V)$, which is the same vector space V with the S^1-action '$\cdot$' given by

$$\gamma \cdot v := \theta_l(\gamma)v = \gamma^l v, \quad \gamma \in S^1, \ v \in V.$$

Next, the map f considered from $\mathbb{R} \oplus {}^l(V)$ to ${}^l(V)$, is S^1-equivariant as well. The set Ω considered as an S^1-subset of $\mathbb{R} \oplus {}^l(V)$ is denoted by ${}^l(\Omega)$. In what follows, we will say that the pair $(f, {}^l(\Omega))$ is the *l-folded* admissible pair *associated* with (f, Ω).

Axiomatic approach to S^1-degree

THEOREM 3.30. *There exists a unique $A_1(S^1)$-valued function S^1-*Deg *defined on Ω-admissible S^1-equivariant maps and homotopies and satisfying properties* (P1)–(P4) (*with $G = S^1$*) *as well as the following ones*:

(P5′) (Normalization) *For the* 1*-st basic map $b : \mathbb{R} \oplus \mathcal{V}_1 \to \mathcal{V}_1$,*

$$S^1\text{-Deg}(b, {}^1\Omega) = (\mathbb{Z}_1).$$

(P6′) (Elimination) *If V is a trivial S^1-representation, then*

$$S^1\text{-Deg}(f, \Omega) = 0.$$

(F) (Folding) *Let ${}^l(V)$ be the l-folded representation associated with V, and $(f, {}^l(\Omega))$ the l-folded admissible pair associated with (f, Ω). Then,*

$$S^1\text{-Deg}(f, {}^l(\Omega)) = \Theta_l\big[S^1\text{-Deg}(f, \Omega)\big].$$

PROOF. The *existence* part of Theorem 3.30 is obvious. The *uniqueness* easily follows from

LEMMA 3.31. *Under the conditions and notations of Definition* 3.26, *assume $G = S^1$ and $G_{x_o} = \mathbb{Z}_{k_o}$. Assume that S^1-*Deg *is a function provided by Theorem* 3.30. *Then,*

$$S^1\text{-Deg}(f, \Omega) = n_{x_o}(\mathbb{Z}_{k_o}),$$

where n_{x_o} is the local index of f at x_o. □

3.7. *Computational techniques for twisted degree*

Statement of the problem The goal of this subsection is to show how the axiomatic approach described in the previous two sections, being combined with some additional techniques, allows to obtain twisted degree results for an important class of equivariant maps which naturally appear in the symmetric Hopf bifurcation problems.

We start with a simple observation that every S^1-representation admits the so-called *natural complex structure*, which turns out to be a convenient setting for the discussion of Hopf bifurcation problems and a natural way of describing the S^1-action to carry out certain computations. To be more specific, let V be an (orthogonal) S^1-representation with $V^{S^1} = \{0\}$. Then, one can define on V a complex structure sensitive to the S^1-action as follows. Assume, for a moment, that $V = \mathcal{V}_k$. Then, for $z \in \mathbb{C}$, put $z = \gamma|z|$, where $\gamma = \mathrm{e}^{\mathrm{i}\theta}$ for some $\theta \in [0, 2\pi)$. The complex multiplication of $v \in \mathcal{V}_k$ by the number z is defined by

$$z \cdot v := |z|\mathrm{e}^{\frac{\mathrm{i}\theta}{k}} v. \tag{41}$$

Suppose, further, that V is (in general) reducible, and we have the following S^1-isotypical decomposition (cf. (13) and (14)):

$$V = V_{k_1} \oplus V_{k_2} \oplus \cdots \oplus V_{k_s}, \tag{42}$$

where V_{k_j} is modeled on the irreducible S^1-representation $\mathcal{V}_{k_j}$, $j = 1, 2, \ldots, s$. Since for every j, $\mathcal{V}_{k_j}$ can be equipped with the complex structure according to (41), every isotypical component from (42) also admits such a structure. In this way, we obtain on V a complex structure which we call the *natural complex structure*.

Let Γ be a compact Lie group. As we will see later on, the problem of studying Γ-symmetric Hopf bifurcations in many cases can be reduced to the following one.

PROBLEM 3.32. Let $G = \Gamma \times S^1$ and let V be an orthogonal G-representation with $V^{S^1} = \{0\}$ (here S^1 is identified with $\{e\} \times S^1$). Suppose V (considered as the S^1-representation) is equipped with the natural complex structure and put

$$\mathcal{O} := \left\{(\lambda, v) \in \mathbb{C} \oplus V\colon\ \|v\| < 2,\ \frac{1}{2} < |\lambda| < 4\right\}. \tag{43}$$

Assume G acts trivially on $\mathbb{C}$ and $\mathbb{R}$ and take a continuous map $a : S^1 \to GL^G(V)$, where $GL^G(V)$ stands for the set of all G-equivariant linear invertible maps in V. Define a G-equivariant map $f : \overline{\mathcal{O}} \to \mathbb{R} \oplus V$ by

$$f_a(\lambda, v) = \left(|\lambda|\big(\|v\| - 1\big) + \|v\| + 1, a\left(\frac{\lambda}{|\lambda|}\right)v\right), \quad (\lambda, v) \in \overline{\mathcal{O}}. \tag{44}$$

How can one compute the twisted degree $G\text{-}\mathrm{Deg}^t(f_a, \mathcal{O})$?

Our approach to attack the above problem contains the following four ingredients:

(i) *Recurrence Formula* (see Theorem 3.41) allowing a reduction of the general problem to the computation of the corresponding S^1-degree;

(ii) *Splitting Lemma* (cf. Lemma 3.37) allowing a reduction to subrepresentations;

(iii) *Homotopy Factorization* (cf. Corollaries 3.36 and 3.38) allowing a factorization of a given map through canonical representatives of the elements of $\pi_1(GL^G(k,\mathbb{C}))$ and next deformations to the so-called $\mathbb{C}$-complementing maps being natural "complex counterparts" for the k-th basic maps (cf. Definition 3.33);

(iv) *Suspension Procedure* allowing to reduce the computation of the S^1-degree of $\mathbb{C}$-complementting maps to the one of k-th basic maps (cf. Proposition 3.34).

The last three techniques come together at the end of this subsection (see Theorem 3.39 where the S^1-degree for (44) is given). Observe that the Splitting Lemma is presented in a form much more general than is needed to establish Theorem 3.39.

$\mathbb{C}$-complementing maps and suspension procedure We start with the following

DEFINITION 3.33. Let $b:\mathbb{R}\oplus\mathcal{V}_k\to\mathcal{V}_k$ (resp. $b^-:\mathbb{R}\oplus\mathcal{V}_k\to\mathcal{V}_k$) be the k-th basic map defined by (40) (resp. the map defined by $b^-(t,v)=(1-\|v\|-it)v$, $t\in\mathbb{R}$, $v\in\mathcal{V}_k$) and let ${}^k\Omega$ be defined by (39). Assume that $\mathcal{V}_k$ is equipped with the natural complex structure and $\mathcal{O}$ is given by (43) with $V:=\mathcal{V}_k$. Suppose, finally, that $f:\mathbb{C}\oplus\mathcal{V}_k\to\mathbb{R}\oplus\mathcal{V}_k$ (resp. $f^-:\mathbb{C}\oplus\mathcal{V}_k\to\mathbb{R}\oplus\mathcal{V}_k$) is defined by $f(\lambda,v)=(|\lambda|(\|v\|-1)+\|v\|+1,\lambda\cdot v)$ (resp. $f^-(\lambda,v)=(|\lambda|(\|v\|-1)+\|v\|+1,\bar{\lambda}\cdot v)$), where $\lambda\in\mathbb{C}$, $v\in\mathcal{V}_k$. Then, the pair $(f,\mathcal{O})$ (resp. $(f^-,\mathcal{O})$) is called a $\mathbb{C}$-*complementing pair* to $(b,{}^k\Omega)$ (resp. denoted by $(b^-,{}^k\Omega)$).

It is clear that $(f,\mathcal{O})$, $(f^-,\mathcal{O})$, $(b,{}^k\Omega)$ and $(b^-,{}^k\Omega)$ are admissible pairs. The following statement (basically, its proof is a careful usage of properties (P2)–(P4)) justifies the above definition.

PROPOSITION 3.34. *Let $(f,\mathcal{O})$ (resp. $(f^-,\mathcal{O})$) be a $\mathbb{C}$-complementing pair to $(b,{}^k\Omega)$ (resp. $(b^-,{}^k\Omega)$). Then f (resp. f^-) is S^1-homotopic (by an $\mathcal{O}$-admissible homotopy) to a map $\overline{f_1}$ (resp. $\overline{f_1^-}$), which is a suspension of b (resp. b^-) on an open subset containing zeros of $\overline{f_1}$ (resp. $\overline{f_1^-}$). In particular,*

$$S^1\text{-Deg}(f,\mathcal{O})=S^1\text{-Deg}(b,{}^k\Omega)=(\mathbb{Z}_k),\tag{45}$$

$$S^1\text{-Deg}(f^-,\mathcal{O})=S^1\text{-Deg}(b^-,{}^k\Omega)=-(\mathbb{Z}_k).\tag{46}$$

Homotopy factorization: Properties of $GL^G(V)$ Consider a continuous map $\varphi:S^1\to\mathbb{C}\setminus\{0\}$. Denote by $\tilde{\varphi}$ a continuous extension of φ to the space $\mathbb{C}$. Put $B:=\{z\in\mathbb{C}\colon |z|<1\}$. Clearly, the Brouwer degree $\deg(\tilde{\varphi},B)$ depends only on the map φ. Moreover, by classical Hopf theorem (see [44]), for two continuous maps $\varphi,\psi:S^1\to\mathbb{C}\setminus\{0\}$, φ is homotopic to ψ if and only if $\deg(\tilde{\varphi},B)=\deg(\tilde{\psi},B)$.

Denote by $GL(m,\mathbb{C})$ the group of all complex invertible $m\times m$-matrices. The following fact is well-known.

PROPOSITION 3.35. (*See, for instance, [93].*)

(i) *Two continuous maps* $\Phi, \Psi : S^1 \to GL(m, \mathbb{C})$, $m \geqslant 1$, *are homotopic if and only if the maps* $\varphi := \det_{\mathbb{C}} \circ \Phi$ *and* $\psi := \det_{\mathbb{C}} \circ \Psi$ *are homotopic, i.e.*

$$\deg(\tilde{\varphi}, B) = \deg(\tilde{\psi}, B).$$

(ii) *For every map* $\Phi : S^1 \to GL(m, \mathbb{C})$, *there exists* $l \in \mathbb{Z}$ *such that* Φ *is homotopic to* Φ_l *given by*

$$\Phi_l(\gamma) := \begin{bmatrix} \gamma^l & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{bmatrix}, \quad \gamma \in S^1. \tag{47}$$

In particular, for $\varphi_l := \det_{\mathbb{C}} \circ \Phi_l$, *one has* $\deg(\tilde{\varphi}_l, B) = l$.

Combining Proposition 3.35 with Proposition 2.9 yields

COROLLARY 3.36. *Let* V *be an orthogonal* G*-representation and* V_{k_o} *an isotypical component of* V *modeled on an irreducible* G*-representation* $\mathcal{V}_{k_o}$ *of complex type. Assume* $m = \dim V_{k_o} / \dim \mathcal{V}_{k_o}$. *Then*:

(i) $GL^G(V_{k_o}) \simeq GL(m, \mathbb{C})$;

(ii) *for each* $a \in \pi_1(GL^G(V_{k_o}))$, *there exists a representative* $\varphi_a : S^1 \to GL(m, \mathbb{C})$, *such that*

$$\varphi_a(\lambda) = \begin{bmatrix} \lambda^l & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{bmatrix}, \quad \lambda \in S^1,$$

for some $l \in \mathbb{Z}$. *In particular, we have an isomorphism* $\mu_{k_o} : \pi_1(GL^G(V_{k_o})) \to \mathbb{Z}$, *where* $\mu_{k_o}(a) = l$.

Splitting lemma Combining properties (P1)–(P4) of the twisted degree with standard techniques from complex analytic function theory, one can establish

LEMMA 3.37 (Splitting Lemma). *Let* V_1 *and* V_2 *be orthogonal* G*-representations and* $V = V_1 \oplus V_2$. *Assume that the* G*-isotypical decomposition of* V *contains only components modeled on irreducible* G*-representations of complex type. Suppose that* $a_j : S^1 \to GL^G(V_j)$, $j = 1, 2$, *are two continuous maps and* $a : S^1 \to GL^G(V)$ *is given by*

$$a(\lambda) = a_1(\lambda) \oplus a_2(\lambda), \quad \lambda \in S^1.$$

Assume that $\mathcal{O}$ *and* f_a *are defined by* (43) *and* (44), *respectively. Put*

$$\mathcal{O}_j := \left\{ (\lambda, v_j) \in \mathbb{C} \oplus V_j \colon \ \|v_j\| < 2, \ \frac{1}{2} < |\lambda| < 4 \right\},$$

$$f_{a_j}(\lambda, v_j) := \left(|\lambda|\big(\|v_j\| - 1\big) + \|v_j\| + 1, a_j\left(\frac{\lambda}{|\lambda|}\right)v_j \right),$$

where $j = 1, 2$ *and* $v_j \in V_j$. *Then,*

$$G\text{-Deg}^t(f_a, \mathcal{O}) = G\text{-Deg}^t(f_{a_1}, \mathcal{O}_1) + G\text{-Deg}^t(f_{a_2}, \mathcal{O}_2). \tag{48}$$

S^1-degree formulae Here, we combine the above results to compute the S^1-degree of (44). We start with the following

COROLLARY 3.38. *Let* $V := \mathcal{V}_k$ *be the* k*-th irreducible* S^1*-representation* $(k > 0)$ *equipped with the natural complex structure,* $l \in \mathbb{Z}$ *and*

$$\tilde{f}(\lambda, v) = \left(|\lambda|\big(\|v\| - 1\big) + \|v\| + 1, \left(\frac{\lambda}{|\lambda|}\right)^l v \right), \quad (\lambda, v) \in \overline{\mathcal{O}},$$

where $\mathcal{O}$ *is given by* (43). *Then,*

$$S^1\text{-Deg}(\tilde{f}, \mathcal{O}) = l(\mathbb{Z}_k).$$

PROOF. For the sake of definiteness, assume that $l > 0$ (the case $l \leqslant 0$ can be treated using similar arguments), and consider the map

$$\tilde{f} \times \mathrm{Id} : \overline{\mathcal{O}} \times \overline{B_{l-1}} \to \mathbb{R} \oplus \mathcal{V}_k \oplus \big[\underbrace{\mathcal{V}_k \oplus \cdots \oplus \mathcal{V}_k}_{l-1}\big],$$

where $B_{l-1} = \underbrace{B(\mathcal{V}_k) \times \cdots \times B(\mathcal{V}_k)}_{l-1}$ and $B(\mathcal{V}_k)$ denotes the unit ball in $\mathcal{V}_k$. Then, by suspension property,

$$S^1\text{-Deg}(\tilde{f}, \mathcal{O}) = S^1\text{-Deg}(\tilde{f} \times \mathrm{Id}, \mathcal{O} \times B_{l-1}).$$

Obviously, $\tilde{f} \times \mathrm{Id}$ is equivariantly homotopic, by an $\mathcal{O} \times B_{l-1}$-admissible homotopy, to f_a given by (44) where $v \in V = \underbrace{\mathcal{V}_k \oplus \cdots \oplus \mathcal{V}_k}_{l}$ and $a : S^1 \to GL^{S^1}(V)$ is defined by

$$a(\gamma) = \begin{bmatrix} \gamma^l & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{bmatrix}, \quad \gamma \in S^1.$$

Using Proposition 3.35, it is easy to see that f_a is equivariantly homotopic (by an $\mathcal{O} \times B_{l-1}$-admissible homotopy) to f_b given by

$$f_b(\lambda, v) = \left(|\lambda|\|\big(\|v\| - 1\big) + \|v\| + 1, b\left(\frac{\lambda}{|\lambda|}\right)v \right),$$

with $b : S^1 \to GL^{S^1}(V)$ defined by

$$b(\gamma) = \begin{bmatrix} \gamma & 0 & \dots & 0 \\ 0 & \gamma & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \gamma \end{bmatrix}, \quad \gamma \in S^1.$$

Since $S^1\text{-Deg}(\tilde{f}, \mathcal{O}) = S^1\text{-Deg}(f_b, \mathcal{O} \times B_{l-1})$, by Splitting Lemma (cf. Lemma 3.37) and Proposition 3.34,

$$S^1\text{-Deg}(\tilde{f}, \mathcal{O}) = \underbrace{(\mathbb{Z}_k) + \cdots + (\mathbb{Z}_k)}_{l} = l(\mathbb{Z}_k).$$

□

By combining Proposition 3.35, Corollary 3.36, Splitting Lemma (cf. Lemma 3.37), and Corollary 3.38, we immediately obtain

THEOREM 3.39. *Let V be an orthogonal S^1-representation with $V^{S^1} = \{0\}$, admitting the isotypical decomposition* (42) *and equipped with the natural complex structure. Let $\mathcal{O}$* (*resp. f_a*) *be defined by* (43) (*resp.* (44)). *Then,*

$$S^1\text{-Deg}(f, \mathcal{O}) = \sum_{j=1}^{s} l_j (\mathbb{Z}_{k_j}), \tag{49}$$

where $l_j := \deg(\det_{\mathbb{C}} \circ a_j, B)$, $a_j(\lambda) := a(\lambda)|_{V_{k_j}} : V_{k_j} \to V_{k_j}$, for $j = 1, 2, \dots, s$ and $B := \{z \in \mathbb{C}\colon |z| < 1\}$.

As an immediate consequence of Theorem 3.39, one has

COROLLARY 3.40. *Let V and $\mathcal{O}$ be as in Theorem* 3.39. *Let $l_j \in \mathbb{Z}$, $j = 1, 2, \dots, s$, be given integers and assume that $\dim_{\mathbb{C}} V_{k_j} = m_j$. Define $f : \overline{\mathcal{O}} \to \mathbb{R} \oplus V$ by*

$$f(\lambda, v_1, \dots, v_n) = \big(|\lambda|\big(\|v\| - 1\big) + \|v\| + 1, \lambda^{l_1} v_1, \dots, \lambda^{l_s} v_s\big),$$

where $\lambda \in \mathbb{C} \setminus \{0\}$, $v_j \in V_{k_j}$. Then,

$$S^1\text{-Deg}(f, \mathcal{O}) = \sum_{j=1}^{n} m_j l_j (\mathbb{Z}_{k_j}). \tag{50}$$

Recurrence formula We complete this subsection with the so-called Recurrence Formula for the twisted G-equivariant degree, which, to some extent, can be counted as the Borsuk–Ulam theorem in the case of one free parameter. This formula allows a reduction of computations of G-equivariant twisted degree to the S^1-degree.

Let G, V, Ω and f be as in Proposition 3.27. Take $(H) \in \Phi_1^t(G)$ and put $f^H := f_{|\mathbb{R}\oplus V^H}$. Clearly (cf. Proposition 3.21(i)), f^H is S^1-equivariant and Ω^H-admissible, thus

$$S^1\text{-Deg}(f^H, \Omega^H) = n_{k_1}(\mathbb{Z}_{k_1}) + \cdots + n_{k_r}(\mathbb{Z}_{k_r}) \tag{51}$$

is correctly defined (cf. (38)). Put

$$\deg_k(f^H, \Omega^H) := n_k. \tag{52}$$

By combining Propositions 3.14, 3.15 and Lemma 3.17, one can prove

THEOREM 3.41 (Recurrence Formula). *Let* $G, V, \Omega \subset \mathbb{R} \oplus V$ *and* f *be as in Proposition* 3.27. *Assume, further, that*

$$G\text{-Deg}^t(f, \Omega) = \sum_{(H)\in\Phi_1^t(G,\Omega)} n_H \cdot (H) \tag{53}$$

is defined according to (35)–(37). *Then,*

$$n_H = \Big[\sum_k \deg_k(f^H, \Omega^H) - \sum_{(K)>(H)} n_K n(H,K)\big|W(K)/S^1\big|\Big] \Big/ \big|W(H)/S^1\big| \tag{54}$$

(*see* (52) (*resp.* (28)) *for the definition of* $\deg_k(f^H, \Omega^H)$ (*resp.* $n(H,K)$).

3.8. *General concept of basic maps*

The case of one free parameter The concept of the *basic maps*, which was introduced in Subsection 3.6 for S^1-equivariant maps (see (39) and (40)), can be generalized to G-equivariant maps, where $G = \Gamma \times S^1$. Following the same lines as in Subsection 3.6, we also define the counter part of a basic map, called a $\mathbb{C}$-*complementing* map.

DEFINITION 3.42.

(a) Under the notations explained in Remark and Notation 2.6, let $\mathcal{O} \subset \mathbb{R} \oplus \mathcal{V}_{j,l}$ be defined by

$$\mathcal{O} = \left\{(t, v)\colon \frac{1}{2} < \|v\| < 2,\ -1 < t < 1\right\}, \tag{55}$$

and $b : \overline{\mathcal{O}} \to \mathcal{V}_{j,l}$ be defined by

$$b(t, v) = \big(1 - \|v\| + \mathrm{i}t\big) \cdot v, \quad (t, v) \in \overline{\mathcal{O}}. \tag{56}$$

Then, the map b is called a *basic map* on $\mathcal{O}$, and the pair $(b, \mathcal{O})$ is called a *basic pair* for the irreducible G-representation $\mathcal{V}_{j,l}$.

(b) Let

$$\Omega = \left\{(\lambda, v) \in \mathbb{C} \oplus \mathcal{V}_{j,l}\colon\ \|v\| < 1,\ \frac{1}{2} < |\lambda| < 4\right\} \tag{57}$$

and $\mathfrak{f}\colon \overline{\Omega} \to \mathbb{R} \oplus \mathcal{V}_{j,l}$ be defined as

$$\mathfrak{f}(\lambda, v) = \bigl(|\lambda|\bigl(\|v\| - 1\bigr) + \|v\| + 1, \lambda \cdot v\bigr), \quad (\lambda, v) \in \overline{\Omega}, \tag{58}$$

where $\lambda \cdot v$ denotes the usual complex multiplication of v by λ. Then, the map $\mathfrak{f}$ is called a $\mathbb{C}$-*complementing map* on Ω, and the pair $(\mathfrak{f}, \Omega)$ is called a $\mathbb{C}$-*complementing pair* for the irreducible G-representation $\mathcal{V}_{j,l}$.

Obviously, both (56) and (58) are G-equivariant. Moreover, b is $\mathcal{O}$-admissible and $\mathfrak{f}$ is Ω-admissible. Therefore, $G\text{-Deg}^t(b, \mathcal{O})$ and $G\text{-Deg}^t(\mathfrak{f}, \Omega)$ are correctly defined. Although b and $\mathfrak{f}$ are rather different in nature (b seems to be the simplest one having a non-trivial twisted equivariant degree, while $\mathfrak{f}$ is motivated by the applications to the bifurcation theory, where it appears naturally), we have the following statement parallel to Proposition 3.34.

PROPOSITION 3.43. *Let $\mathcal{U}_j$ be a complex irreducible Γ-representation and $\mathcal{V}_{j,l} := {}^l\mathcal{U}_j$ the associated irreducible representation of $G = \Gamma \times S^1$ (cf. Remark and Notation* 2.6). *Then,*

$$G\text{-Deg}^t(b, \mathcal{O}) = G\text{-Deg}^t(\mathfrak{f}, \Omega), \tag{59}$$

where $\mathcal{O}$, b, Ω and $\mathfrak{f}$ are given by (55)–(57) *and* (58), *respectively.*

For the sequel, it is convenient to introduce

DEFINITION 3.44. Let $(b, \mathcal{O})$ be a basic pair for the irreducible G-representation $\mathcal{V}_{j,l}$. Put

$$\deg_{\mathcal{V}_{j,l}} := G\text{-Deg}^t(b, \mathcal{O}), \tag{60}$$

and call $\deg_{\mathcal{V}_{j,l}}$ the *basic degree* for $\mathcal{V}_{j,l}$.

Using the same ideas as in the proof of Corollary 3.38 in compliance with Corollary 3.36, one can easily establish a formula allowing in certain important cases a reduction to basic degrees.

PROPOSITION 3.45. *Under the notations and assumptions of Problem* 3.32 *suppose, in addition, that*:

(i) *V has a single G-isotypical component modeled on an irreducible G-representation $\mathcal{V}_{j,l}$ and $m = \dim V / \dim \mathcal{V}_{j,l}$;*

(ii) *the map a from formula* (44)*, identified with a map $S^1 \to GL(m, \mathbb{C})$* (*cf. Corollary* 3.36(ii)) *admits a representation* $\operatorname{diag}\{(\lambda^k, 1, 1, \dots, 1\}$.

Then,

$$G\text{-Deg}^t(f_a, \mathcal{O}) = k \cdot \deg_{\mathcal{V}_{j,l}}. \tag{61}$$

Observe that basic maps play an essential role in practical computations of the twisted degree. A typical degree-theoretical approach to a concrete problem is usually devised on the so-called *linearization techniques*. These techniques are based on local or global linear approximations, which can be considered as a way of transforming the original map to the one for which the degree can be easily evaluated. In the case of the equivariant degree with one free parameter, the linearization techniques are also used. However, due to the nature of the equivariant degree, it is inappropriate to expect the same type of computations for all kinds of groups. That means, in order to establish a standard method for the computations of the (twisted) equivariant degree, one needs to identify the key elements in this process. It turns out that the *basic degrees* are essential for the computations of the twisted degrees of arbitrary maps. By providing for a considered group $\Gamma \times S^1$ the tables of basic degrees, one is able to remove essential technical obstructions from the computation process of the twisted degree.

It should be pointed out that the computational formulae presented in Subsection 3.7 are enough to completely evaluate $\deg_{\mathcal{V}_{j,l}}$. Indeed, consider the representation $\mathcal{V}_{j,1}$ (the case of arbitrary $l > 1$ can be analyzed similarly). The Recurrence Formula (see Theorem 3.41) reduces the computations of $\deg_{\mathcal{V}_{j,1}}$ to $\deg_1(f^H, \Omega^H)$ and numbers $n(H, K)$, where $(H), (K) \in \Phi_1^t(G)$. Next, by Corollary 3.40, one obtains

$$\deg_1(f^H, \Omega^H) = \frac{1}{2} \dim \mathcal{V}_{j,1}^H. \tag{62}$$

Thus, to compute $\deg_{\mathcal{V}_{j,1}}$ one needs to know: (i) twisted orbit type lattice in $\mathcal{V}_{j,1}$, (ii) dimensions of H-fixed-point subspaces in $\mathcal{V}_{j,1}$ ($(H) \in \Phi_1^t(G)$), and (iii) numbers $n(H, K)$. Therefore, the computations of basic degrees can be completely computerized.

The case without free parameter Similarly to the situation of one free parameter, one could look for an appropriate concept of *basic maps* in the case without free parameters (cf. Remark 3.28). However, in the latter case, this concept turns out to be almost trivial. To be more specific, consider an irreducible orthogonal representation $\mathcal{V}_i$ of the compact Lie group Γ, and let $\mathcal{D}$ be the unit ball in $\mathcal{V}_i$. It is clear that every linear Γ-equivariant isomorphism A from $\mathcal{V}_i$ onto $\mathcal{V}_i$ is a $\mathcal{D}$-admissible Γ-equivariant map. Therefore, we can consider this type of Γ-equivariant maps as the most elementary, for which the equivariant degree $\Gamma\text{-Deg}(A, \mathcal{D})$ is defined. On the other hand, the representation $\mathcal{V}_i$ can be of one of three types: real, complex or quaternionic (cf. Proposition 2.9(ii)). It is clear that in the case $\mathcal{V}_i$ is of complex or quaternionic type, the operator A can be connected by a path in $GL^\Gamma(\mathcal{V}_i) := \{B \in L^G(\mathcal{V}_i)\colon\ B \text{ is an isomorphism}\}$ with the identity operator Id. Thus,

Γ-Deg$(A,\mathcal{D})=(\Gamma)$, which can be considered as a trivial case. In the case the representation $\mathcal{V}_i$ is of real type, the group $GL^{\Gamma}(\mathcal{V}_i)$ has two connected components, so if A does not belong to the same connected component as Id, it is homotopic to $-\,$Id, and consequently,

$$\Gamma\text{-Deg}(A,\mathcal{D})=\Gamma\text{-Deg}(-\operatorname{Id},\mathcal{D}).$$

Therefore, we call the map $-\operatorname{Id}:\mathcal{V}_i\to\mathcal{V}_i$ a *basic map* for the irreducible representation $\mathcal{V}_i$ (see [93] for more information about this type of basic maps) and put

$$\deg_{\mathcal{V}_i}:=\Gamma\text{-Deg}(-\operatorname{Id},\mathcal{D}). \tag{63}$$

It turns out that $\deg_{\mathcal{V}_i}$ can be completely evaluated using a recurrence formula similar to (53)–(54). More precisely, consider the set $\Phi_0(\Gamma,\mathcal{V}_i)$ of all the orbit types (L_k) in $\mathcal{V}_i$ such that $(L_k)\in\Phi_0(\Gamma)$. Then (see [93]),

$$\deg_{\mathcal{V}_i}=\sum_k n_{L_k}\cdot(L_k), \tag{64}$$

where

$$n_{L_{k_o}}=\frac{(-1)^{n_{k_o}}-\sum_{k=1}^{k_o-1}n(L_{k_o},L_k)\cdot n_{L_k}\cdot|W(L_k)|}{|W(L_{k_o})|} \tag{65}$$

and $n_k=\dim\mathcal{V}_i^{L_k}$.

3.9. *Multiplicativity property*

In this subsection, we connect the multiplication structures on $A(\Gamma)$ (resp. $A_1^t(G)$) to the Γ-equivariant degree (resp. twisted degree) of Γ-equivariant maps without free parameter (resp. G-equivariant maps with one free parameter). The well-known multiplicativity property of the classical Brouwer degree, which asserts that the degree of a direct product of maps is equal to the product of their degrees (in the ring $\mathbb{Z}$), can be thought of as the prototype of the theorems following below (their proofs use a regular normality argument combined with the definitions of the multiplications in $A(\Gamma)$ (resp. $A_1^t(G)$) and a careful count of orbits of zeros in the product maps).

THEOREM 3.46. *Let Γ be a compact Lie group, U and W two orthogonal Γ-representations, $\Omega_1\subset U$, $\Omega_2\subset W$ two open bounded Γ-invariant sets. Assume that $s:V\to V$ (resp. $g:W\to W$) is an Ω_1-admissible (resp. Ω_2-admissible) equivariant map. Then,*

$$\Gamma\text{-Deg}(s\times g,\Omega_1\times\Omega_2)=\Gamma\text{-Deg}(s,\Omega_1)\cdot\Gamma\text{-Deg}(g,\Omega_2), \tag{66}$$

where ‘$\cdot$’ stands for the multiplication in the Burnside ring $A(\Gamma)$ (see also Remark 3.28).

REMARK 3.47. Clearly, under the notations of Theorem 3.46, one immediately obtains the multiplicativity property for the usual Brouwer degree by putting $\Gamma = \{e\}$.

THEOREM 3.48 (Multiplicativity property). *Let* Γ *be a compact Lie group,* $G = \Gamma \times S^1$, V (*resp.* W) *an orthogonal* G*-representation* (*resp.* Γ*-representation*), $\Omega_1 \subset \mathbb{R} \oplus V$ (*resp.* $\Omega_2 \subset W$) *an invariant open bounded set and* $f_1 : \mathbb{R} \oplus V \to V$ (*resp.* $f_2 : W \to W$) *an* Ω_1*-admissible* (*resp.* Ω_2*-admissible*) *equivariant map. Then,*

$$G\text{-Deg}^t(f_1 \times f_2, \Omega_1 \times \Omega_2) = \Gamma\text{-Deg}(f_2, \Omega_2) \cdot G\text{-Deg}^t(f_1, \Omega_1),$$

where the multiplication is taken in the $A(\Gamma)$*-module* $A_1^t(G)$ (*see also Remark* 3.28).

REMARK 3.49. Obviously, in the case $\Gamma = \{e\}$, one has to take for Γ-Deg(f_2, Ω_2) the usual Brouwer degree and for "$\cdot$" the usual multiplication by an integer.

3.10. *Infinite dimensional twisted degree*

In order to apply the twisted degree theory developed above to symmetric Hopf bifurcation problems, one should extend it to reasonable classes of equivariant vector fields on *infinite dimensional* Banach G-representations. To this end, it is necessary to adopt the standard infinite dimensional techniques in the equivariant setting. Below, we briefly discuss the corresponding framework for two classes of vector fields relevant to the applications we are dealing with in this paper: (i) compact fields and (ii) condensing fields. Observe, however, that extensions to many other important classes can be easily done as well.

Throughout this subsection, W is a real isometric Banach G-representation ($G = \Gamma \times S^1$), $E := \mathbb{R} \oplus W$ is equipped with the norm $\|(\lambda, v)\| = \max\{|\lambda|, \|v\|\}$ (G acts trivially on $\mathbb{R}$) and $\pi : E \to W$ stands for the natural projection on W. Given a G-invariant subset $M \subset E$ and a G-equivariant map $F : M \to W$, define $f : M \to W$ by

$$f := \pi - F, \tag{67}$$

and call f a *G-equivariant field* on M.

Leray–Schauder twisted degree Recall the following

DEFINITION 3.50. Let $X \subset E$ be a bounded subset. Then, a continuous map $F : X \to W$ is called *compact*, if $\overline{F(X)}$ is compact in W.

THEOREM 3.51 (Equivariant Schauder approximation theorem). *Let* $X \subset E$ *be a* G*-invariant bounded subset and* $F : X \to W$ *a* G*-equivariant compact map. Then, for every* $\varepsilon > 0$, *there exists a* G*-equivariant finite-dimensional map* $F_\varepsilon : X \to W$ (*i.e. the image* $F_\varepsilon(X)$ *is contained in a finite-dimensional subrepresentation of* W) *such that*

$$\|F_\varepsilon(x) - F(x)\| < \varepsilon \quad \text{for all } x \in X. \tag{68}$$

PROOF. Take W_∞ defined by (17)–(19). By (20), there exists a finite set $N = \{v_1, \ldots, v_n\} \subset W_\infty$ such that $F(X) \subset N_\varepsilon := N + B_\varepsilon(0)$, where $B_\varepsilon(0) = \{v \in W\colon \|v\| < \varepsilon\}$. Define the functions $\nu_k : N_\varepsilon \to \mathbb{R}$, $k = 1, \ldots, n$, by $\nu_k(v) := \max\{0, \varepsilon - \|v - v_k\|\colon k = 1, 2, \ldots, n\}$, $v \in N_\varepsilon$, and put $P_\varepsilon(v) := \frac{1}{\sum_{k=1}^n \nu_k(v)} \sum_{k=1}^n \nu_k(v) v_k \in \operatorname{conv}\{v_1, \ldots, v_n\}$, $v \in N_\varepsilon$, where "conv" stands for the convex hull.

Next, define the map $\widetilde{F}_\varepsilon : X \to W$ by $\widetilde{F}_\varepsilon(x) := P_\varepsilon(F(x))$ for $x \in X$. Clearly, $\widetilde{F}_\varepsilon$ satisfies (68) and $\widetilde{F}_\varepsilon(X) \subset \operatorname{span}\{G(v_1), \ldots, G(v_n)\} =: A$. By Proposition 2.12, A is G-invariant and finite-dimensional.

To complete the proof, put $F_\varepsilon(x) := \int_G g \widetilde{F}_\varepsilon(g^{-1}x)\, \mathrm{d}\mu(g)$, $x \in X$ (here μ denotes the Haar measure on G). ☐

The construction of the Leray–Schauder equivariant degree is standard.

DEFINITION 3.52. Assume that $\Omega \subset E$ is an open bounded G-invariant subset, $F : \overline{\Omega} \to W$ is a compact equivariant map.

(a) A G-equivariant field f defined by (67) is called *compact*. Such a field f is called Ω-*admissible* if $f(x) \neq 0$ for all $x \in \partial\Omega$.

(b) Two G-equivariant Ω-admissible compact fields $f_0 = \pi - F_0$ and $f_1 = \pi - F_1$ are said to be *G-equivariantly homotopic*, if there exists a G-equivariant compact map $H : [0, 1] \times \overline{\Omega} \to W$ with $h := \pi - H$ satisfying the following conditions:
  (i) $h(0, \cdot) = f_0$, $h(1, \cdot) = f_1$;
  (ii) for each $\lambda \in [0, 1]$, $h(\lambda, \cdot)$ is Ω-admissible.

  The map h will be referred to as a *G-equivariant homotopy of compact fields* joining f_0 and f_1.

In order to define the twisted degree $G\text{-}\mathrm{Deg}^t(f, \Omega)$ of an Ω-admissible G-equivariant compact field f, take an equivariant finite-dimensional map $F_\varepsilon : \overline{\Omega} \to W$ such that $F_\varepsilon(\overline{\Omega}) \subset W_*$, $\dim W_* < \infty$ and

$$\big\| F(x) - F_\varepsilon(x) \big\| < \inf\big\{ \big\| f(y) \big\|\colon y \in \partial\Omega \big\},$$

and next, define the ε-approximation f_ε of f as $f_\varepsilon(\lambda, v) = v - F_\varepsilon(\lambda, v)$, $(\lambda, v) \in \overline{\Omega}$ (cf. Theorem 3.51). Then, put

$$G\text{-}\mathrm{Deg}^t(f, \Omega) \overset{\text{def}}{=} G\text{-}\mathrm{Deg}^t(f_\varepsilon|_{\overline{\Omega}_*}, \Omega_*) \in A_1^t(G), \tag{69}$$

where $\Omega_* := \Omega \cap (\mathbb{R} \oplus W_*)$, and call $G\text{-}\mathrm{Deg}^t(f, \Omega)$ the *Leray–Schauder twisted degree*.

By applying the standard arguments, one can verify that the definition, given by formula (69), neither depends on a choice of the equivariant approximation f_ε, nor on an invariant finite-dimensional subspace W_* (see [93] for more details).

Using Definition 3.52 and following the standard lines (cf. [81] and [93]), one can formulate and prove an analogue of Proposition 3.27 for compact fields and homotopies.

Nussbaum–Sadovskii twisted degree Denote by $\mathcal{M}$ the class of all bounded subsets of E.

DEFINITION 3.53. A function $\mu : \mathcal{M} \to [0, \infty)$ is called a *measure of noncompactness* on E if for all $A, B \in \mathcal{M}$, the following conditions are satisfied:

(a) $\mu(A) = 0 \Leftrightarrow \bar{A}$ is compact;
(b) $\mu(A) = \mu(\bar{A})$;
(c) $\mu(\mathrm{conv}(A)) = \mu(A)$;
(d) $\mu(A \cup B) = \max\{\mu(A), \mu(B)\}$;
(e) $\mu(rA) = |r| \cdot \mu(A)$, $r \in \mathbb{R}$;
(f) $\mu(A + B) \leqslant \mu(A) + \mu(B)$.

We refer to [1] and [93], where many important examples of measures of noncompactness are considered as well as their properties are studied.

DEFINITION 3.54. Let μ be a measure of noncompactness defined on $\mathcal{M}$. Take $X \subset E$ and $Y \subset W$. Consider a continuous map $F : X \to Y$ taking bounded subsets of X to bounded subsets of Y. We say that F is:

(i) a *μ-Lipschitzian map* with a constant $L \geqslant 0$, if $\mu(F(A)) \leqslant L\mu(A)$ for all bounded subsets A of X;
(ii) a *completely continuous map*, if it is μ-Lipschitzian with a constant $L = 0$;
(iii) a *condensing map*, if it is μ-Lipschitzian with a constant $L = 1$ and $\mu(F(A)) < \mu(A)$ for every bounded subset $A \subset X$ such that $\mu(A) > 0$.

REMARK 3.55.

(i) Clearly, any compact map is also completely continuous. The opposite statement is true under the assumption that the domain of the map is bounded. Also, any completely continuous map is, of course, condensing with respect to any measure of noncompactness.
(ii) Obviously, if $F : E \to W$ is a contraction map (i.e. there exists $0 \leqslant q < 1$ such that $\|F(x) - F(y)\| \leqslant q\|x - y\|$ *for all* $x, y \in E$), then F is condensing with respect to any measure of noncompactness on $\mathcal{M}$ (the applications to neutral FDEs we will be dealing with appeal exactly to this situation).

The idea of extending the equivariant Leray–Schauder degree to the class of equivariant condensing fields, is based on the same standard construction that is used in order to make such an extension in the non-equivariant case (see for example [1] and [93], Chapter 4). For the sake of completeness of our presentation, we discuss shortly some of the main steps of this construction.

DEFINITION 3.56. Let $\Omega \subset E$ be an open bounded G-invariant subset and $F : \overline{\Omega} \to W$ a condensing equivariant map with respect to some (fixed) measure of noncompactness μ on E.

(a) The map f defined by (67) is called a *condensing field*.
(b) Two G-equivariant Ω-admissible condensing fields $f_0 = \pi - F_0$ and $f_1 = \pi - F_1$ are called *G-equivariantly homotopic*, if there exists a G-equivariant condensing map $H : [0, 1] \times \overline{\Omega} \to W$ with $h := \pi - H$ satisfying the following conditions:

(i) $h(0,\cdot)=f_0$, $h(1,\cdot)=f_1$;
(ii) for each $\lambda\in[0,1]$, $h(\lambda,\cdot)$ is Ω-admissible.

The map h will be referred to as a *G-equivariant homotopy of condensing fields* joining f_0 and f_1. The map H is called a *condensing G-equivariant homotopy* between F_0 and F_1.

The following notion (see [1] for the non-equivariant setting) plays the central role in our considerations.

DEFINITION 3.57. Let $M\subset E$ be an invariant subset and $F:M\to W$ an equivariant map. A subset $Q\subset W$ is called *G-fundamental* for F, if it satisfies the following conditions:
(a) Q is non-empty, compact, convex and G-invariant;
(b) $F(M\cap Q)\subset Q$;
(c) if $x_o\in M\setminus Q$, then $x_o\notin \operatorname{conv}(F(x_o)\cup Q)$.
Observe that a G-fundamental set Q for F contains all the fixed points of F.

Similarly, one can define a notion of a G-fundamental set for a G-equivariant deformation $H:[0,1]\times M\to W$, namely, this set should be G-fundamental for each $H(\lambda,\cdot)$.

REMARK 3.58. Obviously, if $X\subset W$ is a (non-empty) compact G-invariant subset, then so is $\overline{\operatorname{conv}(X)}$. Therefore, for any G-equivariant compact map $F:M\to W$, where $M\subset E$, the set $\overline{\operatorname{conv}(F(M))}$ is G-fundamental.

It turns out (cf. [1])

LEMMA 3.59. *Let $\Omega\subset E$ be an open bounded G-invariant subset, $H:[0,1]\times\overline{\Omega}\to W$ a G-equivariant Ω-admissible condensing homotopy, $K\subset W$ an arbitrary G-invariant compact subset. Then, there exists a G-fundamental set for H containing K.*

Assume that $\Omega\subset E$ is an open bounded G-invariant subset, $\pi-F:\overline{\Omega}\to W$ a G-equivariant condensing Ω-admissible field. Let $Q\subset W$ be a G-fundamental set for F provided by Lemma 3.59. By the equivariant Dugundji theorem (see Proposition 3.9), there exists a G-equivariant extension $\widetilde{F}:E\to Q$ of the map $F|_{\overline{\Omega}\cap Q}$. Put $\overline{F}:=\widetilde{F}|_{\overline{\Omega}}$. Take the compact G-equivariant field $\pi-\overline{F}$ and put

$$G\text{-}\mathrm{Deg}^t(\pi-F,\Omega):=G\text{-}\mathrm{Deg}^t(\pi-\overline{F},\Omega). \tag{70}$$

We call $G\text{-}\mathrm{Deg}^t(\pi-F,\Omega)$ the *Nussbaum–Sadovskii equivariant degree*. Using Lemma 3.59, it is easy to show that the definition given by formula (70), neither depends on a choice of a G-fundamental set, nor on an equivariant extension $\overline{F}$ (see [1,93] for more details).

Using Definition 3.56 and following the standard lines (cf. [93] and [1]), one can formulate and prove an analogue of Theorem 3.27 for condensing maps.

3.11. *Bibliographical remarks*

Equivariant extensions via fundamental domains is one of the crucial ideas underlying our approach to the equivariant degree. In the context relevant to our discussion, a simplicial fundamental domain for an action of a cyclic group of prime order was used (probably, for the first time) in [47]. The case of an arbitrary cyclic group action on a sphere was considered by M. Krasnosel'skii [88] (see also the paper of P. Zabreiko [149], where a slightly more general case was considered). The case of an arbitrary finite group action on a subset of $\mathbb{R}^n$ was studied by Z. Balanov and S. Brodsky in [9]. In full generality, Theorems 3.2 and 3.4 were proved by Z. Balanov and A. Kushkuley in [20,21,98,99]. The concept of regular fundamental domain (as well as the proof of Theorem 3.7) was suggested in [14] (see also [19]). The detailed study of the case of linear actions of Abelian groups can be found in [80,81]. For the equivariant extension problem in a more general setting, we refer to [3,5,7].

The concept of normal/regular normal approximations (being, together with fundamental domains, another important ingredient of our approach to studying (twisted) equivariant degree) was discussed, on the one hand, by K. Gęba, W. Krawcewicz and J. Wu in [60], and on the other hand, by A. Kushkuley and Z. Balanov in [99] (cf. [96]). For other "equivariant general position" results (including those for different actions on the domain and image) closed in spirit to regular normal approximations, we refer to [99] (cf. [115,150]) and [81].

The numbers $n(L, H)$ were defined by E. Ihrig and M. Golubitsky in [74] (see also [99]). Proposition 3.15 and Lemma 3.17 were suggested in [14]. For a detailed discussion on the concept of Burnside ring (as well as for computations of several multiplication tables), we refer to [43] and [93]. Twisted subgroups of $\Gamma \times S^1$ for certain groups Γ of practical meaning, were studied in [10,11,15,17,18,14,67,65,66,91,92,145] (some additional information (including the numbers $n(L, H)$), can be found in [27,29,32,67,99]). The notion of bi-orientability was introduced by G. Peschke in [126] (see also [60]). Some important multiplication tables for $A_1^t(G)$ can be found in [10,18,92]. In fact, the $A(\Gamma)$-module structure on $A_1^t(\Gamma \times S^1)$ coincides with the appropriate restrictions of the multiplication in the Euler ring $U(\Gamma \times S^1)$ (cf. [43,59,134]), where $A(\Gamma)$ is identified with $\mathbb{Z}[\Phi(\Gamma \times S^1)] \subset U(\Gamma \times S^1)$. In the case Γ is a finite group, we have $U(\Gamma \times S^1) \simeq A(\Gamma) \oplus A_1^t(\Gamma \times S^1)$ (cf. [43]).

The concept of twisted degree was developed in [11,14,19]. Among the important "predecessors" of (twisted) S^1-equivariant degree, one should mention the rational-valued homotopy invariants introduced and studied in [57,39,40,42,41]. Actually, the approach suggested in Subsection 3.4 to construct the twisted degree, can be easily extended to a more general setting: G is an arbitrary compact Lie group (not necessarily of the form $G = \Gamma \times S^1$) and $f : \mathbb{R}^n \oplus V \to V$ is an equivariant map with $n \geqslant 1$ free parameters. In this case, the corresponding invariant (known as the *primary equivariant degree*) takes its values in the $\mathbb{Z}$-module $\mathbb{Z}[\Phi_n^+(G)]$, where $\Phi_n^+(G)$ consists of all "primary" conjugacy classes (H), i.e. $\dim W(H) = n$ and $W(H)$ is bi-orientable. It was considered by K. Gęba, W. Krawcewicz and J. Wu in [60] (following the differential topology framework), G. Peschke in [126] (using the algebraic topology ideas) and W. Krawcewicz and H. Xia in [96] (using an analytical approach). The axiomatic approach to the primary degree based on the use of (regular) fundamental domains was suggested by Z. Balanov,

W. Krawcewicz and H. Ruan in [14] (see also [19]). In turn, the primary equivariant degree is a part of the construction of equivariant degree defined by J. Ize, I. Massabó and A. Vignoli in [78] which is an equivariant homotopy class of a certain auxiliary equivariant map of G-representation spheres (a detailed exposition of this concept for *Abelian* group representations (including many non-trivial and elegant examples) can be found in [81]). In particular, this degree (as a complete equivariant homotopy invariant) takes into account the so-called “secondary” orbit types, i.e. those with $\dim W(H) < n$. Observe, however, that (i) the primary degree was defined in [60] (see also [45,46] for $G = S^1$) independently of the work [78] , and (ii) the general construction of the equivariant degree given in [78] (see also [81]), being of great theoretical importance, does not give practical hints for its computation.

The importance of S^1-basic and $\mathbb{C}$-complementing maps was indicated in [14] (see also [49,93,18]). The Splitting Lemma was proved in [14] based on ideas from [91]. The computational formulae for the S^1-degree were established in [14] (see also [46] and [93]). The Recurrence Formula (in a slightly different version) was suggested in [91] (see also [14] and [19]).

Twisted degrees of basic maps (being another important ingredient of our approach), for various irreducible representations, were considered in [10,11,18,14,91,92], where the importance of the numbers $n(L, H)$ for the computations of the basic degrees was first indicated. The multiplicativity property of the equivariant degree, which is crucial from the applications viewpoint, was studied in [17,18,91] (see also [81] for the Abelian group actions). The case without free parameter was considered in [93,141]. Finally, a systematic exposition of the equivariant degree theory for many important classes of non-Abelian group actions can be found in [19].

4. Hopf bifurcation problem for ODEs without symmetries

In this section, we start the (twisted) equivariant degree treatment of the Hopf bifurcation phenomena in (symmetric) dynamical systems. To clarify the main ingredients of our approach, we begin with the simplest situation – a parameterized by $\alpha \in \mathbb{R}$ system of ODEs $\dot{x} = f(\alpha, x)$, $x \in \mathbb{R}^N$, *without* spatial symmetries. It turns out that it is possible:

(i) to reformulate the original problem as the S^1-fixed point problem for a compact map $\mathcal{F} : \Omega \subset \mathbb{R} \oplus W \to W$, where W is an appropriate space of periodic $\mathbb{R}^N$-valued functions with the S^1-action induced by the shift of time variable;

(ii) to associate to the compact field $\mathfrak{F} := \pi - \mathcal{F}$ the S^1-degree whose nontriviality indicates the occurrence of a Hopf bifurcation (here, $\pi : \mathbb{R} \oplus W \to W$ is the natural projection).

In the next section, assuming the system to satisfy some Γ-symmetry conditions, we associate to $\mathfrak{F}$ the $\Gamma \times S^1$-equivariant twisted degree allowing to classify the bifurcating solutions according to their symmetries. The main advantage of this method rests on the fact that it can be equivalently applied (with certain cosmetic modifications) to other classes of equations (for instance, functional differential equations, neutral functional differential equations or partial functional differential equations).

4.1. *Statement of the problem*

Put $V := \mathbb{R}^N$. We begin with the following system of ODEs:

$$\begin{cases} \dot{x} = f(\alpha, x), & x \in V,\ \alpha \in \mathbb{R}, \\ x(0) = x(p), & \text{for a certain } p > 0, \end{cases} \tag{71}$$

where the function $f : \mathbb{R} \times V \to V$ is of class C^1 and satisfies the property

$$f(\alpha, 0) = 0 \quad \text{for all } \alpha \in \mathbb{R}. \tag{72}$$

The stationary point, at which we are analyzing the occurrence of small amplitude periodic solutions for the system (71), is (by the assumption (72)) the origin $0 \in V$. We say that for $\alpha = \alpha_o$, the system (71) has a *Hopf bifurcation* occurring at $(\alpha_o, 0)$ corresponding to the "limit period" $\frac{2\pi}{\beta_o}$, if there exists a family of p_s-periodic non-constant solutions $\{(\alpha_s, x_s(t))\}_{s\in\Lambda}$ (for a proper index set Λ) of (71) satisfying the conditions:

(1) The set $K := \bigcup_{s\in\Lambda}\{(\alpha_s, x_s(t)) \colon t \in \mathbb{R}\}$ contains a compact connected (infinite) set C such that $(\alpha_o, 0) \in C$,

(2) $\forall \varepsilon > 0$, $\exists\, \delta > 0$ such that

$$\forall \big(\alpha_s, x_s(t)\big) \in C \quad \sup_t \big\| x_s(t) \big\| < \delta \Rightarrow \|\alpha_o - \alpha_s\| < \varepsilon \text{ and } \left\| p_s - \frac{2\pi}{\beta_o} \right\| < \varepsilon.$$

With the system (71), associate the linearized at $x = x_o$ system

$$\dot{x} = D_x f(\alpha, x_o)x, \quad x \in V. \tag{73}$$

Taking the complexification of (73) and substituting the function $x(t) = \mathrm{e}^{\lambda t} \cdot v$ with $\lambda \in \mathbb{C}$ and $v \in V$, leads to the following *characteristic operator*

$$\Delta_{(\alpha, x_o)}(\lambda) := \lambda \,\mathrm{Id} - D_x f(\alpha, x_o) : V^c \to V^c, \tag{74}$$

where $V^c = \mathbb{C}^N$ denotes the complexification of V, $D_x f(\alpha, x_o)(z \otimes x) = z \otimes D_x f(\alpha, x_o)x$ for $z \otimes x \in V^c$, and the *characteristic equation*

$$\det\nolimits_{\mathbb{C}}\big[\Delta_{(\alpha, x_o)}(\lambda)\big] = 0, \quad \lambda \in \mathbb{C}. \tag{75}$$

A solution to (75) is called a *characteristic root* at the stationary point (α, x_o). It is obvious that the Hopf bifurcation occurs for the linearized system (73) with $\alpha = \alpha_o$ if and only if the characteristic equation (75) (for $\alpha = \alpha_o$) has a (non-zero) purely imaginary root $\lambda = \mathrm{i}\beta_o$. It will turn out that the appearance of a purely imaginary *characteristic root* can provide appropriate information to predict the occurrence of Hopf bifurcation for the non-linear system (71). In what follows, put $\Delta_\alpha(\cdot) := \Delta_{(\alpha,0)}(\cdot)$.

4.2. S^1-equivariant reformulation of the problem

Normalization of the period Introduce the unknown period p as an additional parameter to the considered system (71) of ODEs. For this purpose, substitute $u(t) := x(\frac{p}{2\pi}t)$, which leads to

$$\begin{cases} \dot{u} = \frac{p}{2\pi} f(\alpha, u), & u \in V, \\ u(0) = u(2\pi), \end{cases} \tag{76}$$

where the unknown function $u(t)$ is considered to be of the fixed 2π-period. Next, reparametrize the system (76) by introducing $\beta := \frac{2\pi}{p}$, i.e. we obtain

$$\begin{cases} \dot{u} = \frac{1}{\beta} f(\alpha, u), & u \in V, \\ u(0) = u(2\pi). \end{cases} \tag{77}$$

Setting in functional spaces and S^1-isotypical decomposition The system (77) can be reformulated as an equation in the appropriate functional spaces. Denote by $W := H^1(S^1; V)$ the first Sobolev space of V-valued functions defined on S^1, which can be identified with the corresponding space of 2π-periodic V-valued functions via the identification $S^1 \simeq \mathbb{R}/2\pi\mathbb{Z}$. Formula

$$(\zeta u)(t) := u(t + \tau) \quad (t \in \mathbb{R},\ u \in W,\ \zeta = e^{i\tau} \in S^1) \tag{78}$$

determines on W the structure of isometric Hilbert S^1-representation with respect to the standard inner product in W given by

$$\langle u, v \rangle_{H_1} := \int_0^{2\pi} \big(u(t) \bullet v(t) + u'(t) \bullet v'(t)\big)\, dt.$$

Identify the subspace of W consisting of all constant functions with V (it can be thought of as the "0-mode" of the isotypical decomposition of W). To describe other S^1-isotypical components W_l, $l = 1, 2, 3, \dots$, of the space W, observe that each component W_l is generated (as a linear space) by the functions $u(t) = \cos lt \cdot a_l + \sin lt \cdot b_l$, for $t \in [0, 2\pi]$, $a_l, b_l \in V$. Consequently, the function $u(t)$ can be viewed as

$$u(t) = e^{ilt} \cdot (x_l + iy_l), \quad x_l, y_l \in V. \tag{79}$$

Using (79), we can describe the action of $e^{i\tau} \in S^1$ on $u(t)$ as the 'complex multiplication' by $e^{il\tau}$. Moreover, each of the subspaces W_l, equipped with this S^1-action, is S^1-isomorphic to the complexification V^c of V, considered with the S^1-action defined by the l-folding, i.e. $W_l \simeq {}^lV^c$ (cf. Subsection 3.6 and Remark and Notation 2.6). Also, we can write the elements $u(t) \in W_l$ as $u(t) = \mathrm{e}^{\mathrm{i}lt} \cdot z$, $z \in \mathbb{C}^N$. Therefore, we have the following S^1-isotypical decomposition of W:

$$W = \overline{V \oplus \bigoplus_{l=1}^{\infty} W_l}. \tag{80}$$

S^1-equivariant fixed-point problem Define the following operators:

$$L : W \to L^2(S^1; V), \quad L(u) = \dot{u}, \tag{81}$$

$$j : W \to C(S^1; V), \quad j(u) = \tilde{u}, \tag{82}$$

where $u \in W$ and $C(S^1; V)$ denotes the space of 2π-periodic, V-valued continuous functions on $\mathbb{R}$ equipped with the usual sup-norm and $\tilde{u} = u$ a.e. (cf. [137]). For a function $u(t) = \mathrm{e}^{\mathrm{i}lt} \cdot z \in W_l$, we have $L(u) = \mathrm{i}lu$, i.e. $L|_{W_l} = \mathrm{i}l \, \mathrm{Id}|_{W_l}$. Put $\mathbb{R}^2_+ := \mathbb{R} \times \mathbb{R}_+$, $\mathbb{R}_+ := \{r \in \mathbb{R}\colon r > 0\}$, and let $\pi\colon \mathbb{R}^2 \oplus W \to W$ be the natural projection. Denote by N_f the Nemytsky operator associated with the function f, i.e. for every $\alpha \in \mathbb{R}$, put

$$\big(N_f(\alpha, v)\big)(t) := f\big(\alpha, v(t)\big), \quad v \in C(S^1; V). \tag{83}$$

Notice that the system (71) is equivalent to the following operator equation

$$Lu = \frac{1}{\beta} N_f\big(\alpha, j(u)\big), \quad (\alpha, \beta) \in \mathbb{R}^2_+, \ u \in W. \tag{84}$$

Equation (84) can be transformed to an S^1-equivariant fixed-point problem in $\mathbb{R}^2 \oplus W$. Define the operator $K : W \to L^2(S^1; V)$ by

$$K(u) := \frac{1}{2\pi} \int_0^{2\pi} u(t) \, \mathrm{d}t, \quad u \in W, \tag{85}$$

which is simply a projection on the subspace V of constant functions (cf. Remark and Notation 2.17). Then, it can be easily verified that the operator $L + K : W \to L^2(S^1; V)$ is an isomorphism. Put

$$\begin{aligned} \mathcal{F}(\alpha, \beta, u) &:= (L + K)^{-1} \left[\frac{1}{\beta} N_f\big(\alpha, j(u)\big) + K(u) \right], \\ \mathfrak{F}(\alpha, \beta, u) &:= u - \mathcal{F}(\alpha, \beta, u). \end{aligned} \tag{86}$$

In this way, the following equation is equivalent to (84):

$$\mathfrak{F}(\alpha, \beta, u) = 0, \tag{87}$$

where $(\alpha, \beta) \in \mathbb{R}^2_+$, $u \in W$ (cf. Subsection 3.6 and Remark and Notation 2.6).

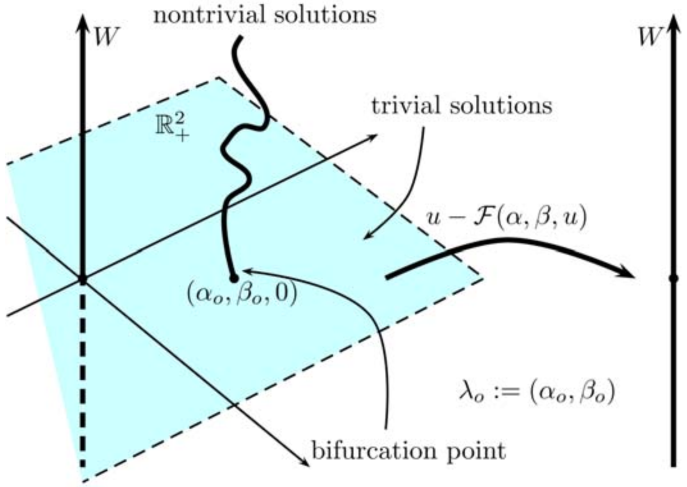

Fig. 1. Hopf bifurcation as a two-parameter fixed-point problem in functional spaces.

4.3. S^1-degree method for Hopf bifurcation problem

It is clear that every point $(\alpha, \beta, 0) \in \mathbb{R}^2_+ \times W$ is a solution to Eq. (87) (called a *trivial solution*). Denote the set $\mathbb{R}^2_+ \times \{0\} \subset \mathbb{R}^2_+ \times W$ by M. We would like to identify the so-called *bifurcation points* to (87), i.e. the trivial solutions $(\alpha_o, \beta_o, 0) \in M$ such that in every neighborhood of $(\alpha_o, \beta_o, 0)$ there is a non-trivial solution $(\alpha, \beta, u) \in \mathbb{R}^2_+ \times W$. Actually, in the case $(\alpha_o, \beta_o, 0) \in M$ is a bifurcation point, there is a "branch" in $\mathbb{R}^2_+ \times W$ of non-trivial solutions bifurcating from the trivial solution $(\alpha_o, \beta_o, 0) \in M$. The bifurcation problem for Eq. (87) is illustrated on Fig. 1.

Necessary condition for the occurrence of Hopf bifurcation By the implicit function theorem, the *necessary condition* for the point $(\alpha_o, \beta_o, 0)$ to be a bifurcation point, is that the linear operator

$$\mathrm{Id} - D_u\mathcal{F}(\alpha_o, \beta_o, 0) : W \to W$$

is not an isomorphism. In such a case, we say that $(\alpha_o, \beta_o, 0) \in M$ is a W*-singular point*. It follows directly from the definition of the map $\mathcal{F}$ that

$$a(\alpha, \beta) := \mathrm{Id} - D_u\mathcal{F}(\alpha, \beta, 0) = \mathrm{Id} - (L + K)^{-1}\left[\frac{1}{\beta} N_{D_x f}(\alpha, 0) + K\right], \tag{88}$$

where the operator $N_{D_x f}(\alpha, 0)$ is the Nemytsky operator of $D_x f(\alpha, 0)$, defined by

$$\big(N_{D_x f}(\alpha, 0) j(u)\big)(t) := D_x f(\alpha, 0) j(u)(t), \quad u \in W.$$

Clearly, $a(\alpha,\beta)(V)\subset V$ and $a(\alpha,\beta)(W_l)\subset W_l$, for all $l=1,2,3,\dots$. Put

$$a_0(\alpha,\beta):=a(\alpha,\beta)|_V,\quad a_l(\alpha,\beta):=a(\alpha,\beta)|_{W_l},\quad l=1,2,3,\dots. \tag{89}$$

It is clear that for a constant function $\bar{u}\in V\subset W$,

$$a_0(\alpha,\beta)\bar{u}=-\frac{1}{\beta}D_x f(\alpha,0)\bar{u}, \tag{90}$$

and for $e^{ilt}\cdot z\in W_l$, where $z=x+iy$, $x,y\in V$, we have (see (74) and (79))

$$a_l(\alpha,\beta)=\frac{1}{il\beta}\Delta_\alpha(il\beta). \tag{91}$$

Consequently, if $(\alpha_o,\beta_o,0)$ is a W-singular point, then at least one of the linear operators $a_l(\alpha_o,\beta_o)$, $l=0,1,2,\dots$, cannot be an isomorphism. In order to exclude the possibility for the occurrence of the so-called steady-state bifurcation (i.e. a bifurcation of constant solutions), we assume that the operator (90) is an isomorphism, i.e.

$$\det D_x f(\alpha_o,0)\neq 0. \tag{92}$$

Using (89)–(92) one can easily establish

PROPOSITION 4.1 (Necessary condition for Hopf bifurcation). *Assume the operator* $a(\alpha_o,\beta_o)\colon W\to W$ *(see* (88)*) is not an isomorphism for some* $(\alpha_o,\beta_o)\in\mathbb{R}\times\mathbb{R}_+$*, and suppose condition* (92) *is satisfied. Then, the characteristic equation* (75) *has a purely imaginary root* $il\beta_o$ *for* $\alpha=\alpha_o$ *and some* $l\in\mathbb{N}$.

DEFINITION 4.2.

(i) A point $(\alpha_o,x_o)\in\mathbb{R}\oplus\mathbb{R}^N$ is called a *center* for the system (71), if its characteristic equation (75) has a purely imaginary characteristic value $i\beta_o$ ($\beta_o>0$) for $\alpha=\alpha_o$.

(ii) A center (α_o,x_o) for the system (71) is called *isolated* if it is the only center for (71) in a certain neighborhood of (α_o,x_o) in $\mathbb{R}\oplus V$.

Sufficient conditions for the occurrence of Hopf bifurcation In what follows, it is convenient to identify $\mathbb{R}^2$ with $\mathbb{C}$, and instead of writing $(\alpha,\beta)\in\mathbb{R}^2$, we use the notation $\lambda=\alpha+i\beta$. In particular, we write $\lambda_o=\alpha_o+i\beta_o$.

Assume $(\alpha_o,0)$ is an isolated center for the system (71) with $\lambda_o=\alpha_o+i\beta_o$ (see Definition 4.2). Then, the point $(\lambda_o,0)\in\mathbb{R}^2_+\times W$ is an isolated W-singular point of $\mathfrak{F}$ (cf. (86)), i.e. for a sufficiently small $\varepsilon>0$, the linear operator $a(\lambda)=\mathrm{Id}-D_u\mathcal{F}(\lambda,0)\colon W\to W$, where $\lambda=\alpha+i\beta$ and $|\lambda-\lambda_o|<\varepsilon$, is not an isomorphism only if $\lambda=\lambda_o$. Consequently, by the implicit function theorem, there exists $r>0$ such that for all points $(\lambda,u)\in\mathbb{R}^2_+\oplus W$ with $|\lambda-\lambda_o|=\varepsilon$ and $0<\|u\|\leqslant r$, we have $u-\mathcal{F}(\lambda,u)\neq 0$. Define the set $\Omega\subset\mathbb{R}^2\oplus W$ by

$$\Omega=\bigl\{(\lambda,u)\in\mathbb{R}^2\oplus W\colon\ |\lambda-\lambda_o|<\varepsilon \text{ and } \|u\|<r\bigr\}. \tag{93}$$

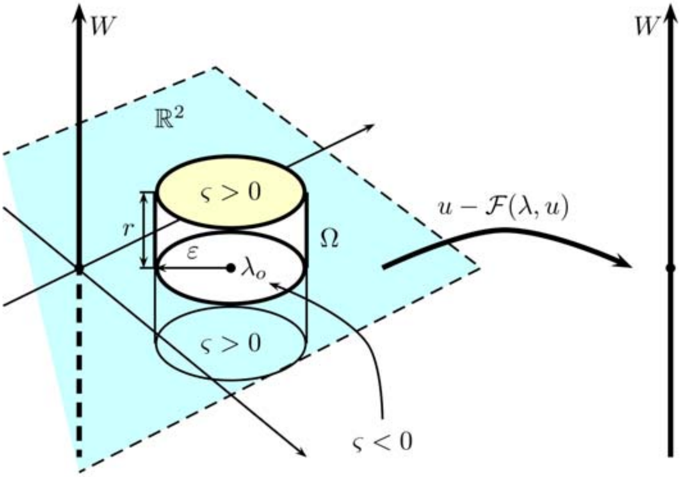

Fig. 2. Auxiliary function for Hopf bifurcation.

Put

$$\partial_0 := \overline{\Omega} \cap \left(\mathbb{R}^2 \times \{0\}\right) \quad \text{and} \quad \partial_r := \left\{(\lambda, u) \in \overline{\Omega}\colon \|u\| = r\right\}.$$

DEFINITION 4.3. An S^1-invariant continuous function $\varsigma : \overline{\Omega} \to \mathbb{R}$ is called an *auxiliary* function for $\mathfrak{F}$ in Ω, if

$$\begin{cases} \varsigma(\lambda, u) > 0 & \text{for } (\lambda, u) \in \partial_r, \\ \varsigma(\lambda, u) < 0 & \text{for } (\lambda, u) \in \partial_0 \end{cases}$$

(see Fig. 2).

The existence of an auxiliary function is provided by Proposition 3.9.

Take an auxiliary function ς and define the map $\mathfrak{F}_\varsigma : \overline{\Omega} \to \mathbb{R} \oplus W$ by

$$\mathfrak{F}_\varsigma(\lambda, u) := \left(\varsigma(\lambda, u), u - \mathcal{F}(\lambda, u)\right), \quad (\lambda, u) \in \overline{\Omega}. \tag{94}$$

Since $\mathfrak{F}_\varsigma(\lambda, u) \neq 0$ for $(\lambda, u) \in \partial\Omega$, it follows that $\mathfrak{F}_\varsigma$ is an Ω-admissible S^1-equivariant compact field, so the Leray–Schauder S^1-equivariant degree $S^1\text{-Deg}(\mathfrak{F}_\varsigma, \Omega)$ is well-defined.

THEOREM 4.4. *Given the system* (71), *assume conditions* (72) *and* (92) *are satisfied*. *Suppose*, *further*, $(\alpha_o, 0)$ *is an isolated center for* (71) (*cf. Definition* 4.2). *Take* $\mathfrak{F}$ *defined by* (86) *and construct* Ω *according to* (93). *Let* $\varsigma : \overline{\Omega} \to \mathbb{R}$ *be an auxiliary function* (*see Definition* 4.3) *and let* $\mathfrak{F}_\varsigma$ *be defined by* (94). *Assume, finally,* $S^1\text{-Deg}(\mathfrak{F}_\varsigma, \Omega) \neq 0$.

Then, there exists a branch of nontrivial solutions bifurcating from the point $(\lambda_o, 0) \in \Omega$. *More precisely, the closure of the set composed of all non-trivial solutions* $(\lambda, u) \in \Omega$ *to* (87), *i.e.*

$$\overline{\{(\lambda, u) \in \Omega\colon\ u - \mathcal{F}(\lambda, u) = 0,\ u \neq 0\}},$$

contains a compact connected subset C *such that*

$$(\lambda_o, 0) \in C \quad \text{and} \quad C \cap \partial_r \neq \emptyset.$$

The main ingredients of the proof of Theorem 4.4 are: invariant Urysohn function techniques, Zorn lemma and the following statement, which is an immediate consequence of Theorem 3 from [97], p. 170.

LEMMA 4.5. *Let* X *be a metric space,* $A, B \subset X$ *two disjoint closed sets in* X*, and* K *a compact set in* X *such that* $K \cap A \neq \emptyset \neq K \cap B$. *If the set* K *does not contain a connected component* K_o *such that* $K_o \cap A \neq \emptyset \neq K_o \cap B$, *then there exist two open disjoint sets* V_1 *and* V_2 *such that* $A \cup B \cup K \subset V_1 \cup V_2$, $A \subset V_1$ *and* $B \subset V_2$.

4.4. *Deformation of the map $\mathfrak{F}_\varsigma$: Reduction to a product map*

Theorem 4.4 reduces the study of the Hopf bifurcation for (71) to computing S^1-Deg$(\mathfrak{F}_\varsigma, \Omega)$. In this subsection, we deform $\mathfrak{F}_\varsigma$ to a field with "more computable" S^1-degree.

Complementing function and linearization Replace the set Ω (resp. the auxiliary function ς) with the set Ω_1 (resp. the so-called *complementing function* $\tilde{\varsigma} : \overline{\Omega_1} \to \mathbb{R}$) defined as

$$\Omega_1 := \left\{(\lambda, u) \in \mathbb{C} \oplus W\colon\ \frac{\varepsilon}{4} < |\lambda - \lambda_o| < \varepsilon,\ \|u\| < r\right\}. \tag{95}$$

Respectively,

$$\tilde{\varsigma} := |\lambda - \lambda_o|\big(\|u\| - r\big) + \|u\| + \varepsilon\frac{r}{2}. \tag{96}$$

For each $(\lambda, u) \in \Omega_1$, put

$$\eta(\lambda) := \lambda_o + \frac{\varepsilon(\lambda - \lambda_o)}{2|\lambda - \lambda_o|} \tag{97}$$

and define the map $\tilde{\mathfrak{F}} : \overline{\Omega_1} \to \mathbb{R} \oplus W$ by

$$\tilde{\mathfrak{F}}(\lambda, u) := \big(\tilde{\varsigma}(\lambda, u), a\big(\eta(\lambda)\big)u\big), \tag{98}$$

where $a(\cdot)$ is given by (88). Obviously, the map (98) is Ω_1-admissible S^1-equivariant and (by excision and homotopy property of twisted degree)

$$S^1\text{-Deg}(\tilde{\mathfrak{F}}, \Omega_1) = S^1\text{-Deg}(\mathfrak{F}_\varsigma, \Omega). \tag{99}$$

Finite-dimensional normalization Obviously, one may consider $a(\eta(\cdot))$ from (98) as a continuous map

$$\left\{\lambda \in \mathbb{C}\colon \frac{\varepsilon}{4} < |\lambda - \lambda_o| < \varepsilon\right\} \overset{a(\eta(\cdot))}{\longrightarrow} GL_c^{S^1}(W), \tag{100}$$

where $GL_c^{S^1}(W)$ stands for the group of S^1-equivariant linear completely continuous fields in W. Put

$$\Sigma := \left\{\lambda \in \mathbb{C}\colon |\lambda - \lambda_o| = \frac{\varepsilon}{2}\right\}. \tag{101}$$

By (97), the map (100) is completely determined by its restriction to $\Sigma \simeq S^1$. Denote by $\bar{a}(\cdot)$ the restriction of (100) to (101). Also, given $m \in \mathbb{N}$, define $W^m := V \oplus \bigoplus_{l=1}^m W_l \subset W$. Using the standard compactness argument, one can easily show

PROPOSITION 4.6. *There exists $m \in \mathbb{N}$ such that*:

(i) $W = W^m \oplus (W^m)^\perp$;

(ii) *for any $\lambda \in \Sigma$, the map $\tilde{a}(\lambda)$, defined by $\tilde{a}(\lambda) := \bar{a}(\lambda)|_{W^m} + \operatorname{Id}|_{(W^m)^\perp}$, belongs to $GL_c^{S^1}(W)$*;

(iii) *the map $\mathfrak{F}_2 : \overline{\Omega}_1 \to \mathbb{R} \oplus W$, defined by $\mathfrak{F}_2(\lambda, u) := (\tilde{\varsigma}(\lambda, u), \tilde{a}(\eta(\lambda))u)$, is the compact equivariant Ω_1-admissible field* (*cf.* (95));

(iv) S^1-Deg$(\tilde{\mathfrak{F}}, \Omega_1) = S^1$-Deg$(\mathfrak{F}_2, \Omega_1)$ (*cf.* (99)).

Isotypical deformations and finite-dimensional reduction Consider the map $\tilde{a}$ defined in Proposition 4.6(ii) more intently. Given $\lambda \in \Sigma$, put

$$\tilde{a}_0(\lambda) := \tilde{a}(\lambda)|_V; \qquad \tilde{a}_l(\lambda) := \tilde{a}(\lambda)|_{W_l}, \quad l > 0.$$

It follows immediately from (88)–(90), (92), that the map $\tilde{a}_0 : \Sigma \to GL(V) = GL(N, \mathbb{R})$ is homotopic to a constant map

$$a_0(\lambda_o) := -\frac{1}{\beta_o} D_x f(\alpha_o, 0), \tag{102}$$

where $\lambda_o = \alpha_o + \mathrm{i}\beta_o$.

Further, $\tilde{a}_l(\lambda) : W_l \to W_l$ is S^1-equivariant, therefore, $\tilde{a}_l(\lambda) \in GL^{S^1}(W_l) \simeq GL(N, \mathbb{C})$ (cf. Proposition 2.9). Thus, the map $\tilde{a}_l : \Sigma \to GL(N, \mathbb{C})$ determines an element $\mu \in$

$\pi_1(GL(N,\mathbb{C}))$. By Proposition 3.35(ii), μ contains a representative $b_l:\Sigma\to GL(N,\mathbb{C})$ of the form

$$b_l(\lambda)=\begin{bmatrix}(\lambda-\lambda_o)^{\mathfrak{k}_l} & 0 & \dots & 0\\ 0 & 1 & \dots & 0\\ \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & \dots & 1\end{bmatrix}:\mathbb{C}^N\to\mathbb{C}^N, \tag{103}$$

where $\mathfrak{k}_l$ is an integer.

Using Proposition 4.6(i), (ii), (102) and (103), define the map $\hat{a}:\Sigma\to GL_c^{S^1}(W)$ by

$$\hat{a}(\lambda):=a_0(\lambda_o)+\bigoplus_{l=1}^{m}b_l(\lambda)+\mathrm{Id}\,|_{(W^m)^\perp}, \tag{104}$$

and the compact S^1-equivariant field $\hat{\mathfrak{F}}:\overline{\Omega}_1\to W$ by $\hat{\mathfrak{F}}(\lambda,u):=(\tilde{\varsigma}(\lambda,u),\hat{a}(\eta(\lambda))u)$. Put $\Omega_o:=\Omega_1\cap(\mathbb{C}\oplus V\oplus\bigoplus_{l=1}^m W_l)$ and consider the map $\mathfrak{F}_o:=\hat{\mathfrak{F}}|_{\overline{\Omega_o}}$. By construction of the Leray–Schauder equivariant degree and the suspension property,

$$S^1\text{-Deg}(\mathfrak{F}_2,\Omega_1)=S^1\text{-Deg}(\mathfrak{F}_o,\Omega_o). \tag{105}$$

Product formula for S^1-Deg$(\mathfrak{F}_\varsigma,\Omega)$ Take $\Omega_*:=B\times\Omega_{o*}$, where $\Omega_{o*}:=\Omega_o\cap(\mathbb{C}\oplus\bigoplus_{l=1}^m W_l)$ and B is the unit ball in V, and define the map $\mathfrak{F}_{o*}:\overline{\Omega_{o*}}\to\mathbb{R}\oplus\bigoplus_{l=1}^m W_l$ by

$$\mathfrak{F}_{o*}(\lambda,v):=\left(\tilde{\varsigma}(\lambda,v),\bigoplus_{l=1}^{m}b_l\big(\eta(\lambda)\big)v_l\right)$$

(here v_l is an orthogonal projection of $v\in\bigoplus_{l=1}^m W_l$ to W_l (cf. (103))). Next, take the product map

$$\mathfrak{F}_*:=a_0(\lambda_o)\times\mathfrak{F}_{o*}:\overline{B\times\Omega_{o*}}\to V\oplus\left(\mathbb{R}\oplus\bigoplus_{l=1}^{m}W_l\right)$$

(see (102)). Using Theorem 3.48 and Remark 3.49, one obtains

$$S^1\text{-Deg}(\mathfrak{F}_o,\Omega_o)=S^1\text{-Deg}(\mathfrak{F}_*,\Omega_*)=\deg\big(a_0(\lambda_o),B\big)\cdot S^1\text{-Deg}(\mathfrak{F}_{o*},\Omega_{o*}),$$

where “deg” stands for the usual Brouwer degree. Observe, $\deg(a_0(\lambda_o),B)=\operatorname{sign}\det a_0(\lambda_o)$. Therefore, by applying Proposition 3.34, Lemma 3.37 and Theorem 3.39, we obtain

PROPOSITION 4.7. *Under the assumptions and notations of Theorem* 4.4, *one has*:

$$S^1\text{-Deg}(\mathfrak{F}_\varsigma,\Omega)=\operatorname{sign}\det a_0(\lambda_o)\cdot\sum_{l=1}^{m}\mathfrak{k}_l(\mathbb{Z}_l), \tag{106}$$

where a_0 *is given by* (90) *and the numbers* $\mathfrak{k}_l$ *are defined by*

$$\mathfrak{k}_l = \deg\bigl(\det_{\mathbb{C}}(a_l), \widetilde{D}\bigr) \tag{107}$$

for a_l *given by* (91) *and*

$$\widetilde{D} := \bigl\{\lambda \in \mathbb{C}\colon |\lambda - \lambda_o| < \varepsilon\bigr\}. \tag{108}$$

4.5. *Crossing numbers*

Under the assumption that one is able to effectively compute the numbers $\mathfrak{k}_l$ in formula (107), Proposition 4.7 together with Theorem 4.4 provide an effective way to study the Hopf bifurcation for the system (71). Fortunately, this task can be accomplished by using the information related to the S^1-equivariant spectral decomposition of $D_x f(\alpha, 0)$.

It is convenient to replace the set $\widetilde{D}$ in Proposition 4.7 with a set D defined by

$$D := \bigl\{\lambda = \alpha + \mathrm{i}\beta \in \mathbb{C}\colon \max\bigl\{|\alpha - \alpha_o|, |\beta - \beta_o|\bigr\} < \varepsilon\bigr\} \tag{109}$$

with, possibly, smaller ε. By excision and homotopy properties of Brouwer degree,

$$\mathfrak{k}_l = \deg\bigl(\det_{\mathbb{C}}(a_l), D\bigr).$$

Clearly, if the number $\mathrm{i}l\beta_o$ is not a root of the characteristic equation, then $\mathfrak{k}_l = 0$. Suppose, therefore, that $\mathrm{i}l\beta_o$ is a root of the characteristic equation (75) for $\alpha = \alpha_o$. Since $(\alpha_o, 0)$ is an isolated center, we can assume, without loss of generality, that the number ε in (109) is so small that for every α satisfying $0 < |\alpha - \alpha_o| < \varepsilon$, there is no purely imaginary root $\mathrm{i}\beta'$ of (75) with $|\beta' - l\beta_o| \leqslant \varepsilon$. Also, there exists $\delta > 0$ such that there are no characteristic roots $\tau + \mathrm{i}\beta$ of Eq. (75) for $|\alpha - \alpha_o| \leqslant \varepsilon$ belonging to the boundary of the set

$$S := \bigl\{\tau + \mathrm{i}\beta\colon 0 < \tau < \delta, |\beta - l\beta_o| < \varepsilon\bigr\}, \tag{110}$$

except for the root $\mathrm{i}l\beta$ corresponding to $\alpha = \alpha_o$ (see Fig. 3).

Using a simple Brouwer degree argument, one can show that

$$\mathfrak{k}_l = \deg(\det_{\mathbb{C}} \Delta_{\alpha_-}, S) - \deg(\det_{\mathbb{C}} \Delta_{\alpha_+}, S) \quad (\alpha_\pm := \alpha_o \pm \varepsilon). \tag{111}$$

DEFINITION 4.8. Define the following integers

$$\mathfrak{t}_l^\pm(\alpha_o, \beta_o) := \deg(\det_{\mathbb{C}} \Delta_{\alpha_\pm}, S),$$

and

$$\mathfrak{t}_l(\alpha_o, \beta_o) := \mathfrak{t}_l^-(\alpha_o, \beta_o) - \mathfrak{t}_l^+(\alpha_o, \beta_o). \tag{112}$$

The integer $\mathfrak{t}_l := \mathfrak{t}_l(\alpha_o, \beta_o)$ is called the *l-th isotypical crossing number* at (α_o, β_o).

$il\beta$
S
S
$\mathfrak{t}_l^- = 5$
$\mathfrak{t}_l^+ = 3$
$\mathfrak{t}_l = 5 - 3 = 2$

Fig. 4. The l-th isotypical crossing number.

The crossing number $\mathfrak{t}_l = \mathfrak{t}_l^- - \mathfrak{t}_l^+$ has a very simple interpretation. In the case i$l\beta_o$ is an eigenvalue of the matrix $D_x f(\alpha_o, 0)$, the number $\mathfrak{t}_l^-$ counts the number of all the eigenvalues (with multiplicity) in the set S before α crosses the value α_o, and the number $\mathfrak{t}_l^+$ counts the eigenvalues in S after α crosses α_o. The difference, which is exactly the number $\mathfrak{t}_l$, represents the net number of the eigenvalues which ‘escaped’ (if $\mathfrak{t}_l$ is positive) or ‘entered’ (if $\mathfrak{t}_l$ is negative) the set S when α was crossing α_o. This situation is illustrated on Fig. 4.

4.6. *Conclusions*

Return to the system (71). Take an isolated center $(\alpha_o, 0)$ corresponding to the purely imaginary characteristic root iβ_o, $\beta_0 > 0$. Then, Theorem 4.4 and Proposition 4.7 show that the equivariant degree S^1-Deg$(\mathfrak{F}_\varsigma, \Omega)$ is a *local Hopf bifurcation invariant* describing a possible occurrence of the bifurcation. Namely, the non-zero components of the equivariant degree provide the information about the existence of branches of non-constant periodic solutions to (71) bifurcating from the point $(\alpha_o, 0)$ (with the limit frequency β_o).

Furthermore, formulae (110)–(112), in compliance with Theorem 4.4 and Proposition 4.7, allow us to formulate an effective sufficient condition for the occurrence of the Hopf bifurcation in terms of the right-hand side of the system (71) only. Namely,

THEOREM 4.9. *Let* $V := \mathbb{R}^N$ *and let* $f : \mathbb{R} \oplus V \to V$ *and* $\alpha_o \in \mathbb{R}$ *satisfy the following conditions*:

(i) f *is of class* C^1;
(ii) $f(\alpha, 0) = 0$ *for all* $\alpha \in \mathbb{R}$;
(iii) $\det D_x f(\alpha_o, 0) \neq 0$, *where* $D_x f$ *denotes the derivative of* f *with respect to* $x \in V$;
(iv) $(\alpha_o, 0)$ *is an isolated center for the system* (71) *with* $\mathrm{i}\beta_o$ $(\beta_o > 0)$ *being the corresponding characteristic root* (*cf. Definition* 4.2 *and formulae* (74), (75));
(v) $\mathfrak{t}_1(\alpha_o, \beta_o) = \mathfrak{t}_1^-(\alpha_o, \beta_o) - \mathfrak{t}_1^+(\alpha_o, \beta_o) \neq 0$ (*see formulae* (110)–(112)).

Then, there exists a sequence (*in fact, it is a connected branch*) *of non-constant* $\frac{2\pi}{\beta_n}$-*periodic*[1] *solutions* $x_{\alpha_n}(t)$ *of the system* (71) (*with* $\alpha = \alpha_n$) *such that*

$$\begin{cases} \alpha_n \to \alpha_o, \\ x_{\alpha_n}(t) \to 0, \end{cases} \quad \text{as } n \to \infty.$$

PROOF. By conditions (i), (ii) and (iv), one can associate to (α_0, β_o) the degree $S^1\text{-Deg}(\mathfrak{F}_\varsigma, \Omega)$ (cf. formulae (93) and (94)). By Proposition 4.7 and formulae (110)–(112),

$$S^1\text{-Deg}(\mathfrak{F}_\varsigma, \Omega) = \operatorname{sign}\det a_0 \sum_{l=1}^{m} \mathfrak{k}_l(\mathbb{Z}_l) = \operatorname{sign}\det a_0 \sum_{l=1}^{m} \mathfrak{t}_l(\alpha_o, \beta_o)(\mathbb{Z}_l)$$

for some $m \geqslant 1$. By condition (v), $\mathfrak{t}_1(\alpha_o, \beta_o) \neq 0$, and the conclusion follows from Theorem 4.4 (condition (iii) excludes possible steady-state bifurcation). □

4.7. *Bibliographical remarks*

The standard approach to attack the Hopf bifurcation problem occurring in ODEs is based on the use of the Central Manifold theorem (allowing a reduction to the two-dimensional case) and further studying the properties of the Poincaré map associated with the induced system (an excellent exposition of this concept is presented in [113], see also [8,68,75]). Other techniques for studying Hopf bifurcation problems, which are based on Lyapunov–Schmidt reduction, normal forms and applications of the singularity theory can be found in [33,34,64,111]. The idea of a crossing number $\mathfrak{t}$ can be traced back to [2], where the framed bordism method was used to show that, if $\mathfrak{t}$ is odd, then a Hopf bifurcation occurs. The general result stating that, if $\mathfrak{t} \neq 0$ then a Hopf bifurcation takes place, was proved with the use of the Fuller index in [35]. One should point out that the framed bordism invariants and Fuller index can be expressed in terms of the equivariant degree (cf. [81,19]). The S^1-equivariant degree approach to the above problem described in this section was discussed in [61,93,19] (see also [46,49,81,95]). On the other hand, for Hamiltonian systems (resp. systems with first integral), important results were obtained by N.E. Dancer in [39] (resp. by E.N. Dancer and J.F. Toland in [40,42,41]).

---

[1] We do not assume here that $\frac{2\pi}{\beta_n}$ is a minimal period.

5. Hopf bifurcation problem for ODEs with symmetries

5.1. *Symmetric Hopf bifurcation and local bifurcation invariant*

Statement of the problem In this section, we extend the setting and methods developed in Section 4 to discuss the Hopf bifurcation phenomenon for the system (71) admitting a certain compact Lie group of symmetries. More precisely, suppose $V := \mathbb{R}^N$ is an orthogonal representation of a compact Lie group Γ and assume that

(A0) $f : \mathbb{R} \oplus V \to V$ is Γ-equivariant.

Also, assume that f and $\alpha_o \in \mathbb{R}$ satisfy the hypotheses (i)–(iv) from Theorem 4.9.

We are interested in describing possible symmetries of non-constant periodic solutions to the system (71) bifurcating from the origin.

$\Gamma \times S^1$-Equivariant reformulation of the problem Following the same scheme as in the non-symmetric case (see Subsection 4.2), we start with the normalization of the period (see (76) and (77)) and setting in functional spaces (see (84)). Observe that the space $W = H^1(S^1; V)$ is a natural Hilbert isometric $\Gamma \times S^1$-representation with the action given by $((\gamma, \zeta)u)(t) = \gamma u(t + \tau)$, $t \in \mathbb{R}$, $\gamma \in \Gamma$, $\zeta = e^{i\tau} \in S^1$, $u \in W$. In the same way, the space $\mathcal{C} = C(S^1; V)$ is a Banach isometric G-representation. Further, consider $\mathbb{R}^2_+$ (identified with the subspace of $\mathbb{C}$) as a trivial G-space. Then, all the operators L, j, N_f, and K (cf. (81)–(83) and (85)) turn out to be G-equivariant. Consequently, the system (71) translates as the G-equivariant fixed-point problem (87).

G-isotypical decomposition of W The S^1-isotypical decomposition (80) of W is clearly G-invariant, therefore we can use it to construct the G-isotypical decomposition of W. Consider the real (resp. complex) Γ-isotypical decomposition of V (resp. V^c):

$$V = V_0 \oplus V_1 \oplus \cdots \oplus V_r, \qquad V^c = U_0 \oplus U_1 \oplus \cdots \oplus U_s, \tag{113}$$

where the isotypical components V_i (resp. U_j) are modeled on the real (resp. complex) Γ-irreducible representations $\mathcal{V}_i$ (resp. $\mathcal{U}_j$). Notice that it is possible that there is a different number of isotypical components in the isotypical decompositions of V and V^c. The isotypical components of W_l, $l \geqslant 1$, are easily obtained (see Remark and Notation 2.6):

$$W_l = V_{0,l} \oplus V_{1,l} \oplus \cdots \oplus V_{s,l}, \tag{114}$$

where the components $V_{j,l} := {}^{l}U_j$, $j = 0, 1, \ldots, s$, are modeled on the irreducible G-representation $\mathcal{V}_{j,l}$. In this way, we obtain the following G-isotypical decomposition of W:

$$W = [V_0 \oplus V_1 \oplus \cdots \oplus V_r] \oplus \overline{\bigoplus_{l=1}^{\infty} (V_{0,l} \oplus V_{1,l} \oplus \cdots \oplus V_{s,l})}. \tag{115}$$

Dominating orbit types The following notion will be used to estimate the *minimal number* of different periodic solutions (as well as their symmetries) to the system (71) (see Theorem 5.4).

DEFINITION 5.1. An orbit type (H) in W is called *dominating,* if (H) is maximal (with respect to the usual order relation (10)) in the class of all φ-twisted *one-folded* orbit types in W (i.e. $H = K^{\varphi}$, where $\varphi : K \to S^1$ is a homomorphism, and $\dim W(K) = 0$ (see Section 3.3 for more details)).

REMARK 5.2. Let (H) be a dominating orbit type in W. Using the maximality property of (H), it is easy to see that there exists an irreducible subrepresentation $\mathcal{V} \subset W$ and a non-zero vector $u \in \mathcal{V}$ such that $G_u = H$. Consequently, the dominating orbit types in W can be easily recognized from the isotypical decomposition of W and lattices of orbit types of the corresponding to this decomposition irreducible G-representations.

REMARK 5.3. Assume there is a solution $u_o \in W$ to (77) (for $\alpha = \alpha_o$ and some $\beta > 0$), for which one has $G_{u_o} \supset H_o$. If (H_o) is a dominating orbit type in W with $H_o = K^{\varphi}$ for some $K \subset \Gamma$ and $\varphi : K \to S^1$, then, by maximality condition, $(G_{u_o}) = (K^{\varphi,l})$ with $l \geqslant 1$, and the corresponding orbit $G(u_o)$ is composed of exactly $|G/G_{u_o}|_{S^1}$ different periodic functions (where $|Y|_{S^1}$ denotes the number of S^1-orbits in Y). It is easy to check that the number of S^1-orbits in G/G_{u_o} is $|\Gamma/K|$ (where $|X|$ stands for the number of elements in X).

On the other hand, suppose that x_o is, say, a p-periodic solution to (71) canonically corresponding to the above u_o. It follows from the definition of l-folding and $\Gamma \times S^1$-action on W that x_o is also a $\frac{p}{l}$-periodic solution to (71). The pair $(x_o, \frac{p}{l})$ canonically determines an element $u_o' \in W$ being a solution to (77) (for $\alpha = \alpha_o$ and some β') satisfying the condition $G_{u_o'} = H_o$. In this way, we obtain that (71) has at least $|\Gamma/K|$ different periodic solutions with the orbit type exactly (H_o).

Sufficient conditions for symmetric Hopf bifurcation Similarly to the non-equivariant case, define the set Ω by (93). Since W is an isometric G-representation, Ω is clearly G-invariant. Combining the standard Urysohn function techniques (cf. Proposition 3.9) with Definition 4.3, construct a G-invariant auxiliary function $\varsigma : \overline{\Omega} \to \mathbb{R}$. Then, define the map $\mathfrak{F}_{\varsigma} : \overline{\Omega} \to \mathbb{R} \oplus W$ by (94), which is a G-equivariant Ω-admissible compact field. Therefore, one can assign to $\mathfrak{F}_{\varsigma}$ the twisted degree $G\text{-Deg}^{t}(\mathfrak{F}_{\varsigma}, \Omega)$.

Combining the properties of the twisted degree with Remark 5.3 and Lemma 4.5 (cf. Theorem 4.4), one can easily establish

THEOREM 5.4. *Given the system* (71), *assume conditions* (i)–(iv) *from Theorem* 4.9 *and condition* (A0) *to be satisfied. Take* $\mathfrak{F}$ *defined by* (86) *and construct* Ω *according to* (93). *Let* $\varsigma : \overline{\Omega} \to \mathbb{R}$ *be a* G*-invariant auxiliary function* (*see Definition* 4.3) *and let* $\mathfrak{F}_\varsigma$ *be defined by* (94).

(i) *Assume* $G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) \neq 0$, *i.e.*

$$G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) = \sum_{(H)} n_H(H) \quad \textit{and} \quad n_{H_o} \neq 0 \tag{116}$$

for some $(H_o) \in \Phi_1^t(G)$. *Then, there exists a branch of non-trivial solutions to* (71) *bifurcating from the point* $(\alpha_o, 0)$ (*with the limit frequency* $l\beta_o$ *for some* $l \in \mathbb{N}$). *More precisely, the closure of the set composed of all non-trivial solutions* $(\lambda, u) \in \Omega$ *to* (87), *i.e.*

$$\overline{\{(\lambda, u) \in \Omega\colon\ \mathfrak{F}(\lambda, u) = 0,\ u \neq 0\}}$$

contains a compact connected subset C *such that*

$$(\lambda_o, 0) \in C \quad \textit{and} \quad C \cap \partial_r \neq \emptyset, \quad C \subset \mathbb{R}^2_+ \times W^{H_o},$$

$(\lambda_o = \alpha_o + \mathrm{i}\beta_o)$ *which, in particular, implies that for every* $(\alpha, \beta, u) \in C$, *we have* $G_u \supset H_o$.

(ii) *If, in addition,* (H_o) *is a dominating orbit type in* W, *then there exist at least* $|G/H_o|_{S^1}$ *different branches of periodic solutions to Eq.* (71) *bifurcating from* $(\alpha_o, 0)$ (*with the limit frequency* $l\beta_o$ *for some* $l \in \mathbb{N}$). *Moreover, for each* (α, β, u) *belonging to these branches of* (*nontrivial*) *solutions one has* $(G_u) = (H_o)$ (*considered in the space* W).

REMARK 5.5.

(i) Since the order (10) on the set $\Phi_1^t(G)$ is partial, it is usually the case that there is more than one dominating orbit type in W contributing to the lower estimate of all bifurcating branches of solutions.

(ii) In addition, if there is also a coefficient $n_K \neq 0$ such that (K) is not a dominating orbit type, but $n_H = 0$ for all dominating orbit types (H) such that $(K) < (H)$, then we can also predict the existence of multiple branches by analyzing all the dominating orbit types (H) larger than (K). However, the exact orbit type of these branches (as well as the corresponding estimate) cannot be determined precisely.

Local bifurcation invariant Similarly to the non-equivariant case, the non-zero coefficient n_{H_o} in (116) indicates that in the subspace $\mathbb{R}^2_+ \oplus W^{H_o}$, there exists a branch of solutions to (87), which is “invariant” (i.e. does not disappear) under small *equivariant* perturbations of the map $\mathfrak{F}_\varsigma$. This observation justifies the following

DEFINITION 5.6. Put

$$\omega(\lambda_o) = \omega(\alpha_o, \beta_o) := G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) \tag{117}$$

and call it the *local equivariant topological bifurcation invariant* (or simply *local bifurcation invariant*) of the (bifurcation) point (α_o, β_o).

5.2. *Computation of local bifurcation invariant: Reduction to product formula*

Although the computations of the local bifurcation invariant (117) are, in general, parallel to the non-equivariant case (see Subsections 4.4 and 4.5), several (specifically equivariant) steps have substantial differences, which should be carefully explained.

Linearization and finite-dimensional reduction As in the non-equivariant case, we start with the linearization of the map $\mathfrak{F}_\varsigma$. Namely, using (95)–(97) and the linear map $a(\alpha, \beta)$ defined by (88), construct the map $\tilde{\mathfrak{F}} : \overline{\Omega_1} \to \mathbb{R} \oplus W$ by formula (98). Then,

$$G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) = G\text{-Deg}^t(\tilde{\mathfrak{F}}, \Omega_1).$$

Take Σ defined by (101) and construct W^m and $\mathfrak{F}_2 : \overline{\Omega_1} \to \mathbb{R} \oplus W$ as in Proposition 4.6. Obviously, W^m is G-invariant, so that $\mathfrak{F}_2$ is G-equivariant. Put $\Omega_o := \Omega_1 \cap (\mathbb{C} \oplus W^m)$ and $\mathfrak{F}_o := \mathfrak{F}_2|_{\overline{\Omega_o}}$. Then,

$$G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) = G\text{-Deg}^t(\mathfrak{F}_2, \Omega_1) = G\text{-Deg}^t(\mathfrak{F}_o, \Omega_o).$$

Product formula Put $W_{o*} := \mathbb{C} \oplus \bigoplus_{l=1}^m W_l$ and $\Omega_{o*} := \Omega_o \cap W_{o*}$. Then, without loss of generality, one can assume that $\Omega_o = B \times \Omega_{o*}$, where B is the unit ball in V, and, in addition, $\mathfrak{F}_o = a_0(\lambda_o) \times \mathfrak{F}_{o*}$, where $a_0(\lambda_o) : \overline{B} \to V$ is given by (90), $\lambda_o = \alpha_o + \mathrm{i}\beta_o$, and $\mathfrak{F}_{o*} : \overline{\Omega_{o*}} \to \mathbb{R} \oplus \bigoplus_{l=1}^m W_l$, is given by

$$\mathfrak{F}_{o*}(\lambda, u) = \left(\tilde{\varsigma}(\lambda, u), \bigoplus_{l=1}^{m} a_l\big(\eta(\lambda)\big)u \right), \tag{118}$$

where a_l is given by (91) (see also (88) and (89)).

Then, apply the multiplicativity property of the twisted G-equivariant degree (see Theorem 3.48) to obtain

$$G\text{-Deg}^t(\mathfrak{F}_\varsigma, \Omega) = \Gamma\text{-Deg}\big(a_0(\lambda_o), B\big) \cdot G\text{-Deg}^t(\mathfrak{F}_{o*}, \Omega_{o*}). \tag{119}$$

Computation of $\Gamma\text{-Deg}(a_0(\lambda_o), B)$ Consider the set $\sigma_- := \{\mu \in \sigma(a_0(\lambda_o)) : \mu < 0\}$, where $\sigma(a_0(\lambda_o))$ stands for the (real) spectrum of $a_0(\lambda_o)$ (observe, by the way, that there is a direct connection between σ_- and the set of positive eigenvalues of $D_x f(\alpha_o, 0)$). For every $\mu \in \sigma_-$, denote by $E(\mu) \subset V$ the eigenspace corresponding to μ. Since $E(\mu)$ is Γ-invariant, one can consider its Γ-isotypical decomposition

$$E(\mu) = E_0(\mu) \oplus E_1(\mu) \oplus \cdots \oplus E_r(\mu),$$

where the component $E_i(\mu)$ is modeled on the irreducible Γ-representation $\mathcal{V}_i$, $i = 0, 1, 2, \ldots, r$. Put

$$m_i(\mu) := \dim E_i(\mu)/\dim \mathcal{V}_i, \quad i = 0, 1, 2, \ldots, r. \tag{120}$$

The number $m_i(\mu)$ is called *$\mathcal{V}_i$-multiplicity* of the eigenvalue μ.

By applying the homotopy and multiplicativity properties (cf. Theorem 3.46),

$$\Gamma\text{-Deg}\big(a_0(\lambda_o), B\big) = \prod_{\mu\in\sigma_-} \prod_{i=0}^{r} (\deg_{\mathcal{V}_i})^{m_i(\mu)}. \tag{121}$$

5.3. *Computation of local bifurcation invariant: Reduction to crossing numbers and basic degrees*

In view of formulae (119) and (121), it remains to compute $G\text{-Deg}^t(\mathfrak{F}_{o*}, \Omega_{o*})$.

Isotypical representation of a_l Take the isotypical decomposition (114) and put $a_{j,l}(\lambda) := a_l(\eta(\lambda))|_{V_{j,l}} : V_{j,l} \to V_{j,l}$ ($j = 0, 1, \ldots, s$). Observe that for a fixed λ, the operator $a_{j,l}(\lambda)$ is a Γ-equivariant complex isomorphism, which can be represented (cf. Proposition 2.9) by a complex $n_j \times n_j$-matrix, where $n_j := \dim V_{j,l}/\dim \mathcal{V}_{j,l}$ (this number is the same for all $l = 1, 2, \ldots$). Put (cf. (113))

$$\Delta_{\alpha,j}(\lambda) := \Delta_\alpha(\lambda)|_{U_j} : U_j \to U_j. \tag{122}$$

Keeping in mind (91), denote by

$$\Delta^{\mathbb{C}}_{\alpha,j}(\lambda) : \mathbb{C}^{n_j} \to \mathbb{C}^{n_j}, \tag{123}$$

the $n_j \times n_j$-matrix representation of the operator $\Delta_{\alpha,j}(\lambda) : U_j \to U_j$ (cf. Proposition 2.9). Then,

$$a_{j,l}(\lambda) = \frac{1}{\mathrm{i}l\beta} \Delta^{\mathbb{C}}_{\alpha,j}(\mathrm{i}l\beta) \quad \text{with } \lambda = \alpha + \mathrm{i}\beta. \tag{124}$$

Isotypical deformations The obtained identification (124), (123) of $a_{j,l}(\cdot)$ and the fact that the linear group $GL^G(V_{j,l})$ is isomorphic to the complex linear group $GL(n_j, \mathbb{C})$, can be used to deform $a_{j,l}(\cdot)$ in a way similar to the non-equivariant case. Namely, put $\tilde{a}_{j,l}(\cdot) := a_{j,l}|_\Sigma$ (cf. (101)). Then, by Proposition 3.35, the homotopy class of the map $\tilde{a}_{j,l} : \Sigma \to GL(n_j, \mathbb{C})$ contains a representative $b_{j,l} : \Sigma \to GL(n_j, \mathbb{C})$ of the following form:

$$b_{j,l}(\lambda) = \begin{bmatrix} (\lambda - \lambda_o)^{\mathfrak{k}_{j,l}} & 0 & \ldots & 0 \\ 0 & 1 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & 1 \end{bmatrix} : \mathbb{C}^{n_j} \to \mathbb{C}^{n_j}, \tag{125}$$

where $\mathfrak{k}_{j,l}$ is an integer defined by

$$\mathfrak{k}_{j,l} = \deg(\det_{\mathbb{C}} \Delta^{\mathbb{C}}_{\alpha,j}, \widetilde{D}) \tag{126}$$

(cf. (103), (107) and (108)).

Using the identification (124), (123) and formula (125), define the map $\tilde{\mathfrak{F}}_{o*} : \overline{\Omega_{o*}} \to \mathbb{R} \oplus \bigoplus_{l=1}^{m} W_l$ by

$$\tilde{\mathfrak{F}}_{o*}(\lambda, v) := \left(\tilde{\varsigma}(\lambda, v), \bigoplus_{l=1}^{m} b_{j,l}\big(\eta(\lambda)\big) v_l \right) \tag{127}$$

(here v_l is an orthogonal projection of $v \in \bigoplus_{l=1}^{m} W_l$ to W_l). Combining formula (127) with Proposition 3.45 yields:

$$G\text{-Deg}^t(\mathfrak{F}_{o*}, \Omega_{o*}) = G\text{-Deg}^t(\tilde{\mathfrak{F}}_{o*}, \Omega_{o*}) = \sum_{j,l} \mathfrak{k}_{j,l} \deg_{\mathcal{V}_{j,l}}. \tag{128}$$

In this way (cf. (119), (121) and (128)), we have proved the following

PROPOSITION 5.7. *Let* $\mathfrak{F}_{\varsigma}$ *and* Ω *be as in Theorem* 5.4. *Take the isotypical decompositions* (113) *and* (114). *Then,*

$$G\text{-Deg}^t(\mathfrak{F}_{\varsigma}, \Omega) = \prod_{\mu \in \sigma_-} \prod_{i=0}^{r} (\deg_{\mathcal{V}_i})^{m_i(\mu)} \cdot \sum_{j,l} \mathfrak{k}_{j,l} \deg_{\mathcal{V}_{j,l}}, \tag{129}$$

where σ_- *denotes the* (*real*) *negative spectrum of the operator* $a_0(\lambda_o)$ (*see* (90)), $\deg_{\mathcal{V}_i}$ *is defined by* (63), $m_i(\mu)$ *stands for the* $\mathcal{V}_i$*-multiplicity of* μ (*cf.* (120)), $\mathfrak{k}_{j,l}$ *is given by* (126), $\deg_{\mathcal{V}_{j,l}}$ *is defined in* (60) ($j = 0, \ldots, s$ *and* $l = 1, \ldots, m$), *and the multiplication "$\cdot$" is taken in* $A_1^t(\Gamma \times S^1)$.

Crossing numbers To complete our computations of the local bifurcation invariant, we need to express the integers $\mathfrak{k}_{j,l}$ from (129) via the symmetric spectral properties of the operator $D_x f(\alpha, 0)$. To this end, we adopt the concept of crossing numbers to the equivariant setting.

Following the scheme used in the non-equivariant case, assume that $\mathrm{i}l\beta_o$ is a root of the characteristic equation and choose a small neighborhood S of $\mathrm{i}l\beta_o$ in the right half-plane of $\mathbb{C}$ (see (110)) such that for $|\alpha - \alpha_o| \leqslant \varepsilon$, the characteristic roots of Eq. (75) can only leave S through the 'exit' at the point $\mathrm{i}l\beta_o$ for $\alpha = \alpha_o$.

DEFINITION 5.8. Using (113) and the identification (124), (123), put

$$\mathfrak{t}^{\pm}_{j,l}(\alpha_o, \beta_o) := \deg(\det_{\mathbb{C}} \Delta^{\mathbb{C}}_{\alpha_\pm, j}, S)$$

and

$$\mathrm{t}_{j,l}(\alpha_o,\beta_o)=\mathrm{t}^{-}_{j,l}(\alpha_o,\beta_o)-\mathrm{t}^{+}_{j,l}(\alpha_o,\beta_o). \tag{130}$$

The integer (130) is called the $\mathcal{V}_{j,l}$*-isotypical crossing number* at (α_o,β_o) (cf. (112).

REMARK 5.9. The crossing number (130), if it is positive (resp. negative), indicates the algebraic count (with $\mathcal{U}_j$-multiplicities) of roots of the (isotypical) characteristic equation

$$\det\nolimits_{\mathbb{C}}\Delta_{\alpha,j}(\lambda)=0 \tag{131}$$

(i.e. the characteristic equation restricted to the isotypical component U_j of the space V^c (cf. (113)), which leave (resp. enter) the neighborhood S through the point $\mathrm{i}l\beta_o$ as α crosses α_0). For the system (71), the characteristic roots are the eigenvalues of the (complex) matrix $D_x f(\alpha,0)$. Thus, in order to determine the crossing number $\mathrm{t}_{j,l}(\alpha_o,\beta_o)$, one needs to verify what happens to the eigenvalues of $D_x f(\alpha,0)$ when α crosses α_o. For example, if there is one eigenvalue, which exits S through $\mathrm{i}l\beta_o$, and its $\mathcal{U}_j$-multiplicity is k, then $\mathrm{t}_{j,l}(\alpha_o,\beta_o)=k$.

Clearly,

$$\mathrm{t}_{j,l}(\alpha_o,\beta_o)=\mathrm{t}_{j,1}(\alpha_o,l\beta_o). \tag{132}$$

As in the non-equivariant case, a simple Brouwer degree argument leads to the relation

$$\mathfrak{t}_{j,l}=\mathrm{t}_{j,l}(\alpha_o,\beta_o). \tag{133}$$

In this way, by Proposition 5.7, we obtain the following computational formula for the local bifurcation invariant $\omega(\alpha_o,\beta_o)$.

PROPOSITION 5.10. *Under the notations of Proposition* 5.7, *we have*

$$\omega(\alpha_o,\beta_o)=\prod_{\mu\in\sigma_-}\prod_{i=0}^{r}(\deg_{\mathcal{V}_i})^{m_i(\mu)}\cdot\sum_{j,l}\mathrm{t}_{j,l}(\alpha_o,\beta_o)\deg_{\mathcal{V}_{j,l}}, \tag{134}$$

where $\mathrm{t}_{j,l}$ *is given by* (130).

5.4. *Summary of the equivariant degree method*

Theorem 5.4 together with Proposition 5.10 give an effective algorithm to classify symmetric branches of non-trivial periodic solutions to the Γ-symmetric system (77) (and, correspondingly, (71)) bifurcating from an isolated center $(\alpha_o,0)$. For the reader convenience, we sketch below the main steps one should follow.

(a) Take an isolated center $(\alpha_o, 0)$ for the system (71) with $\mathrm{i}\beta_o$ ($\beta_o > 0$) being the corresponding characteristic root (cf. Definition 4.2 and formulae (74) and (75)).

(b) Consider the operator $A := -\frac{1}{\beta_o} D_x f(\alpha_o, 0) : V \to V$, which is clearly Γ-equivariant, and put $\sigma_- := \{\mu \in \sigma(A) \colon \mu < 0\}$, where $\sigma(A)$ stands for the real spectrum of A. Notice that σ_- is composed of $-\frac{1}{\beta_o}\nu$, where ν is a positive eigenvalue of $D_x f(\alpha_o, 0)$.

(c) For every $\mu \in \sigma_-$ (or, equivalently, one can take the corresponding positive eigenvalue of $D_x f(\alpha_o, 0)$), consider the Γ-isotypical decomposition of the eigenspace $E(\mu)$:

$$E(\mu) = E_0(\mu) \oplus E_1(\mu) \oplus \cdots \oplus E_r(\mu),$$

where the component $E_i(\mu)$ is modeled on the irreducible Γ-representation $\mathcal{V}_i$, and evaluate the $\mathcal{V}_i$-multiplicity of μ, i.e. $m_i(\mu) = \dim E_i(\mu) / \dim \mathcal{V}_i$.

(d) Compute the element $\deg_0(\alpha_o, \beta_o) \in A(\Gamma)$ according to the formula:

$$\deg_0(\alpha_o, \beta_o) := \prod_{\mu \in \sigma_-} \prod_{i=0}^{r} (\deg_{\mathcal{V}_i})^{m_i(\mu)}. \tag{135}$$

(e) Find the (complex) Γ-isotypical decomposition of the complexification V^c, i.e.

$$V^c = U_0 \oplus U_1 \oplus \cdots \oplus U_s,$$

where the Γ-isotypical component U_j is modeled on the irreducible Γ-representation $\mathcal{U}_j$, and put $A_j(\alpha) := D_x f(\alpha, 0)|_{U_j}$ (here $D_x f(\alpha, 0)$ is considered as the corresponding complexification). Consider the set of all the purely imaginary eigenvalues of $A_j(\alpha_o)$ which are integer multiples of $\mathrm{i}\beta_o$:

$$\{\mathrm{i}\beta_o, \mathrm{i}k_1\beta_o, \dots, \mathrm{i}k_q\beta_o\},$$

where $k_p > 1$ are integers ($p = 1, \dots, q$).

(f) Compute the element $\deg_*(\alpha_o, \beta_o) \in A_1^t(G)$ defined as the following sum:

$$\deg_*(\alpha_o, \beta_o) = \sum_{j=0}^{s} \sum_{p=1}^{q} \mathfrak{t}_{j,k_p}(\alpha_o, \beta_o) \deg_{\mathcal{V}_{j,k_p}}, \tag{136}$$

where the numbers $\mathfrak{t}_{j,k_p}(\alpha_o, \beta_o) = \mathfrak{t}_{j,1}(\alpha_o, k_p\beta_o)$ are the $\mathcal{V}_{j,k_p}$-isotypical crossing numbers at (α_o, β_o) (cf. (132)). Obviously, all the numbers $\mathfrak{t}_{j,l}(\alpha_o, \beta_o)$ appearing in formula (134) and satisfying the condition $l \neq k_p$ ($p = 1, \dots, q$), are equal to zero.

(g) Compute the local bifurcation invariant $\omega(\alpha_o, \beta_o)$ for the system (71) according to the formula:

$$\omega(\alpha_o, \beta_o) = \deg_0(\alpha_o, \beta_o) \cdot \deg_*(\alpha_o, \beta_o) = \sum_{(H)} n_H(H), \tag{137}$$

where '$\cdot$' denotes the product in the $A(\Gamma)$-module $A_1^t(G)$.

(h) Let $\{(H_1), \dots, (H_n)\}$ be the set of all dominating orbit types in W such that the numbers n_{H_k}, $k = 1, \dots, n$, appearing in (137) are all non-zero. Then, for each $k = 1, \dots, n$, there exist at least $|\frac{G}{H_k}|_{S^1}$ different branches of non-trivial periodic solutions to (77) (with the limit frequency $l\beta_o$ for some $l \in \mathbb{N}$) bifurcating from $(\alpha_o, 0)$. Moreover, for each (α, β, u), belonging to these $|\frac{G}{H_k}|_{S^1}$ branches, one has $(G_u) = (H_k)$ (here, as usual, the symbol $|X|_{S^1}$ stands for the number of S^1-orbits in the set X). In particular, the number

$$\left|\frac{G}{H_1}\right|_{S^1} + \left|\frac{G}{H_2}\right|_{S^1} + \dots + \left|\frac{G}{H_n}\right|_{S^1}$$

gives a lower estimate for the number of branches of non-trivial solutions resulting in the (local) Hopf bifurcation in the system (77). In addition, if in formula (137) one has $n_{H_o} \neq 0$ for some *non-dominating* orbit type (H_o) in W, then Remark 5.5(ii) is applied.

5.5. *Usage of Maple© routines*

The last step of the equivariant degree method is the computation of the exact value of the local bifurcation invariant $\omega(\alpha_o, \beta_o)$ given by (134). Depending on the size of the group Γ, the number of related algebraic computations can be quite substantial and the usage of computer programming seems to be indispensable. We have created several Maple© routines, for selected groups Γ, that are able to complete these tasks, based on the properly prepared spectral data extracted from the characteristic equation (75).

Arranging equivariant spectral data We begin with the information related to the negative spectrum of the operator A (described in (b) and (c)). In order to simplify the computations of the factor (135) in formula (134), one can take advantage of the fact that $(\deg_{\mathcal{V}_i})^2 = (\Gamma)$, which is the unit in the Burnside ring $A(\Gamma)$. Therefore, it is sufficient to consider the numbers

$$\mathfrak{m}_i := \sum_{\mu \in \sigma_-} m_i(\mu), \quad \text{for } i = 0, 1, \dots, r,$$

and introduce the sequence $\{\varepsilon_0, \varepsilon_1, \dots, \varepsilon_r\}$, where

$$\varepsilon_i := \mathfrak{m}_i \bmod 2, \quad i = 0, 1, \dots, r.$$

Folding homomorphism Θ_l Define on generators $(K^{\varphi,k})$ an $A(\Gamma)$-module homomorphism $\Theta_l : A_1^t(\Gamma \times S^1) \to A_1^t(\Gamma \times S^1)$ by

$$\Theta_l\big[(K^{\varphi,k})\big] := (K^{\varphi,lk})$$

Table 2
Isotypical crossing numbers

Representation	Folding 1	Folding 2	…	Folding l
$\mathcal{U}_0$	$\mathfrak{t}_{0,1}(\alpha_o,\beta_o)$	$\mathfrak{t}_{0,2}(\alpha_o,\beta_o)$	…	$\mathfrak{t}_{0,l}(\alpha_o,\beta_o)$
$\mathcal{U}_1$	$\mathfrak{t}_{1,1}(\alpha_o,\beta_o)$	$\mathfrak{t}_{1,2}(\alpha_o,\beta_o)$	…	$\mathfrak{t}_{1,l}(\alpha_o,\beta_o)$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\mathcal{U}_s$	$\mathfrak{t}_{s,1}(\alpha_o,\beta_o)$	$\mathfrak{t}_{s,2}(\alpha_o,\beta_o)$	…	$\mathfrak{t}_{s,l}(\alpha_o,\beta_o)$

(see Subsection 3.6). Then,

$$\deg_{\mathcal{V}_{j,l}} = \Theta_l(\deg_{\mathcal{V}_{j,1}}). \tag{138}$$

The full exact value of the local bifurcation invariant $\omega(\alpha_o,\beta_o)$ (cf. (134)) can be obtained with the usage of the Maple© routines, by applying the following formula

$$\begin{aligned}\omega(\alpha_o,\beta_o) \\ = \sum_l \Theta_l\big[\texttt{showdegree}\,[\Gamma](\varepsilon_0,\varepsilon_1,\dots,\varepsilon_r,\mathfrak{t}_{0,l}(\alpha_o,\beta_o),\mathfrak{t}_{1,l}(\alpha_o,\beta_o),\dots, \\ \mathfrak{t}_{s,l}(\alpha_o,\beta_o))\big]\end{aligned} \tag{139}$$

(see Table 2).

5.6. *Bibliographical remarks*

Symmetric Hopf bifurcation was intensively studied during the last decades. The commonly used methods were based on generic approximation, transversality theory (cf. [51–53]), reduction to normal forms and special singularity theory (see the fundamental monographs [64,67], for the recent developments we refer to [31], see also [30,32,63,66]). The case of the symmetric Hopf bifurcation from the so-called "relative equilibria" was considered in [28,100–102,116,147]). One of the advantages of the singularity theory methods is that they allow to predict stability of the bifurcating branches, while the twisted degree method is not sensitive to stability. However, it is our belief that the latter method is easier to apply (in a standard way), allows to treat "large" groups of symmetries and can be completely computerized. The $\Gamma \times S^1$-equivariant settings for an ODEs system, relevant to our discussion, was studied in [18,19,81,91,93]. The notion of a dominating orbit type (which was introduced in [10]) is commonly known in the literature as "maximal". The Maple© library for the computations of the equivariant degree, was developed by A. Biglands.

6. Symmetric Hopf bifurcation for FDEs

In this section, we apply the equivariant degree method to study the Hopf bifurcation problem in systems of symmetric functional differential equations. Since in this case, the equivariant degree setting is completely parallel to the one that was developed for ordinary differential equations, we only point out the differences that are specific for FDEs and NFDEs. In order to simplify the exposition, we restrict ourselves to Γ being a finite group. In particular, in this case the set $\Phi_1^t(G)$ coincides with $\{(H) \in \mathcal{O}(G)\colon \dim W(H) = 1\}$. We also study a continuation of a symmetric branch of non-constant periodic solutions for FDEs.

Throughout this section V stands for an orthogonal Γ-representation (Γ is finite).

6.1. *Symmetric Hopf bifurcation for FDEs with delay: General framework*

Statement of the problem Given a constant $\tau \geqslant 0$, denote by $C_{V,\tau}$ the Banach space of continuous functions from $[-\tau, 0]$ to V equipped with the usual supremum norm

$$\|\varphi\| := \sup_{-\tau \leqslant \theta \leqslant 0} \bigl|\varphi(\theta)\bigr|, \quad \varphi \in C_{V,\tau}.$$

Given a continuous function $x : \mathbb{R} \to V$ and $t \in \mathbb{R}$, define $x_t \in C_{V,\tau}$ by

$$x_t(\theta) = x(t + \theta), \quad \theta \in [-\tau, 0].$$

Clearly, the Γ-action on V induces a natural isometric Banach representation of Γ on the space $C_{V,\tau}$ with the Γ-action given by

$$(\gamma\varphi)(\theta) := \gamma\bigl(\varphi(\theta)\bigr), \quad \gamma \in \Gamma,\ \theta \in [-\tau, 0].$$

Consider the following one-parameter family of differential delayed equations

$$\dot{x} = f(\alpha, x_t), \tag{140}$$

where $x : \mathbb{R} \to V$ is a differentiable function and $f : \mathbb{R} \oplus C_{V,\tau} \to V$ satisfies the following assumptions:

(A1) f is continuously differentiable;

(A2) f is Γ-equivariant, i.e.

$$f(\alpha, \gamma\varphi) = \gamma f(\alpha, \varphi), \quad \varphi \in C_{V,\tau},\ \alpha \in \mathbb{R},\ \gamma \in \Gamma;$$

(A3) $f(\alpha, 0) = 0$ for all $\alpha \in \mathbb{R}$.

For any $x_o \in V$, we use the same symbol to denote the constant function $x_o(t) \equiv x_o$. Clearly, $(x_o)_t = x_o$ for all $t \in \mathbb{R}$. A point $(\alpha, x_o) \in \mathbb{R} \oplus V$ is said to be a *stationary point* of (140) if $f(\alpha, x_o) = 0$. In particular, by condition (A3), $(\alpha, 0)$ is a stationary point of (140) for all $\alpha \in \mathbb{R}$. Moreover, we say that a stationary point (α, x_o) is *nonsingular* if the restriction of f to the space $\mathbb{R} \oplus V \subset \mathbb{R} \oplus C_{V,\tau}$, still denoted by f, has the derivative $D_x f(\alpha, x_o) : V \to V$ (with respect to $x \in V$), which is an isomorphism. The definition of the Hopf bifurcation for the system (140) occurring at $(\alpha_o, 0)$ is exactly the same as the one given in Subsection 4.1.

In what follows, we consider a fixed stationary point $(\alpha_o, 0)$ of (140). In order to prevent the occurrence of a steady-state bifurcation at $(\alpha_o, 0)$, we assume

(A4) The stationary point $(\alpha_o, 0)$ of (140) is non-singular, i.e.

$$\det\bigl(D_x f(\alpha_o, 0)|_V\bigr) \neq 0.$$

Characteristic equation Let V^c be the complexification of the vector space V and let the Γ-isotypical decompositions of V and V^c be given by (113), where $V_0 = V^\Gamma$, V_j is modeled on the real irreducible Γ-representation $\mathcal{V}_j$, $U_0 = (V^c)^\Gamma$ and U_j is modeled on the complex irreducible Γ-representation $\mathcal{U}_j$.

Let (α, x_o) be a stationary point of (140). The linearization of (140) at (α, x_o) leads to the following *characteristic equation* for the stationary point (α, x_o)

$$\det\nolimits_{\mathbb{C}} \Delta_{(\alpha,x_o)}(\lambda) = 0, \tag{141}$$

where

$$\Delta_{(\alpha,x_o)}(\lambda) := \lambda \,\mathrm{Id} - D_x f(\alpha, x_o)(\mathrm{e}^{\lambda\cdot}\cdot)$$

is a complex linear operator from V^c to V^c, with $(\mathrm{e}^{\lambda\cdot}\cdot)(\theta, x) = \mathrm{e}^{\lambda\theta} x$ and $D_x f(\alpha, x_o)(z \otimes x) = z \otimes D_x f(\alpha, x_o)x$ for $z \otimes x \in V^c$ (cf. [145]). Put $\Delta_\alpha(\lambda) := \Delta_{(\alpha,0)}(\lambda)$.

A solution λ_o to (141) is called a *characteristic root* of (141) at the stationary point (α, x_o). It is clear that (α, x_o) is a non-singular stationary point if and only if 0 is not a characteristic root of (141) at the stationary point (α, x_o).

Recall (see Definition 4.2) that a non-singular stationary point (α, x_o) is called a *center* if (141) permits a purely imaginary root. We call (α, x_o) an *isolated center* if it is the only center in some neighborhood of (α, x_o) in $\mathbb{R} \oplus V$.

By (A2) and (A3), the operator $\Delta_\alpha(\lambda)\colon V^c \to V^c$, $\alpha \in \mathbb{R}$, $\lambda \in \mathbb{C}$, is Γ-equivariant. Consequently, for every isotypical component U_j of V^c, $j = 0, 1, \ldots, s$ (cf. (113)), $\Delta_\alpha(\lambda)(U_j) \subseteq U_j$. Put

$$\Delta_{\alpha,j}(\lambda) := \Delta_\alpha(\lambda)|_{U_j}.$$

Crossing numbers Assume the following condition to be satisfied:

(A5) The stationary point $(\alpha_o, 0)$ is an isolated center for the system (140) such that (141) permits a purely imaginary root $\lambda = \mathrm{i}\beta_o$ with $\beta_o > 0$.

Let λ be a complex root of the characteristic equation $\det_{\mathbb{C}} \Delta_{\alpha_o}(\lambda) = 0$. We use the following notations:

$$E(\lambda) := \ker \Delta_{\alpha_o}(\lambda) \subset V^c,$$

$$E_j(\lambda) := E(\lambda) \cap U_j,$$

$$m_j(\lambda) := \dim_{\mathbb{C}} E_j(\lambda) / \dim_{\mathbb{C}} \mathcal{U}_j.$$

The integer $m_j(\lambda)$ is called the *$\mathcal{U}_j$-multiplicity* of the characteristic root λ.

Define S by formula (110). Under the assumption (A5), the constants $\delta > 0$ and $\varepsilon > 0$ can be chosen so small that the following condition is satisfied:

(*) For every $\alpha \in [\alpha_o - \varepsilon, \alpha_o + \varepsilon]$, if there is a characteristic root $u + \mathrm{i}v \in \partial S$ at $(\alpha, 0)$, then $u + \mathrm{i}v = \mathrm{i}\beta_o$ and $\alpha = \alpha_o$.

Put $\alpha_\pm := \alpha_o \pm \varepsilon$. Note that $\Delta_\alpha(\lambda)$ is analytic in $\lambda \in \mathbb{C}$ and continuous in $\alpha \in [\alpha_-, \alpha_+]$ (see [71]). It follows that $\det_{\mathbb{C}} \Delta_{\alpha_o \pm \varepsilon}(\lambda) \neq 0$ for all $\lambda \in \partial S$. So, the following notation (cf. (123))

$$\mathfrak{t}^{\pm}_{j,1}(\alpha_o, \beta_o) := \deg\big(\det_{\mathbb{C}} \Delta^{\mathbb{C}}_{\alpha_\pm, j}(\cdot), S\big), \tag{142}$$

is well-defined for $0 \leqslant j \leqslant s$ (see (113)).

Following the same lines as in Subsection 5.3 (see Definition 5.8), introduce

DEFINITION 6.1. Let $\mathcal{U}_j$ be a complex Γ-irreducible representation and $\mathcal{V}_{j,l} := {}^l\mathcal{U}_j$ for $l \in \mathbb{N}$. Put

$$\mathfrak{t}_{j,1}(\alpha_o, \beta_o) := \mathfrak{t}^{-}_{j,1}(\alpha_o, \beta_o) - \mathfrak{t}^{+}_{j,1}(\alpha_o, \beta_o), \tag{143}$$

and for any integer $l > 1$,

$$\mathfrak{t}_{j,l}(\alpha_o, \beta_o) := \mathfrak{t}_{j,1}(\alpha_o, l\beta_o). \tag{144}$$

Then, $\mathfrak{t}_{j,l}(\alpha_o, \beta_o)$ is called the *$\mathcal{V}_{j,l}$-isotypical crossing number* of $(\alpha_o, 0)$ corresponding to the characteristic root $\mathrm{i}\beta_o$.

REMARK 6.2. Observe that $\mathfrak{t}_{j,l}(\alpha_o, \beta_o) = 0$ if $\mathrm{i}l\beta_o$ is not a root of (141) (cf. (142) and (143)).

In order to establish the existence of small amplitude periodic solutions bifurcating from the stationary point $(\alpha_o, 0)$, i.e. the occurrence of Hopf bifurcation at the stationary point $(\alpha_o, 0)$, and to associate with $(\alpha_o, 0)$ a *local bifurcation invariant*, we apply the standard steps for the degree-theoretical approach.

Normalization of the period Normalization of the period is obtained by making the change of variable $u(t) = x(\frac{p}{2\pi}t)$ for $t \in \mathbb{R}$. We obtain the following equation, which is equivalent to (140):

$$\dot{u}(t) = \frac{p}{2\pi} f(\alpha, u_{t,2\pi/p}), \tag{145}$$

where $u_{t,2\pi/p} \in C_{V,\tau}$ is defined by

$$u_{t,2\pi/p}(\theta) = u\left(t + \frac{2\pi}{p}\theta\right), \quad \theta \in [-\tau, 0].$$

Evidently, $u(t)$ is a 2π-periodic solution of (145) if and only if $x(t)$ is a p-periodic solution of (140). We can also introduce $\beta := \frac{2\pi}{p}$ into Eq. (145) to obtain

$$\dot{u}(t) = \frac{1}{\beta} f(\alpha, u_{t,\beta}). \tag{146}$$

$\Gamma \times S^1$-equivariant setting in functional spaces We use the standard identification $S^1 = \mathbb{R}/2\pi\mathbb{Z}$ (with $t \leftrightarrow e^{it}$) and the operators L, j, K defined by (81), (82) and (85). Put $\mathbb{R}^2_+ := \mathbb{R} \times \mathbb{R}_+$. Take $(L+K)^{-1} : L^2(S^1; V) \to H^1(S^1; V)$ (cf. Subsection 4.2). It can be easily shown that the map $\mathcal{F} : \mathbb{R}^2_+ \times H^1(S^1; V) \to H^1(S^1; V)$ defined by

$$\mathcal{F}(\alpha, \beta, u) = (L+K)^{-1}\left[Ku + \frac{1}{\beta} N_f\big(\alpha, \beta, j(u)\big)\right], \tag{147}$$

is completely continuous, where $N_f : \mathbb{R}^2_+ \times C(S^1; V) \to L^2(S^1; V)$ is defined by

$$N_f(\alpha, \beta, v)(t) = f(\alpha, v_{t,\beta}), \tag{148}$$

and $e^{it} \in S^1$, $(\alpha, \beta, v) \in \mathbb{R}^2_+ \times C(S^1; V)$.

REMARK 6.3. Notice that, because of the presence of the delay in (140), the map N_f depends on the parameter β, which is the only difference from the setting that was discussed in Subsection 4.2.

Put $W := H^1(S^1; V)$. The space W is an isometric Hilbert $\Gamma \times S^1$-representation of the group $G = \Gamma \times S^1$ (see Subsection 5.1) and the non-linear operator $\mathcal{F}$, defined by (147), is clearly G-equivariant.

REMARK 6.4. Notice that $(\alpha, \beta, u) \in \mathbb{R}^2_+ \times W$ is a 2π-periodic solution of (146) if and only if $u = \mathcal{F}(\alpha, \beta, u)$. Consequently, the occurrence of a Hopf bifurcation at $(\alpha_o, 0)$ for Eq. (140) is equivalent to a bifurcation of 2π-periodic solutions of (146) from $(\alpha_o, \beta_o, 0)$ for some $\beta_o > 0$. On the other hand, if a bifurcation at $(\alpha_o, \beta_o, 0) \in \mathbb{R}^2_+ \times W$ takes place in (146), then we *necessarily* have that the operator $\mathrm{Id} - D_u\mathcal{F}(\alpha_o, \beta_o, 0) : W \to W$ is not an isomorphism, or equivalently, $il\beta_o$ is a purely imaginary characteristic root at $(\alpha_o, 0)$, for some $l \in \mathbb{N}$, i.e. $\det_{\mathbb{C}} \Delta_{\alpha_o}(il\beta_o) = 0$.

Sufficient condition for Hopf bifurcation Bearing in mind Remarks 6.3 and 6.4 and literally follow Subsection 5.1 (see also Subsection 4.3), one can establish

THEOREM 6.5. *Given the system* (140), *assume conditions* (A1)–(A5) *to be satisfied. Take* $\mathcal{F}$ *defined by* (147) *and construct* Ω *according to* (93). *Let* $\varsigma : \overline{\Omega} \to \mathbb{R}$ *be a* G*-invariant auxiliary function* (*see Definition* 4.3) *and let* $\mathfrak{F}_\varsigma$ *be defined by* (94). *Then, a complete analogue of the conclusion of Theorem* 5.4 *is true for the systems* (140) *and* (146).

REMARK 6.6. Following the scheme described in Subsections 5.2 and 5.3, one can establish a complete analogue of formula (134) in the setting relevant to Theorem 6.5.

6.2. *Symmetric Hopf bifurcation for neutral FDEs*

Statement of the problem We use the same notations as in Subsection 6.1.

Consider the following one-parameter family of *neutral equations*:

$$\frac{\mathrm{d}}{\mathrm{d}t}\big[x(t) - b(\alpha, x_t)\big] = f(\alpha, x_t), \tag{149}$$

where $x : \mathbb{R} \to V$ is a continuous function,[2] and $b, f : \mathbb{R} \oplus C_{V,\tau} \to V$ satisfy the following assumptions:

(A1) b, f are continuously differentiable;

(A2) b, f are Γ-equivariant;

(A3) $b(\alpha, 0) = 0$, $f(\alpha, 0) = 0$ for all $\alpha \in \mathbb{R}$.

Also, to prevent the occurrence of the steady-state bifurcation, assume

(A4) $\det(D_x f(\alpha, 0)|_V) \neq 0$ for all $\alpha \in \mathbb{R}$.

In addition, assume that

(L) b satisfies the Lipschitz condition with respect to the second variable, i.e.

$$\exists_\kappa \ 0 \leqslant \kappa < 1, \ \text{s.t.} \ \big\|b(\alpha, \varphi) - b(\alpha, \psi)\big\| \leqslant \kappa \|\varphi - \psi\|_\infty \tag{150}$$

for all $\varphi, \psi \in C_{V,\tau}$, $\alpha \in \mathbb{R}$.

Literally following Section 6.1, one can define the notions of stationary/singular points to (149).

Characteristic equation Let (α, x_o) be a stationary point of (149). The linearization of (149) at (α, x_o) leads to the following *characteristic equation*,

$$\det_{\mathbb{C}} \Delta_{(\alpha, x_o)}(\lambda) = 0, \tag{151}$$

where

$$\Delta_{(\alpha, x_o)}(\lambda) := \lambda\big[\mathrm{Id} - D_x b(\alpha, x_o)(\mathrm{e}^{\lambda \cdot} \cdot)\big] - D_x f(\alpha, x_o)(\mathrm{e}^{\lambda \cdot} \cdot). \tag{152}$$

In what follows, assume that

(A5) The system (149) has an isolated center $(\alpha_o, 0)$ for some $\alpha_o \in \mathbb{R}$, with the corresponding purely imaginary characteristic root $\mathrm{i}\beta_o$, for $\beta_o > 0$.

We associate to the problem (149) the *local bifurcation invariant* and follow the standard steps (similar to those in Section 6.1) of the degree-theoretical treatment of the Hopf bifurcation phenomenon.

Normalization of period By making a change of variable $x(t) = u(\beta t)$ with $\beta := \frac{2\pi}{p}$, we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\big[u(t) - b(\alpha, u_{t,\beta})\big] = \frac{1}{\beta} f(\alpha, u_{t,\beta}), \tag{153}$$

---

[2] Formally speaking, we do not require in (149) that $x(t)$ is differentiable, but only $x(t) - b(\alpha, x_t)$ to be continuously differentiable.

where $u_{t,\beta} \in C_{V,\tau}$ is defined by

$$u_{t,\beta}(\theta) = u(t + \beta\theta), \quad \theta \in [-\tau, 0].$$

Evidently, $u(t)$ is a 2π-periodic solution of (153) if and only if $x(t)$ is p-periodic solution of (149).

$\Gamma \times S^1$-equivariant setting in functional spaces Put $W := H^1(S^1; V)$ and let L, j, K and N_f be defined by (81), (82), (85) and (148) respectively. Define $N_b : \mathbb{R}^2_+ \times C(S^1; V) \to L^2(S^1; V)$ by

$$N_b(\alpha, \beta, v)(t) = b(\alpha, v_{t,\beta}).$$

Take $(L + K)^{-1} : L^2(S^1; V) \to W$ and the map $\mathcal{F} : \mathbb{R}^2_+ \times W \to W$ defined by

$$\begin{aligned} \mathcal{F}(\alpha, \beta, u) = {} & (L + K)^{-1}\left[\frac{1}{\beta} N_f(\alpha, \beta, u) + K\big(u - N_b(\alpha, \beta, u)\big)\right] \\ & + N_b(\alpha, \beta, u). \end{aligned} \tag{154}$$

Observe that the map $\mathcal{F}$ is a sum of two maps, where the first map

$$(\alpha, \beta, u) \mapsto (L + K)^{-1}\left[\frac{1}{\beta} N_f(\alpha, \beta, u) + K\big(u - N_b(\alpha, \beta, u)\big)\right],$$

is completely continuous, and the second map $(\alpha, \beta, u) \mapsto N_b(\alpha, \beta, u)$ is a Banach contraction with constant κ ($0 \leqslant \kappa < 1$) (see assumptions (A1) and (L)). Therefore, $\mathcal{F}$ is a condensing map (see Definition 3.54 and Remark 3.55).

Finally, an analogue of Remark 6.4 is applied to Eq. (149).

Sufficient condition for Hopf bifurcation Following the same lines as in Subsections 4.3 and 6.1, define Ω and $\mathfrak{F}_\varsigma$ by (93) and (94) respectively. Obviously, $\mathfrak{F}_\varsigma$ is an Ω-admissible G-equivariant condensing field. Therefore, the standard Nussbaum–Sadovskii extension of the twisted degree (see Definition 3.57, Lemma 3.59 and formula (70)) can be applied to the admissible pair $(\mathfrak{F}_\varsigma, \Omega)$. In a standard way, one can easily establish

THEOREM 6.7. *Given the system* (149), *assume conditions* (A1)–(A5) *and* (L) *to be satisfied. Take $\mathcal{F}$ defined by* (154) *and construct Ω according to* (93). *Let $\varsigma : \overline{\Omega} \to \mathbb{R}$ be a G-invariant auxiliary function* (*see Definition* 4.3) *and let $\mathfrak{F}_\varsigma$ be defined by* (94). *Then, a complete analogue of the conclusion of Theorem* 5.4 *is true for the systems* (149) *and* (153). *In addition, an analogue of Remark* 6.6 *is valid.*

6.3. *Global bifurcation problems*

In this subsection, we apply the twisted degree method to a global Hopf bifurcation problem for a system of symmetric functional differential equations to analyze a continuation of symmetric branches of non-constant periodic solutions. To this end, we translate/adapt conditions (A1)–(A5) from Subsection 6.1 to the abstract setting related to symmetric global Hopf bifurcation occurring in the system (140).

To begin with, assume that the system (140) satisfies conditions (A1)–(A3). Take the Hilbert G-representation $W := H^1(S^1; V)$ and define $\mathcal{F}: \mathbb{R}^2 \oplus W \to W$ by formula (147). Put $\mathfrak{F}(\alpha, \beta, u) := u - \mathcal{F}(\alpha, \beta, u)$. Then, the conditions (A1)–(A3) translate as:

(F1) $\mathfrak{F}$ is a completely continuous G-equivariant field of class C^1 and $\mathfrak{F}(\lambda, 0) = 0$ for all $(\lambda, 0) \in \mathbb{R}^2 \oplus W$.

Put $\bar{\mathfrak{F}} := \mathfrak{F}|_{\mathbb{R}^2 \oplus W^{S^1}} : \mathbb{R}^2 \oplus W^{S^1} \to W^{S^1}$. Then, the condition (A4) translates as:

(F2) $D_w\bar{\mathfrak{F}}(\lambda, 0)$ is an isomorphism from W^{S^1} to W^{S^1} for all $\lambda \in \mathbb{R}^2$.

Condition (A5), being necessary for the occurrence of the (local) Hopf bifurcation (cf. Proposition 4.1), translates as: $D_w\mathfrak{F}(\lambda_o, 0): W \to W$ is not an isomorphism. To study the *global* behavior of branches bifurcating from $(\lambda_o, 0)$, we need the following condition to be satisfied:

(F3) The set $\Lambda := \{\lambda \in \mathbb{R}^2\colon\ D_w\mathfrak{F}(\lambda, 0): W \to W$ is not an isomorphism$\}$ is discrete in $\mathbb{R}^2$.

We are interested in a solution set to the equation

$$\mathfrak{F}(\lambda, w) = 0, \quad (\lambda, w) \in \mathbb{R}^2 \oplus W. \tag{155}$$

In the same way, as it was done in Subsection 4.3, one can define trivial/nontrivial solutions to (155) as well as its bifurcation points. Bearing in mind condition (F3), for each $\lambda_o \in \Lambda$, one can associate the local bifurcation invariant $\omega(\lambda_o)$ (cf. Section 6.1) and the *local bifurcation Theorem 6.5* can be applied.

Below we discuss the global bifurcation phenomenon for Eq. (155). Let $\mathcal{S}$ be the closure of the set of all non-trivial solutions to (155), i.e.

$$\mathcal{S} := \overline{\bigl\{(\lambda, w) \in \mathbb{R}^2 \oplus W\colon\ \mathfrak{F}(\lambda, w) = 0, w \neq 0\bigr\}}. \tag{156}$$

Notice that $(\lambda_o, 0)$ is a bifurcation point of (155) if and only if $(\lambda_o, 0) \in \mathcal{S}$. Take a connected component $\mathcal{C} \subset \mathcal{S}$. If $\mathcal{C}$ contains a bifurcation point $(\lambda_o, 0)$, then it is clearly G-invariant. Notice that, in general, $\mathcal{C}$ may be composed of several orbit types, i.e.

$$\mathcal{C} = \bigcup_{(H)} \mathcal{C}_{(H)},$$

and the global behavior of $\mathcal{C}_{(H)}$ can be different for different orbit types (H), for example some of the branches $\mathcal{C}_{(H)}$ may be bounded, while the other are unbounded.

The result following below can be considered as a *global Hopf bifurcation theorem* for the system (140).

THEOREM 6.8. *Suppose that* $\mathfrak{F}: \mathbb{R}^2 \oplus W \to W$ *satisfies the assumptions* (F1)–(F3) *and let* $\mathcal{C}$ *be a bounded connected component of* $\mathcal{S}$ (*cf.* (156)) *such that* $\mathcal{C} \cap \mathbb{R}^2 \times \{0\} \neq \emptyset$. *Then,*

$$\mathcal{C} \cap \mathbb{R}^2 \times \{0\} = \bigl\{(\lambda_1, 0), (\lambda_2, 0), \dots, (\lambda_N, 0)\bigr\},$$

and

$$\sum_{k=1}^{N} \omega(\lambda_k) = 0.$$

The proof of Theorem 6.8 can be easily obtained by combining the methods developed to prove Theorems 4.4, 5.4 and 6.5 with the standard global bifurcation techniques (see, for instance, [89,93,95,128]).

In order to present global bifurcation results for symmetric systems we will be dealing with in what follows, we need a slightly more general

THEOREM 6.9. *Suppose that* $\mathfrak{F}: \mathbb{R}^2 \oplus W \to W$ *satisfies the assumptions* (F1)–(F3) *and let* $\mathcal{C}^{(H_o)}$ *be a bounded connected component of* $\mathcal{S}^{(H_o)}$ (*cf.* (156)) *such that* $\mathcal{C}^{(H_o)} \cap \mathbb{R}^2 \times \{0\} = \{(\lambda_1, 0), (\lambda_2, 0), \dots, (\lambda_N, 0)\} \neq \emptyset$. *Suppose that*

$$\omega(\lambda_k) = \sum_{(H)} n_H^k(H).$$

Then,

$$\sum_{k=1}^{N} n_{H_o}^k = 0.$$

PROOF. Consider the map

$$\mathfrak{F}^{H_o}: \mathbb{R}^2 \oplus W^{H_o} \to W^{H_o}.$$

Put $G_o = N(H_o)$. Since the map $\mathfrak{F}^{H_o}$ is G_o-equivariant and satisfies similar to (F1)–(F3) conditions, we can define for every $\lambda_o \in \Lambda$ the local bifurcation invariant

$$\omega_o(\lambda_o) = \sum_{(K)} m_K(K) \in A_1^t(G_o)$$

associated with $\mathfrak{F}^{H_o}$. Since $\mathcal{C}^{H_o}$ is a bounded connected component of $\mathcal{S}^{H_o}$, we can apply Theorem 6.8 to obtain

$$\sum_{k=1}^{N} \omega_o(\lambda_k) = 0, \quad \omega_o(\lambda_k) = \sum_{K} m_K^k(K).$$

On the other hand, (H_o) is an orbit type in W^{H_o} and, it is easy to see that $m_{H_o}^k = n_{H_o}^k$ for all $k = 1, 2, \dots, N$. Consequently,

$$\sum_{k=1}^{N} n_{H_o}^k = 0,$$

and the statement follows. □

COROLLARY 6.10. *Suppose as in Theorem* 6.9 that $\mathfrak{F}:\mathbb{R}^2 \oplus W \to W$ *satisfies the assumptions* (F1)–(F3) *and let* $\mathcal{C}^{(H_o)}$ *be a connected component of* $\mathcal{S}^{(H_o)}$ (*cf.* (156)) *such that* $\mathcal{C}^{(H_o)} \cap \mathbb{R}^2 \times \{0\} = \{(\lambda_1, 0)\}$, *where* (H_o) *is an orbit type in* W. *If* $n^1_{H_o} \neq 0$, *then* $\mathcal{C}^{(H_o)}$ *is unbounded.*

REMARK 6.11.

(i) Observe that the conclusions of Theorems 6.8 and 6.9 and Corollary 6.10 are still true if we replace condition (F2) with the following one:

  (F2′) (a) $D_w\bar{\mathfrak{F}}(\lambda, 0)$ is an isomorphism from W^{S^1} to W^{S^1} for all $\lambda = (\alpha, \beta) \neq (\alpha_o, \beta)$, where α_o is a certain fixed number;

  (b) there is no Hopf bifurcation in (140) from the point $(\alpha_o, 0)$.

(ii) It should be pointed out that the global bifurcation results described in this subsection can be easily extended to almost all the classes of parametrized symmetric dynamical systems considered in this paper (as long as the corresponding local result is established).

6.4. *Bibliographical remarks*

The approach outlined in Section 6.1 (resp. Section 6.2) was discussed in [11] (resp. [15]) (see also [19]). The global bifurcation results given in Section 6.3 were published in [13]. Similar systems of symmetric DEs and FDEs were considered in [67,65,66,68,92,94,95, 129,140,145,146,148]. For the singularity theory treatment of the symmetric Hopf bifurcation in NFDEs, we refer to [69]. In the non-symmetric case, local and global Hopf bifurcation problems in FDEs were studied in [36,110,111,124,125,122,123].

7. Symmetric Hopf bifurcation problems for functional parabolic systems of equations

As we have seen in Sections 4–6, the twisted degree provides an effective and direct method for the classification of symmetric Hopf bifurcations in ODEs and FDEs, based on the equivariant spectral properties of the linearized equation at a stationary point. In this section, we present a setting for applications of the twisted degree to study the Hopf bifurcation problem for a continuously parametrized Γ-symmetric Fredholm coincidence equation, which is next associated to a system of non-linear functional parabolic equations with Γ-symmetries.

7.1. *Symmetric bifurcation in parameterized equivariant coincidence problems*

Delayed functional parabolic systems of our interest fall into a category of the so-called equivariant *coincidence* problems. Therefore, we start with a brief discussion of an abstract functional setting for such equivariant coincidence problems. We use the notations introduced in Subsections 2.3 and 2.4 ($G = \Gamma \times S^1$).

Functional setting for equivariant coincidence problems Let $\mathbb{E}$ and $\mathbb{F}$ be real isometric Banach G-representations, $\mathcal{P}$ a topological space equipped with the trivial G-action, and $\{L_\lambda\}_{\lambda\in\mathcal{P}} \subset \mathrm{Op}^G$ a *continuous family of equivariant Fredholm operators of index zero, parametrized by* $\mathcal{P}$, i.e. $L_\lambda \in \mathfrak{F}_0^G$ for each $\lambda \in \mathcal{P}$, and the mapping $\eta : \mathcal{P} \to \mathrm{Op}^G$ defined by $\eta(\lambda) = L_\lambda$ for $\lambda \in \mathcal{P}$, is continuous.

Define ξ by

$$\xi := \big\{(\lambda, u, y) \in \mathcal{P} \times (\mathbb{E} \oplus \mathbb{F})\colon\ u \in \mathrm{Dom}(L_\lambda),\ \ y = L_\lambda u\big\},$$

and consider $\pi : \xi \to \mathcal{P}$, $\pi(\lambda, u, y) = \lambda$ for $(\lambda, u, y) \in \xi$. It has been shown in [50] that $\pi : \xi \to \mathcal{P}$ determines a locally trivial G-vector bundle.

Let

$$\mathcal{E} := \big\{(\lambda, u) \in \mathcal{P} \times \mathbb{E}\colon\ u \in \mathbb{E}_{L_\lambda}\big\} \tag{157}$$

and let $p_1 : \xi \to \mathcal{E}$ be given by $p_1(\lambda, u, y) = (\lambda, u)$, for $(\lambda, u, y) \in \xi$. Since, for every $\lambda \in \mathcal{P}$, the projection $pr_1 : \mathrm{Gr}(L_\lambda) \to \mathbb{E}_\lambda := \mathbb{E}_{L_\lambda}$ is an equivariant isometry, the mapping $p_1 : \xi \to \mathcal{E}$ gives us the natural identification of the G-bundles ξ and $\mathcal{E}$ (we use the same symbol for a bundle and its total space).

Define the vector bundle morphism $L : \mathcal{E} \to \mathbb{F}$, where $\mathbb{F}$ is viewed as a bundle over a one-point space, by

$$L(\lambda, u) = L_\lambda u, \quad (\lambda, u) \in \mathcal{E}. \tag{158}$$

DEFINITION 7.1. Let X be a subset of $\mathcal{P}$ and let L be given by (157) and (158). An *equivariant resolvent* of L over X is a G-vector bundle morphism $K : X \times \mathbb{E} \to \mathbb{F}$ such that

(i) for every $\lambda \in X$, $K_\lambda : \mathbb{E} \to \mathbb{F}$ is a finite-dimensional linear operator;
(ii) for every $\lambda \in X$, $L_\lambda + K_\lambda : \mathbb{E}_\lambda \to \mathbb{F}$ is an isomorphism.

Denote by $\mathcal{R}^G(L, X)$ the set of all equivariant resolvents of L over X.

REMARK 7.2.

(i) In contrast to the non-equivariant case, given $\lambda_o \in \mathcal{P}$, one may have $\mathcal{R}^G(L, \{\lambda_o\}) = \emptyset$.
(ii) Also, in general it might happen that $\mathcal{R}^G(L, X) = \emptyset$, while $\mathcal{R}^G(L, \{\lambda_o\}) \neq \emptyset$ for each $\lambda_o \in X$.

In the light of Remark 7.2, the following result turns out to be useful.

LEMMA 7.3. (Cf. [90].) *Let $X \subset \mathcal{P}$ be a compact contractible set containing a point λ^* such that $\mathcal{R}^G(L, \{\lambda^*\}) \neq \emptyset$. Then, $\mathcal{R}^G(L, X) \neq \emptyset$.*

Assume the following condition to be satisfied:

(H1) There exists a compact subset $X \subset \mathcal{P}$ such that $\mathcal{R}^G(L, X) \neq \emptyset$.

Fix $K \in \mathcal{R}^G(L, X)$ and put

$$R_\lambda := (L_\lambda + K_\lambda)^{-1} \tag{159}$$

(cf. Definition 7.1(ii)).

Given a completely continuous G-equivariant map $F : \mathcal{E} \to \mathbb{F}$, consider the associated *parametrized equivariant coincidence problem* (cf. [90])

$$L_\lambda u = F(\lambda, u), \quad (\lambda, u) \in \mathcal{E}|_{X \times \mathrm{Dom}(L_\lambda)}. \tag{160}$$

Using the resolvent K, one can transform (160) into the following fixed-point problem:

$$y = \mathcal{F}(\lambda, y), \quad (\lambda, y) \in X \times \mathbb{F}, \tag{161}$$

where

$$\mathcal{F}(\lambda, y) = F(\lambda, R_\lambda y) + K_\lambda(R_\lambda y), \quad (\lambda, y) \in X \times \mathbb{F}.$$

By assumption (H1), X is compact, therefore, $\mathcal{F}$ is completely continuous.

Bifurcation invariant for the equivariant coincidence problem In what follows, $\mathbb{E}$, $\mathbb{F}$ stand for isometric Banach G-representations, $\mathcal{P} = \mathbb{R} \times \mathbb{R}_+$ and $\{L_\lambda\}_{\lambda \in \mathcal{P}}$ is a continuous family of G-equivariant Fredholm G-equivariant operators of index zero satisfying condition (H1). Fix $K \in \mathcal{R}^G(L, X)$ with R_λ, $\lambda \in \mathcal{P}$, defined by (159).

Keeping in mind the setting relevant to parametrized parabolic systems discussed in the next subsections, we will specify F from (160), assuming

(H2)
- (i) there exists a real isometric Banach G-representation $\widehat{\mathbb{E}}$ and an injective G-vector bundle morphism $J : \mathcal{E} \to \mathcal{P} \times \widehat{\mathbb{E}}$ such that $J_\lambda := J(\lambda, \cdot)$ is a compact linear operator for every $\lambda \in \mathcal{P}$;
- (ii) there exists an equivariant C^1-map $\widehat{F} : \mathcal{P} \times \widehat{E} \to \mathbb{F}$.

Put

$$F := \widehat{F} \circ J. \tag{162}$$

Obviously, F is G-equivariant and completely continuous.

Consider now the coincidence problem (160) with F defined by (162) (see also condition (H2)). In addition, assume that there exists a two-dimensional submanifold $M \subset \mathcal{P} \times \mathbb{E}^G$ (thought of as a “bifurcation surface”) satisfying the following two conditions:

(H3) M is a subset of the solution set to (160);

(H4) if $(\lambda_o, u_o) \in M$, then there exist open neighborhoods U_{λ_o} of λ_o in $\mathcal{P}$ and U_{u_o} of u_o in $\mathbb{E}^G$, and a C^1-map $\chi : U_{\lambda_o} \to \mathbb{E}^G$ such that

$$M \cap (U_{\lambda_o} \times U_{u_o}) = \mathrm{Gr}(\chi).$$

Bearing in mind condition (H3), $(\lambda, u) \in M$ is called a *trivial solution* to (160) while the other solutions to (160) are said to be *non-trivial solutions*. A point $(\lambda_o, u_o) \in M$ is called a *bifurcation point* if in each neighborhood of (λ_o, u_o), there exists a nontrivial solution to (160). In what follows, we study the existence and multiplicity of branches of non-trivial solutions bifurcating from M, and classify their symmetries.

REMARK 7.4. (i) It is clear that (λ, u) is a solution to (160) if and only if (λ, y) is a solution to the system (161), where $y = (L_\lambda + K_\lambda)u$. Moreover, the set of all trivial solutions to (161) can be represented as

$$\widetilde{M} := \big\{(\lambda, y) \in X \times \mathbb{F}\colon \big(\lambda, R_\lambda(y)\big) \in M\big\}.$$

Then, condition (H4) translates as:

(H4′) if $(\lambda_o, y_o) \in \widetilde{M}$, then there exist open neighborhoods U_{λ_o} of λ_o in $\mathcal{P}$ and U_{y_o} of y_o in $\mathbb{F}^G$ and a C^1-map $\tilde{\chi} : U_{\lambda_o} \to \mathbb{F}^G$ such that

$$\widetilde{M} \cap (U_{\lambda_o} \times U_{y_o}) = \operatorname{Gr}(\tilde{\chi}).$$

(ii) Also, $(\lambda_o, u_o) \in M$ is a bifurcation point of (160) if and only if $(\lambda_o, y_o) \in \widetilde{M}$ is a bifurcation point of (161), where $y_o = (L_{\lambda_o} + K_{\lambda_o})u_o$.

Rewrite (161) as

$$(\pi - \mathcal{F})(\lambda, y) = 0, \quad (\lambda, y) \in X \times \mathbb{F}, \tag{163}$$

where π is the projection map on $\mathbb{F}$, $\pi(\lambda, y) = y$. Clearly, $\pi - \mathcal{F}$ is a G-equivariant completely continuous field of class C^1, and

$$D_y(\pi - \mathcal{F})(\lambda, y) = \operatorname{Id} - \big(D_u F\big(\lambda, R_\lambda(y)\big)R_\lambda + K_\lambda R_\lambda\big).$$

Thus, by assumption (H2) (see also (162)), $D_y(\pi - \mathcal{F})$ is a bounded Fredholm operator of index zero. Since G acts trivially on $X \times \mathbb{F}^G$, for $(\lambda, y) \in X \times \mathbb{F}^G$, $D_y(\pi - \mathcal{F})(\lambda, y)$ is G-equivariant (in particular, it is also G-equivariant for $(\lambda, y) \in \widetilde{M}$). By the implicit function theorem, a *necessary* condition for $(\lambda_o, y_o) \in \widetilde{M}$ to be a bifurcation point, is that the derivative $D_y(\pi - \mathcal{F})(\lambda_o, y_o)$ is not an isomorphism of $\mathbb{F}$. Such a point $(\lambda_o, y_o) \in \widetilde{M}$ is called L*-singular*. An L-singular point (λ_o, y_o) is said to be *isolated*, if it is the only L-singular point in some neighborhood of (λ_o, y_o) in $\widetilde{M}$.

Finally, assume that

(H5) there exists an isolated L-singular point $(\lambda_o, y_o) \in \widetilde{M}$.

In order to associate a local bifurcation invariant $\omega(\lambda_o, u_o) \in A_1^t(G)$ to (160), take a neighborhood $\mathcal{D}_{\lambda_o}$ of (λ_o, y_o) in $\widetilde{M}$ such that (i) (λ_o, y_o) is the only L-singular point in $\mathcal{D}_{\lambda_o}$ and (ii) $\overline{\mathcal{D}}_{\lambda_o} \subset \widetilde{M} \cap (U_{\lambda_o} \times U_{y_o})$ (see (H4′)).

Choose a small number $r > 0$, define

$$U(r) := \big\{(\lambda, y) \in \mathcal{P} \times \mathbb{F}\colon \big(\lambda, \tilde{\chi}(\lambda)\big) \in \mathcal{D}_{\lambda_o},\ \big\|y - \tilde{\chi}(\lambda)\big\| < r\big\}, \tag{164}$$

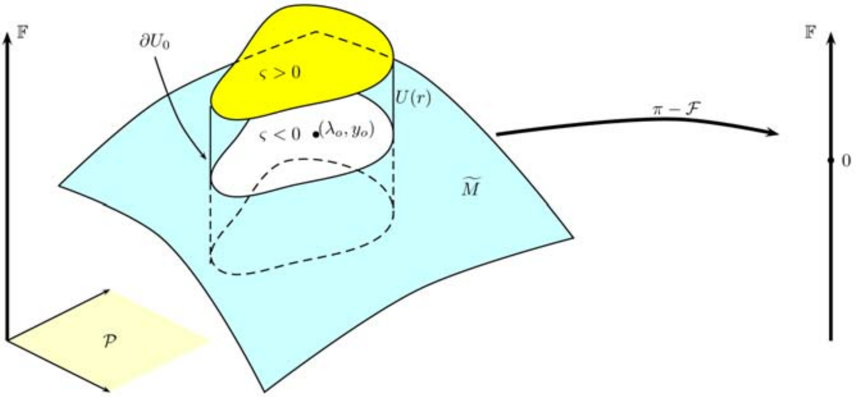

Fig. 5. Functional setting and auxiliary function for the bifurcation problem related to Eq. (163).

and introduce a G-invariant *auxiliary* function $\varsigma : \overline{U(r)} \to \mathbb{R}$ satisfying the properties

$$\begin{cases} \varsigma(\lambda, y) > 0 & \text{if } \|y - \tilde{\chi}(\lambda)\| = r, \\ \varsigma(\lambda, y) < 0 & \text{if } (\lambda, y) \in \mathcal{D}_{\lambda_o}. \end{cases} \tag{165}$$

Put

$$\partial U_0 := \big\{(\lambda, y) \in \overline{U(r)}\colon \big(\lambda, \tilde{\chi}(\lambda)\big) \in \partial \mathcal{D}_{\lambda_o}\big\} \subset \partial U(r).$$

Then, by the implicit function theorem, the above $r > 0$ can be chosen to be so small that

$$y - \mathcal{F}(\lambda, y) \neq 0, \quad \text{for } (\lambda, y) \in \partial U_0 \setminus \widetilde{M}$$

(see Fig. 5).

Define the map $\mathfrak{F}_\varsigma : \overline{U(r)} \to \mathbb{R} \oplus \mathbb{F}$ by

$$\mathfrak{F}_\varsigma(\lambda, y) := \big(\varsigma(\lambda, y), (\pi - \mathcal{F})(\lambda, y)\big), \tag{166}$$

which is clearly a $U(r)$-admissible G-equivariant completely continuous vector field. Therefore, the following *local bifurcation invariant*

$$\omega(\lambda_o, u_o) := G\text{-Deg}^t\big(\mathfrak{F}_\varsigma, U(r)\big) \in A_1^t(G) \tag{167}$$

is well-defined.

Using the standard scheme discussed in Sections 4–6, one can prove the following G-symmetric (local) bifurcation result for the equivariant coincidence problem (160).

THEOREM 7.5 (Local bifurcation theorem). *Suppose that the assumptions* (H1)–(H5) *are satisfied,* $\omega(\lambda_o, u_o)$ *is given by* (167) (*with* $\mathfrak{F}_\varsigma$ *defined by* (166), $U(r)$ *by* (164) *and* ς *satisfying* (165)). *If*

$$\omega(\lambda_o, u_o) = \sum_{(H)} n_H(H) \neq 0,$$

i.e., there is $n_{H_o} \neq 0$ *for some orbit type* (H_o), *then there exists a branch of non-trivial solutions* (λ, u) *to Eq.* (160) *bifurcating from* (λ_o, u_o) *such that* $G_u \supset H_o$.

7.2. *Hopf bifurcation for FPDEs with symmetries: Reduction to local bifurcation invariant*

Throughout this section, assume $\Gamma = \Gamma_1 \times \Gamma_2$, where Γ_1 and Γ_2 are compact Lie groups. Let $V' := \mathbb{R}^m$ (resp. $V := \mathbb{R}^n$) be an orthogonal Γ_1-representation (resp. Γ_2-representation). Assume that $\Omega \subset V'$ is an open Γ_1-invariant bounded set such that $\partial\Omega$ is C^2-smooth. Clearly, the space $L^2(\mathbb{R} \times \overline{\Omega}; V)$ is an isometric Banach Γ-representation with the Γ-action given by

$$(\gamma u)(t, x) = \gamma_2\big(u(t, \gamma_1 x)\big), \quad \gamma = (\gamma_1, \gamma_2) \in \Gamma_1 \times \Gamma_2.$$

Statement of the problem Consider a system of functional parabolic differential equations on $\mathbb{R} \times \overline{\Omega}$

$$\begin{cases} \frac{\partial}{\partial t} u(t, x) + P(\alpha, x)u = f(\alpha, u_t)(x), & (t, x) \in \mathbb{R} \times \Omega, \\ B(\alpha, x)u(t, x) = 0, & (t, x) \in \mathbb{R} \times \partial\Omega, \end{cases} \tag{168}$$

where $u \in L^2(\mathbb{R} \times \overline{\Omega}; V)$ satisfies appropriate differentiability requirements,[3] $u_t(\theta, x) := u(t + \theta, x)$ for $\theta \in [-\tau, 0]$ ($\tau > 0$ is a fixed constant), $\alpha \in \mathbb{R}$ is a (bifurcation) parameter, $f : \mathbb{R} \times C([-\tau, 0]; L^2(\Omega; V)) \to L^2(\Omega; V)$ is a map of class C^1, which is bounded on bounded sets, $P(\alpha, x) = [P_i(\alpha, x)]_{i=1}^n$ is a vector with components being second-order uniformly elliptic operators, i.e.

$$P_i(\alpha, x) = \nabla^T A_i(\alpha, x)\nabla + a_i(\alpha, x),$$

with $A_i(\alpha, x)$ being a continuously differentiable (with respect to α and x) $n \times n$ symmetric positive definite matrix satisfying the condition

$$\exists c_1, c_2 > 0\ \forall (\alpha, x) \in \mathbb{R} \times \overline{\Omega}\ \forall y \in V' \quad c_1\|y\| \leqslant y^T A_i(\alpha, x)y \leqslant c_2\|y\|,$$

---

[3] u is weakly differentiable with respect to t and has weak derivatives of order 2 with respect to $x \in \Omega$. More precisely, assume here that u is an element of the Sobolev space $H^{1,2}(\mathbb{R} \times \Omega; V)$ of L^2-integrable V-valued functions from $\mathbb{R} \times \Omega$ with weak L^2-integrable derivative in $\mathbb{R}$ and weak L^2-integrable derivatives of order 2 in Ω.

where ∇ stands for the gradient operator, and $a_i(\alpha, x)$ is continuous. The boundary operator $B(\alpha, x)$ is defined by either (Dirichlet conditions)

$$B(\alpha, x)u(t, x) = u(t, x)$$

or (mixed Dirichlet/Neumann conditions)

$$B(\alpha, x)u(t, x) = b(\alpha, x)u(t, x) + \frac{\partial}{\partial n}(\alpha, x)\, u(t, x),$$

where $b \in C^1(\mathbb{R} \times \partial\Omega; \mathbb{R})$, $\frac{\partial}{\partial n}(\alpha, x) = [\nu^T(x)A_i(\alpha, x)\nabla]_{i=1}^n$ ($\nu(x)$ is the outward normal vector to $\partial\Omega$ at x).

Assume that

(C1) the operators P, B and the map f are Γ-equivariant, i.e. for $\gamma \in \Gamma$,

$$\begin{aligned}
&\gamma P(\alpha, x)u = P(\alpha, x)\gamma u, && x \in \Omega,\ \theta \in [-\tau, 0],\\
&\gamma f\big(\alpha, v(\theta, x)\big) = f\big(\alpha, \gamma v(\theta, x)\big), && x \in \Omega,\ \theta \in [-\tau, 0],\\
&\gamma B(\alpha, x)u = B(\alpha, x)\gamma u, && x \in \partial\Omega.
\end{aligned}$$

We use the standard identification $S^1 \simeq \mathbb{R}/2\pi\mathbb{Z}$ and introduce the following notation

$$\mathcal{H}^{1,2}_{B(\alpha)} = \big\{\varphi \in H^{1,2}(S^1 \times \Omega; V):\ B(\alpha, x)\varphi = 0\big\}, \tag{169}$$

where $H^{k,\ell}(S^1 \times \Omega; V)$ stands for the Sobolev space of V-valued functions with weak (L^2-integrable) derivatives of order k in S^1 and of order l in Ω. Put

$$\mathbb{E} = \mathbb{F} = L^2(S^1 \times \Omega; V), \quad \mathcal{P} = \mathbb{R} \times \mathbb{R}_+, \quad \widehat{\mathbb{E}} = C\big(S^1; L^2(\Omega; V)\big), \tag{170}$$

where $\widehat{\mathbb{E}}$ is equipped with the usual supremum norm.

We are looking for p-periodic solutions to the system (168) for an unknown period $p > 0$.

Normalization of the period As usual, we replace the original problem with the equivalent one, for which we are looking for 2π-periodic solutions. Namely, let $\beta := \frac{2\pi}{p}$ and

$$v(t, x) = u\left(\frac{1}{\beta}t, x\right).$$

Then, the original problem is reduced to finding non-trivial solutions (α, β, v) for the system

$$\begin{cases}
\frac{\partial}{\partial t}v(t, x) + \frac{1}{\beta}P(\alpha, x)v = \frac{1}{\beta}f(\alpha, v_{t,\beta})(x), & (t, x) \in \mathbb{R} \times \Omega,\\
B(\alpha, x)v(t, x) = 0, & (t, x) \in \mathbb{R} \times \partial\Omega,\\
v(t, x) = v(t + 2\pi, x), & (t, x) \in \mathbb{R} \times \Omega,
\end{cases} \tag{171}$$

where

$$v_{t,\beta}(\theta,x) := v(t+\beta\theta,x) \quad \text{for } (\theta,x)\in[-\tau,0]\times\Omega.$$

$\Gamma\times S^1$*-setting in functional spaces* Below we reformulate the system (171) as an equivariant parametrized coincidence problem based on the general discussion in Subsection 7.1.

For every $\lambda := (\alpha,\beta)\in\mathcal{P}$, define the subspace

$$\operatorname{Dom}(L_\lambda) := \bigl\{u\in\mathbb{E}\colon\ u\in\mathcal{H}^{1,2}_{B(\alpha)}\bigr\},$$

and the operator

$$L_\lambda : \operatorname{Dom}(L_\lambda)\subset\mathbb{E}\to\mathbb{E}$$

(cf. (170)) by

$$L_\lambda v(t,x) := \frac{\partial}{\partial t}v(t,x) + \frac{1}{\beta}P(\alpha,x)v$$

(cf. (169)–(171)).

Notice that $\mathbb{E}$, $H^{1,2}(S^1\times\Omega;V)$ and $\widehat{\mathbb{E}}$ are isometric Banach G-representations, where S^1 acts in a standard way by shifting the time argument t. It is also clear (see [106]) that each (unbounded) linear operator L_λ, for $\lambda\in\mathcal{P}$, is a closed G-equivariant Fredholm operator of index zero, and the orthogonal projection on the (finite-dimensional) kernel of L_λ is a G-equivariant resolvent K of L_λ. Therefore, $R^G(L,\{\lambda\})\neq\emptyset$ for any $\lambda\in\mathcal{P}$, and, by Lemma 7.3, the condition (H1) is satisfied for every compact subset $X\subset\mathcal{P}$.

On the other hand, since

$$\frac{1}{\beta}f(\alpha,v_{t,\beta})\in L^2(\Omega;V) \quad \text{for } v_{t,\beta}\in C\bigl([-\tau,0];L^2(\Omega;V)\bigr),$$

we have the continuous map $N_f:\mathcal{P}\times\widehat{\mathbb{E}}\to L^2(\Omega,V)$ defined by

$$N_f(\alpha,\beta,v)(t) := \frac{1}{\beta}f(\alpha,v_{t,\beta}).$$

Define $\widehat{F}:\mathcal{P}\times\widehat{\mathbb{E}}\to\mathbb{F}$ by

$$\widehat{F}(\lambda,v)(t,x) := i\circ N_f(\alpha,\beta,v)(t)(x) = \frac{1}{\beta}f(\alpha,v_{t,\beta})(x), \quad \lambda=(\alpha,\beta),$$

where i denotes the natural embedding $\widehat{\mathbb{E}}\hookrightarrow\mathbb{F}$. The continuous differentiability of f implies that $\widehat{F}$ is continuously differentiable. Since the following composition of the embeddings

$$H^{1,2}(S^1\times\Omega;V)\hookrightarrow H^{2/3,0}(S^1\times\Omega;V)\hookrightarrow C\bigl(S^1;L^2(\Omega;V)\bigr)=\widehat{\mathbb{E}}$$

is compact (cf. [106]), we have the following embedding

$$J:\mathcal{E}\longrightarrow\mathcal{P}\times\widehat{\mathbb{E}}$$

where $J_\lambda:\mathbb{E}_\lambda\to\widehat{\mathbb{E}}$ is a compact operator for all $\lambda\in\mathcal{P}$. Therefore, $\widehat{F}$ and J satisfy the condition (H2) from Subsection 7.1. In particular, $F:\mathcal{E}\to\mathbb{F}$ defined by $F=\widehat{F}\circ J$ is a G-equivariant completely continuous map of class C^1.

As a consequence, finding a periodic solution $v\in H^{1,2}(S^1\times\Omega;V)$ for the system (171) is equivalent to solving the following parametrized coincidence problem (cf. (160))

$$L_\lambda v=F(\lambda,v),\qquad \lambda\in X,\tag{172}$$

where X is a given compact subset of $\mathcal{P}$.

Γ-symmetric steady-state solutions to (168) In order to describe a manifold of trivial solutions to (171) (cf. conditions (H3) and (H4) from Subsection 7.1), at which we expect the occurrence of a Hopf bifurcation, observe that the functions $u(t,x)$ from $H^{1,2}(S^1\times\Omega;V)$, constant with respect to the first variable, can be identified with functions from $H^2(\Omega;V)$, where $H^2(\Omega;V)$ denotes the Sobolev space of V-valued functions with weak (L^2-integrable) derivatives of order 2 in Ω. Clearly, for a function $u(t,x)$, constant with respect to t, we have $u_t(\theta,x)=u(\theta,x)$ for all $t\in\mathbb{R}$.

With these preliminaries on hands, introduce the following

DEFINITION 7.6. Let (α_o,u_o) be a solution to (168) satisfying the following conditions:

(i) $u_o\in H^2(\Omega,V)$;

(ii) $\gamma u_o=u_0$ for all $\gamma\in\Gamma$;

(iii) $\begin{cases}P(\alpha_o,x)u_o=f(\alpha_o,u_o)(x) & \text{in }\Omega,\\ B(\alpha_o,x)u_o=0 & \text{on }\partial\Omega.\end{cases}$

Then, (α_o,u_o) is called a Γ-*symmetric steady-state* solution to (168).

Introduce the following spaces

$$\begin{aligned}
\mathfrak{X}_{\alpha_o}&:=\big\{\omega\in H^2(\Omega;V):\ B(\alpha_o,x)\omega=0\big\},\\
\mathfrak{X}^c_{\alpha_o}&:=\big\{\omega\in H^2(\Omega;V^c):\ B(\alpha_o,x)\omega=0\big\},\\
\mathfrak{C}&:=C\big([-\tau,0];L^2(\Omega;V)\big),\\
\mathfrak{C}^c&:=C\big([-\tau,0];L^2(\Omega;V^c)\big),
\end{aligned}$$

where V^c stands for the complexification of the Γ-representation V. Identify $L^2(\Omega;V)$ with the subspace of $\mathfrak{C}$ consisting of constant $L^2(\Omega;V)$-valued functions, and $L^2(\Omega;V^c)$ with the subspace of $\mathfrak{C}^c$ consisting of constant $L^2(\Omega;V^c)$-valued functions. Denote by $\bar{f}(\alpha,\cdot)$ the restriction of $f(\alpha,\cdot)$ to $L^2(\Omega;V)$ and define

$$\mathcal{L}_{\alpha_o}:=P(\alpha_o,x)-\mathfrak{d}f_{\alpha_o}:\mathfrak{X}_{\alpha_o}\subset L^2(\Omega;V)\to L^2(\Omega;V),\tag{173}$$

where $\mathfrak{d}f_{\alpha_o}(\varphi):=D_u\bar{f}(\alpha_o,u_o)\varphi$ for $\varphi\in\mathfrak{X}_{\alpha_o}$.

In what follows, we apply the same symbols to denote the complexified operators $P(\alpha, x)$, $\mathfrak{d} f_\alpha$, and $B(\alpha_o, x)$, i.e. the operators:

$$\begin{aligned}
&P(\alpha, x) : \mathfrak{X}^c_\alpha \subseteq L^2(\Omega; V^c) \to L^2(\Omega; V^c),\\
&\mathfrak{d} f_\alpha : \mathfrak{C}^c \to L^2(\Omega; V^c),\\
&B(\alpha_o, x) : H^2(\Omega; V^c) \to L^2(\partial\Omega, V^c).
\end{aligned}$$

Suppose that (α_o, u_o) is a Γ-symmetric steady-state solution to (168) with $\alpha = \alpha_o$. We say that (α_o, u_o) is *non-singular* if $0 \notin \sigma(\mathcal{L}_{\alpha_o})$, where $\sigma(\mathcal{L}(\alpha_o))$ denotes the spectrum of $\mathcal{L}_{\alpha_o}$. Assume that

(C2) (α_o, u_o) is a nonsingular Γ-symmetric steady-state solution.

Then, by the implicit function theorem, there exists a continuously differentiable function $u(\alpha)$ for $\alpha \in (\alpha_o - \eta, \alpha_o + \eta)$ (for a sufficiently small $\eta > 0$) such that $(\alpha, u(\alpha))$ is a Γ-symmetric steady-state solution to (168) for each α (the condition $\gamma u(\alpha) = u(\alpha)$ for all $\gamma \in \Gamma$ (cf. Definition 7.6(ii)) is provided by the Γ-equivariance of $\mathcal{L}_\alpha$). In what follows, assume that $\{(\alpha, u(\alpha)) \colon \alpha \in (\alpha_o - \eta, \alpha_o + \eta)\}$ is a fixed family of steady-state Γ-symmetric solutions near (α_o, u_o). Since $(\alpha, \beta, u(\alpha))$, $\alpha \in (\alpha_o - \eta, \alpha_o + \eta)$, $\beta \in \mathbb{R}_+$, is clearly a solution to (171) belonging to $\mathcal{P} \times \mathbb{E}^G$, consider it as a *trivial solution*. Moreover, define the map $\chi \colon (\alpha_o - \eta, \alpha_o + \eta) \times \mathbb{R}_+ \to \mathbb{E}^G$ by $\chi(\alpha, \beta) = (\alpha, \beta, u(\alpha))$. Then, the set of (nonsingular) Γ-symmetric steady-state solutions to (168) (cf. condition (C2)), gives rise to a manifold $M \subset \mathcal{P} \times \mathbb{E}^G$, $M := \{(\alpha, \beta, u(\alpha)) \colon \alpha \in (\alpha_o - \eta, \alpha_o + \eta),\ \beta \in \mathbb{R}_+\}$ (defined locally) satisfying the conditions (H3) and (H4).

Characteristic equation Let $(\alpha, u(\alpha))$ be a non-singular Γ-symmetric steady-state solution to (168). The linearization of (168) at $(\alpha, u(\alpha))$ leads to the following *characteristic equation* (near $(\alpha_o, u(\alpha_o))$)

$$\Delta_{\alpha; u(\alpha)}(\lambda) w := \lambda w + P(\alpha, x) w - \mathfrak{d} f_\alpha(e^{\lambda \cdot} w) = 0, \quad \lambda \in \mathbb{C}, \tag{174}$$

where the *characteristic operator* $\Delta_{\alpha; u(\alpha)} : \mathfrak{X}^c_\alpha \to L^2(\Omega; V^c)$ is defined (by (174)) using the standard complexifications of $P(\alpha, x)$ and $\mathfrak{d} f_\alpha(\varphi)$.

Observe that $\mathfrak{X}^c_\alpha$ equipped with the H^2-norm is a complex Hilbert space such that the embedding $\mathfrak{X}^c_\alpha \hookrightarrow L^2(\Omega; V^c)$ is compact, $P(\alpha, x)$ is an elliptic self-adjoint operator (thus, it is a bounded Fredholm operator of index zero from $\mathfrak{X}^c_\alpha$ to $L^2(\Omega; V^c)$), and $\mathfrak{d} f_\alpha(e^{\lambda \cdot} \cdot)$ is a bounded linear operator for all $\lambda \in \mathbb{C}$, therefore $\Delta_{\alpha; u(\alpha)}(\lambda) : \mathfrak{X}^c_\alpha \to L^2(\Omega; V^c)$, where $\mathfrak{X}^c_\alpha$ is equipped with the H^2-norm, is a bounded Fredholm operator of index zero.[4] Consequently, $\Delta_{\alpha; u(\alpha)}(\lambda)$ is a closed (unbounded) Fredholm operator of index zero from $L^2(\Omega; V^c)$ to itself.

A number $\lambda \in \mathbb{C}$ is called a *characteristic root* of the system (168) at a Γ-symmetric steady-state solution $(\alpha, u(\alpha))$ if $\ker \Delta_{\alpha; u(\alpha)}(\lambda) \neq \{0\}$. It is clear that a Γ-symmetric steady-state solution $(\alpha, u(\alpha))$ is non-singular if and only if 0 is not a characteristic root of

---

[4] $\Delta_{\alpha; u(\alpha)}(\lambda)$ is a sum of the compact operator $\lambda \,\mathrm{Id} - \mathfrak{d} f_\alpha(e^{\lambda \cdot} \cdot) : \mathfrak{X}^c_\alpha \to L^2(\Omega; V^c)$ and the Fredholm operator $P(\alpha, x)$ of index zero.

(168) at $(\alpha, u(\alpha))$. We say that a non-singular Γ-symmetric steady-state solution (α_o, u_o), $u_o = u(\alpha_o)$, is a *center* if it has a purely imaginary characteristic root $\mathrm{i}\beta_o$, $\beta_o > 0$, i.e. $\ker \Delta_{\alpha_o;u_o}(\mathrm{i}\beta_o) \neq \{0\}$. A center (α_o, u_o) is called *isolated* if it is the only center in some neighborhood of (α_o, u_o) in $\mathbb{R} \oplus L^2(\Omega; V)$.

For the purpose of studying the local Hopf bifurcation problem for (168), assume:

(C3) There exists a Γ-symmetric steady-state solution $(\alpha_o, u_o) \in \mathbb{R} \oplus L^2(\Omega; V)$ to (168), which is an isolated center such that $\mathrm{i}\beta_o$ (for $\beta_o > 0$) is a characteristic root of (168) for $\alpha = \alpha_o$.

Thus, condition (H5) from Subsection 7.1 is satisfied. Also, notice that (C3) is the necessary condition for the occurrence of the Hopf bifurcation at (α_o, u_o), while (C2) excludes the appearance of the "steady-state" bifurcation.

Apply the "eigenspace" reduction to describe the characteristic roots of the system (168) at the Γ-symmetric steady-state solution $(\alpha, u(\alpha))$. Denote by $\sigma_\alpha \subset \mathbb{R}$ the spectrum of the self-adjoint operator $P(\alpha, x) : \mathfrak{X}^c_\alpha \subseteq L^2(\Omega; V^c) \to L^2(\Omega; V^c)$. Since $P(\alpha, x)$ is a uniformly elliptic differential operator, the spectrum σ_α is discrete and all the eigenvalues $\mu^\alpha_{\mathfrak{k}}$ are real of finite multiplicity and such that

$$\mu^\alpha_o < \mu^\alpha_1 < \ldots < \mu^\alpha_{\mathfrak{k}} < \cdots .$$

Using the fact that for every $r > 0$, the number ir is not in the spectrum σ_α of $P(\alpha, x)$, the (auxiliary) operator $S : L^2(\Omega; V^c) \to L^2(\Omega; V^c)$ defined by

$$Sw = \mathrm{i}rw, \quad w \in L^2(\Omega; V^c),$$

is a Γ-equivariant resolvent (cf. Remark and Notation 2.17 and Definition 7.1) of $P(\alpha, x)$, i.e. the (bounded) inverse $\widetilde{R}_{\alpha,r} := [P(\alpha, x) + S]^{-1} : L^2(\Omega; V^c) \to L^2(\Omega; V^c)$ exists for all $\alpha \in \mathbb{R}$ and is Γ-equivariant. On the other hand, since $P(\alpha, x) + S$, as a (bounded) operator from the space $\mathfrak{X}^c_\alpha$ (equipped with the Sobolev H^2-norm) is also invertible and the embedding $\mathfrak{X}^c_\alpha \hookrightarrow L^2(\Omega; V^c)$ is compact, we obtain that the inverse $\widetilde{R}_{\alpha,r} : L^2(\Omega; V^c) \to L^2(\Omega; V^c)$ (i.e. $\widetilde{R}_{\alpha,r}$ is considered here as the inverse of the *unbounded* operator $P(\alpha, x) + S$ from $L^2(\Omega; V^c)$ into itself) is a compact Γ-equivariant operator. Eq. (174) can be rewritten as

$$\tilde{\Delta}^r_{\alpha;u(\alpha)}(\lambda)w := w - \mathfrak{d} f_\alpha\big(\mathrm{e}^{\lambda\cdot}\widetilde{R}_{\alpha,r}(w)\big) + (\lambda - \mathrm{i}r)\widetilde{R}_{\alpha,r}(w) = 0. \tag{175}$$

It is clear that $\lambda \in \mathbb{C}$ is a characteristic root of the system (168) at the Γ-symmetric steady-state solution $(\alpha, u(\alpha))$ if and only if $\ker \tilde{\Delta}^r_{\alpha;u(\alpha)}(\lambda) \neq \{0\}$. Also, $\tilde{\Delta}^r_{\alpha;u(\alpha)}(\lambda)$ is an analytic function in λ (cf. [145]), hence all the characteristic roots λ are isolated. Moreover, $\tilde{\Delta}^r_{\alpha;u(\alpha)}(\lambda)$ is a Γ-equivariant compact field, thus it is a bounded Γ-equivariant Fredholm operator of index zero.

Denote by $E^\alpha_{\mathfrak{k}} \subset L^2(\Omega; V^c)$ the eigenspace of $P(\alpha, x)$ corresponding to $\mu^\alpha_{\mathfrak{k}} \in \sigma_\alpha$, and let $\mathfrak{p}^\alpha_{\mathfrak{k}} : L^2(\Omega; V^c) \to E^\alpha_{\mathfrak{k}}$ be the orthogonal projection. Consequently, for every $w \in$

$L^2(\Omega; V^c)$, we have $w = \sum_{\mathfrak{k}=0}^{\infty} \mathfrak{p}^{\alpha}_{\mathfrak{k}}(w)$. By substituting $w = \sum_{\mathfrak{k}=0}^{\infty} \mathfrak{p}^{\alpha}_{\mathfrak{k}}(w)$ into (175), we obtain

$$\sum_{\mathfrak{k}=0}^{\infty}\left[\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w) - \frac{1}{\mu^{\alpha}_{\mathfrak{k}} + \mathrm{i}r}\mathfrak{d} f_{\alpha}\big(\mathrm{e}^{\lambda\cdot}\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w)\big) + \frac{\lambda - \mathrm{i}r}{\mu^{\alpha}_{\mathfrak{k}} + \mathrm{i}r}\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w)\right] = 0. \tag{176}$$

Denote by $F^{\alpha}_{\mathfrak{k}}$ the subspace of $\mathfrak{C}$ spanned by functions of the type $t \to \varphi(t)w$, where $\varphi \in C([-\tau, 0]; \mathbb{C})$ and $w \in E^{\alpha}_{\mathfrak{k}}$. We need the following hypothesis (cf. [90,119])

(C4) $\mathfrak{d} f_{\alpha}(F^{\alpha}_{\mathfrak{k}}) \subset E^{\alpha}_{\mathfrak{k}}$ for all Γ-symmetric steady-state solutions $(\alpha, u(\alpha))$ and $\mathfrak{k} = 0, 1, 2, \ldots$.

REMARK 7.7. The condition (C4) is required mainly to simplify the computation of the characteristic roots through a reduction to isotypical components of $L^2(\Omega, V^c)$ (see also [117,118]). One can check that the reaction–diffusion systems with delay of the type considered in [34–36] satisfy (C4). In the case of a parabolic system of Γ-symmetric PDEs (without delay), or the reaction–diffusion logistic equation with delay, (C4) is automatically satisfied.

Under the assumption (C4), Eq. (176) can be reduced to the following sequence of equations

$$\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w) - \frac{1}{\mu^{\alpha}_{\mathfrak{k}} + \mathrm{i}r}\mathfrak{d} f_{\alpha}\big(\mathrm{e}^{\lambda\cdot}\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w)\big) + \frac{\lambda - \mathrm{i}r}{\mu^{\alpha}_{\mathfrak{k}} + \mathrm{i}r}\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w) = 0, \quad \mathfrak{k} = 0, 1, \ldots. \tag{177}$$

Equation (177) can be written in the equivalent form as

$$(\mu^{\alpha}_{\mathfrak{k}} + \lambda)\mathfrak{p}^{\alpha}_{\mathfrak{k}}(w) + \mathfrak{d} f_{\alpha}\big(\mathrm{e}^{\lambda\cdot}\rho^{\alpha}_{\mathfrak{k}}(w)\big) = 0, \quad \mathfrak{k} = 0, 1, \ldots. \tag{178}$$

Under the assumptions (C1)–(C4), for any compact subset $X \subset \mathcal{P}$, the system (168) leads to a parametrized equivariant coincidence problem of the type (160) satisfying the conditions (H1)–(H5) (cf. (172)). Hence, given an isolated center (α_o, u_o) with the corresponding characteristic root $i\beta_o$ (cf. condition (C3)), and following the scheme outlined in Subsection 7.1 (cf. (164)–(167)), one can associate to (α_o, β_o, u_o) the local bifurcation invariant $\omega(\lambda_o, u_o) = \omega(\alpha_o, \beta_o, u_o) \in A^t_1(\Gamma \times S^1)$.

7.3. *Computation of local bifurcation invariant*

In order to obtain an effective computational formula for $\omega(\alpha_o, \beta_o, u_o)$, we need to discuss the so-called *negative spectrum* and *crossing numbers*.

Negative spectrum For the sake of simplicity, assume that Γ is a finite group and, moreover, Γ_1 acts trivially on V'. Assume that V and V^c admit the isotypical decompositions (113) with $V_0 = V^{\Gamma}$ and $U_0 = (V^c)^{\Gamma}$. Moreover, these decompositions are required to correspond to a complete list of the irreducible Γ-representations $\mathcal{V}_0, \mathcal{V}_1, \ldots, \mathcal{V}_r$ (resp.

$\mathcal{U}_0, \mathcal{U}_1, \dots, \mathcal{U}_s$). As in the previous sections, we do not exclude the possibility that some of these Γ-isotypical components are trivial. Clearly, (113) induces the Γ-isotypical decompositions

$$L^2(\Omega;\, V) = \bigoplus_{i=0}^{r} \mathfrak{V}_i, \qquad L^2(\Omega;\, V^c) = \bigoplus_{j=0}^{s} \mathfrak{U}_j, \tag{179}$$

where $\mathfrak{V}_i$ (resp. $\mathfrak{U}_j$) denotes the Γ-isotypical component of $L^2(\Omega;\, V)$ (resp. $L^2(\Omega;\, V^c)$) modeled on $\mathcal{V}_i$ (resp. $\mathcal{U}_j$).

Consider the operator $P(\alpha_o, x) : \mathfrak{X}_{\alpha_o} \subseteq L^2(\Omega;\, V) \to L^2(\Omega;\, V)$ and let K be the orthogonal projection on its kernel. Then, K is a Γ-equivariant resolvent of $P(\alpha_o, x)$. Put $\widetilde{R}_{\alpha_o} := [P(\alpha_o, x) + K]^{-1}$ and define

$$\mathcal{A} := \mathrm{Id} - \frac{1}{\beta_o} \widetilde{R}_{\alpha_o} \circ D_u \bar{f}(\alpha_o, u_o) - \widetilde{R}_{\alpha_o} K : L^2(\Omega;\, V) \to L^2(\Omega;\, V), \tag{180}$$

which is clearly a compact field. Put $\mathcal{A}^i := \mathcal{A}_{|\mathfrak{V}_i} : \mathfrak{V}_i \to \mathfrak{V}_i$ and let $\sigma_-(\mathcal{A})$ denote the set of all negative eigenvalues of the operator $\mathcal{A}$. Since $\mathcal{A}$ is a compact field, it is a Fredholm operator of index 0, the set $\sigma_-(\mathcal{A})$ is finite and all the eigenvalues in $\sigma_-(\mathcal{A})$ are of finite multiplicity. Thus, for $\mu \in \sigma_-(\mathcal{A})$, define

$$\begin{aligned} E(\mu) &:= \bigcup_{k=1}^{\infty} \ker[\mathcal{A} - \mu\, \mathrm{Id}]^k, \\ E_i(\mu) &:= \bigcup_{k=1}^{\infty} \ker[\mathcal{A}^i - \mu\, \mathrm{Id}_{|\mathfrak{V}_i}]^k, \\ m_i(\mu) &:= \dim E_i(\mu) / \dim \mathcal{V}_i, \end{aligned} \tag{181}$$

where $E_i(\mu)$ is referred to as a $\mathcal{V}_i$*-isotypical* eigenspace of the operator $\mathcal{A}$ and the integer $m_i(\mu)$ is called the $\mathcal{V}_i$*-multiplicity* of μ.

Crossing numbers Put $\tilde{\Delta}^r_{\alpha;u(\alpha),j}(\lambda) := \tilde{\Delta}^r_{\alpha;u(\alpha)}(\lambda)|_{\mathfrak{U}_j}$ (cf. (175) and (179)). For a characteristic root λ of the system (168) at the Γ-symmetric steady-state solution (α_o, u_o), we use the following notations:

$$\begin{aligned} E_j(\lambda) &:= \bigcup_{k=1}^{\infty} \ker\big[\tilde{\Delta}^r_{\alpha;u(\alpha),j}(\lambda)\big]^k, \\ m_j(\lambda) &:= \dim E_j(\lambda) / \dim \mathcal{U}_j, \end{aligned} \tag{182}$$

where the integer $m_j(\lambda)$ is called the $\mathcal{U}_j$*-multiplicity* of the characteristic root λ. Notice that, since $\tilde{\Delta}^r_{\alpha;u(\alpha),j}(\lambda)$ is a Fredholm operator of index 0, $m_j(\lambda) < \infty$ for all characteristic roots λ.

Let $(\alpha_o, u_o) \in \mathbb{R} \oplus L^2(\Omega; V)$ be an isolated center with $\mathrm{i}\beta_o$ $(\beta_o > 0)$ being the corresponding characteristic root as described in condition (C3). Define the set

$$\mathcal{S} = \left\{\tau + \mathrm{i}\beta\colon\ 0 < \tau < \delta, |\beta - \beta_o| < \varepsilon\right\} \subset \mathbb{C},$$

where $\delta > 0$ and $\varepsilon > 0$ are so small numbers that for all $\tau + \mathrm{i}\beta \in \partial\mathcal{S}$ and $\alpha \in [\alpha_o - \varepsilon, \alpha_o + \varepsilon]$, $\ker \Delta_{\alpha;u(\alpha)}(\tau + \mathrm{i}\beta) \neq \{0\}$ implies $\alpha = \alpha_o$ and $\tau + \mathrm{i}\beta = \mathrm{i}\beta_o$. Put $\alpha_\pm := \alpha_o \pm \varepsilon$ and denote by $\mathfrak{s}_\pm$ the set of all characteristic roots $\lambda \in \mathcal{S}$ for $\alpha = \alpha_\pm$, i.e.

$$\mathfrak{s}_\pm := \left\{\lambda \in \mathcal{S}\colon\ \ker \Delta_{\alpha_\pm;u(\alpha_\pm)}(\lambda) \neq \{0\}\right\}.$$

Since $\ker \Delta_{\alpha_\pm;u(\alpha_\pm)}(\lambda) = \ker \tilde{\Delta}^r_{\alpha_\pm;u(\alpha_\pm)}(\lambda)$ and $\tilde{\Delta}^r_{\alpha_\pm;u(\alpha_\pm)}(\lambda)$ is an analytic function in λ, the sets $\mathfrak{s}_\pm$ are finite. Then, for $j = 0, 1, 2, \ldots, s$ (corresponding to the complex Γ-irreducible representations $\mathcal{U}_j$), put

$$\mathfrak{t}_j^\pm(\alpha_o, \beta_o, u_o) := \sum_{\lambda \in \mathfrak{s}_\pm} m_j(\lambda) \tag{183}$$

(cf. (182)).

DEFINITION 7.8. The *$\mathcal{V}_{j,l}$-isotypical crossing numbers* of (α_o, β_o, u_o) are defined as follows:

$$\mathfrak{t}_{j,1}(\alpha_o, \beta_o, u_o) := \mathfrak{t}_j^-(\alpha_o, \beta_o, u_o) - \mathfrak{t}_j^+(\alpha_o, \beta_o, u_o), \tag{184}$$

where $\mathfrak{t}_j^\pm(\alpha_o, \beta_o, u_o)$ are given by (183), and in the case $\mathrm{i}l\beta_o$ is also a characteristic root of (168) at (α_o, u_o) for some integer $l > 1$ (cf. Definition 4.8),

$$\mathfrak{t}_{j,l}(\alpha_o, \beta_o, u_o) := \mathfrak{t}_{j,1}(\alpha_o, l\beta_o, u_o).$$

Local bifurcation result By applying the standard steps, one can establish the following formula for the local bifurcation invariant:

$$\begin{aligned}&\omega(\alpha_o, \beta_o, u_o)\\ &\quad := \left(\prod_{\mu \in \sigma_-(\mathcal{A})} \prod_{i=0}^{r} (\deg_{\mathcal{V}_i})^{m_i(\mu)}\right) \cdot \sum_{j,l} \mathfrak{t}_{j,l}(\alpha_o, \beta_o, u_o) \deg_{\mathcal{V}_{j,l}}.\end{aligned} \tag{185}$$

Combining the concept of the dominating orbit types with Theorem 7.5 (see also Remark 5.2) and using the same argument as in Sections 4 and 5 (cf. Theorems 4.9 and 5.4), one can prove the following

THEOREM 7.9. *Suppose that the system* (168) *satisfies the assumption* (C1) *and* (C4), *and suppose that* (α_o, u_o) *is a* Γ*-symmetric steady-state solution to* (168) (*cf. Definition* 7.6) *satisfying* (C2)–(C3), $\omega(\alpha_o, \beta_o, u_o)$ *is given by* (167) (*with* $\lambda_o = (\alpha_o, \beta_o)$, $\mathfrak{F}_\varsigma$ *defined by* (166), $U(r)$ *by* (164) *and* ς *satisfying* (165)). *Assume* (*cf.* (185)) $\omega(\alpha_o, \beta_o, u_o) \neq 0$, *i.e.*

$$\omega(\alpha_o, \beta_o, u_o) = \sum_{(H)} n_H(H) \quad \text{and} \quad n_{H_o} \neq 0 \tag{186}$$

for some $(H_o) \in \Phi_1^t(G)$.

(i) *Then, there exists a branch of non-trivial solutions to* (168) *with symmetries at least* H_o (*considered in the space* $\mathbb{F}$ (*cf.* (170))) *bifurcating from the point* (α_o, u_o) (*with the limit frequency* $l\beta_o$ *for some* $l \in \mathbb{N}$).

(ii) *If, in addition,* (H_o) *is a dominating orbit type in* $\mathbb{F}$, *then there exist at least* $|G/H_o|_{S^1}$ *different branches of periodic solutions to Eq.* (168) *bifurcating from* (α_o, u_o). *Moreover, for each* (α, β, u) *belonging to these branches of* (*nontrivial*) *solutions, one has* $(G_u) = (H_o)$ (*considered in the space* $\mathbb{F}$).

7.4. *Bibliographical remarks*

The general functional framework for abstract coincidence problem for unbounded parametrized Fredholm operators was studied in [90]. The equivariant situation was considered in [16]. For additional references, see [34–36,117,118].

8. Applications

In this section we consider three concrete models of practical meaning, which can be studied using the methods developed in the previous sections.

Throughout this section, V stands for an orthogonal representation of a group Γ which, for the sake of simplicity, is supposed to be one of the following *finite* groups: the dihedral groups D_8, D_{12} and the icosahedral group (i.e. the alternating group of five elements) A_5. The notations used in this section are explained in Appendix A. For all other details, we refer to [19].

8.1. Γ-*symmetric FDEs describing configurations of identical oscillators*

Model Consider a ring of 8 identical cells (for example, being chemical oscillators) coupled symmetrically by diffusion between the adjacent cells. Denote by $x^j(t)$ the concentration of the chemical substance in the j-th cell. The coupling is taking place between adjacent cells connected by the edges of a regular 8-gon. More precisely, the coupling strength between cells is represented by a function $h : \mathbb{R} \to \mathbb{R}$, in general non-linear. Since the coupling strength between the adjacent j-th and i-th cells may be non-linear as well, and depending on the concentrations x^j and x^i, we assume that it is of the form

$$h\big(x^j(t)\big)\big(g(\alpha, x_t^j) - g(\alpha, x_t^i)\big).$$

This term is supported by the ordinary law of diffusion, which simply means that the chemical substance moves from a region of greater concentration to a region of less concentration, at rate proportional to the gradient of the concentration.

The following system of delayed differential equations represents the simplest mathematical model for the above process:

$$\frac{\mathrm{d}}{\mathrm{d}t}x(t) = -\alpha x(t) + \alpha H\big(x(t)\big) \cdot C\big(G\big(x(t-1)\big)\big), \tag{187}$$

where

$$x = \begin{bmatrix} x^1 \\ x^2 \\ \vdots \\ x^8 \end{bmatrix}, \quad H(x) = \begin{bmatrix} h(x^1) \\ h(x^2) \\ \vdots \\ h(x^8) \end{bmatrix}, \quad G(x) = \begin{bmatrix} g(x^1) \\ g(x^2) \\ \vdots \\ g(x^8) \end{bmatrix},$$

the product '$\cdot$' is defined on the vectors by component-wise multiplication, and

(G1) The functions $h, g : \mathbb{R} \to \mathbb{R}$ are continuously differentiable, $h(t) \neq 0$ for all $t \in \mathbb{R}$, $g(0) = 0$, $g'(0) > 0$ and C is a symmetric 8×8-matrix of the type

$$C = \begin{bmatrix} c & d & 0 & 0 & 0 & 0 & 0 & d \\ d & c & d & 0 & 0 & 0 & 0 & 0 \\ 0 & d & c & d & 0 & 0 & 0 & 0 \\ 0 & 0 & d & c & d & 0 & 0 & 0 \\ 0 & 0 & 0 & d & c & d & 0 & 0 \\ 0 & 0 & 0 & 0 & d & c & d & 0 \\ 0 & 0 & 0 & 0 & 0 & d & c & d \\ d & 0 & 0 & 0 & 0 & 0 & d & c \end{bmatrix} \tag{188}$$

which clearly commutes with an orthogonal D_8-representation.

Therefore, conditions (A1)–(A3) from Subsection 6.1 are satisfied for the system (187).

Characteristic values To verify the remaining conditions (A4)–(A5), consider the linearization of the system (187) at $(\alpha, 0)$:

$$\frac{\mathrm{d}}{\mathrm{d}t}x(t) = -\alpha x(t) + \alpha h(0)g'(0)C\big(x(t-1)\big),$$

and put

$$\eta := h(0)g'(0). \tag{189}$$

Thus, the condition (A4) for the system (187) amounts to

$$\prod_{i=0}^{4}[-\alpha + \alpha\eta\xi_i] \neq 0, \tag{190}$$

where $\xi_0, \xi_1, \xi_2, \xi_3, \xi_4$ are the eigenvalues of the matrix C given by

$$\xi_i := c + 2d\cos\frac{i2\pi}{8}, \quad i = 0, 1, 2, 3, 4, \tag{191}$$

i.e.

$$\begin{aligned} &\xi_0 := c + 2d, && \xi_1 := c + d\sqrt{2}, \\ &\xi_2 := c, && \xi_3 := c - d\sqrt{2}, \\ &\xi_4 := c - 2d, \end{aligned}$$

and the eigenspace $E(\xi_i)$, for $i = 0, 1, 2, 3$ corresponding to the eigenvalue ξ_i is equivalent to the irreducible D_8-representation $\mathcal{V}_i$, while $E(\xi_4)$ is equivalent to $\mathcal{V}_5$ (cf. Appendix A and [19]). Moreover,

$$\Delta_\alpha(\lambda) = (\lambda + \alpha)\,\mathrm{Id} - \alpha\eta e^{-\lambda} C.$$

Therefore, a number $\lambda \in \mathbb{C}$ is a characteristic root of (141) at the stationary point $(\alpha_o, 0)$ if and only if

$$\det\nolimits_{\mathbb{C}} \Delta_\alpha(\lambda) = \prod_{i=1}^{k} [\lambda + \alpha - \alpha\eta\xi_i e^{-\lambda}] = 0. \tag{192}$$

To find a root $\lambda \in \mathbb{C}$ of the system (192), consider the following equation

$$\lambda + \alpha - \alpha\eta\xi_o e^{-\lambda} = 0, \tag{193}$$

where ξ_o is an eigenvalue of C. Obviously, $\xi_o \neq 0$ (otherwise $\lambda = -\alpha \in \mathbb{R}$ cannot be purely imaginary). A similar reason forces

$$\alpha \neq 0. \tag{194}$$

By direct computation, $\lambda = i\beta$ is a purely imaginary root of (193) if

$$\begin{cases} \cos\beta = \dfrac{1}{\eta\xi_o}, \\ \sin\beta = -\dfrac{1}{\alpha\eta\xi_o}\beta. \end{cases} \tag{195}$$

For the sake of simplicity, in our computations of the local bifurcation invariants, we take concrete values of the numbers c, d and η, involved in (195). For example, put

$$c = 2, \quad d = 3, \quad \eta = 6.$$

Then, clearly $|\frac{1}{\xi_i\eta}| < 1$ for $i = 0, 1, 2, 3, 4$, there exists $\beta_i \in (0, \pi]$ such that $\cos\beta_i = \frac{1}{\eta\xi_i}$, and, in addition, it is possible to find a unique $\alpha_i = -\beta_i\cot\beta_i$ (which clearly satisfies conditions (A4) and (A5) from Subsection 6.1). The approximate values of the pairs of solutions (α_o, β_o) to (195) are:

$$\begin{aligned}
(\alpha_0, \beta_0) &= (-0.03229787433, 1.549961486),\\
(\alpha_1, \beta_1) &= (-0.04123910887, 1.544095051),\\
(\alpha_2, \beta_2) &= (-0.1243798137, 1.487366240),\\
(\alpha_3, \beta_3) &= (0.1226042867, 1.645182058),\\
(\alpha_4, \beta_4) &= (0.06724485806, 1.612475059).
\end{aligned}$$

Crossing numbers In order to determine the value of the crossing number associated with a purely imaginary characteristic root $\lambda_o = \mathrm{i}\beta_o$, compute (by implicit differentiation) $\frac{\mathrm{d}}{\mathrm{d}\alpha}u(\alpha)$. By following the same lines as in [19], we obtain that

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}u|_{\alpha=\alpha_o} = \frac{\beta_o^2}{\alpha_o((\alpha_o+1)^2+\beta_o^2)},$$

thus

$$\operatorname{sign}\frac{\mathrm{d}}{\mathrm{d}\alpha}u|_{\alpha=\alpha_o} = \operatorname{sign}\alpha_o.$$

Consider an eigenvalue $\xi_k \in \sigma(C)$. Then, there is exists a purely imaginary characteristic root $\mathrm{i}\beta_k$, $\beta_k > 0$, of the characteristic equation (192) for $\alpha = \alpha_k$, where

$$\cos\beta_k = -\frac{1}{\eta\xi_k}, \qquad \alpha_k = \frac{\beta_k}{\eta\xi_k \sin\beta_k}$$

and consequently,

$$\begin{aligned}
&\text{if } \alpha_k > 0, \qquad \text{then } \mathfrak{t}_{j,1}(\alpha_k, \beta_k) = -m_j(\mathrm{i}\beta_k) = -1;\\
&\text{if } \alpha_k < 0, \qquad \text{then } \mathfrak{t}_{j,1}(\alpha_k, \beta_k) = m_j(\mathrm{i}\beta_k) = 1.
\end{aligned}$$

Notice that in our case, for the chosen values of c, d and η, all the crossing numbers $\mathfrak{t}_{j,l}(\alpha_k, \beta_k), l > 1$, are zero.

Negative spectrum σ_- We have $A := a_0(\alpha_k, \beta_k) = -\alpha_k \operatorname{Id} + \alpha_k h(0)g'(0)C = -\alpha_k \operatorname{Id} + \alpha_k \eta C$ (cf. (89), (90) and Subsection 5.2), so

$$\sigma(A) = \{\mu\colon\ \mu = -\alpha_k + \alpha_k\eta\xi,\ \xi \in \sigma(C)\}.$$

By direct computations, for the bifurcation points (α_k, β_k) we have the following sets σ_-:

$$\begin{aligned}
&(\alpha_0, \beta_0): && \sigma_- = \{-\alpha_0 + \alpha_0\eta\xi_0, -\alpha_0 + \alpha_0\eta\xi_1, -\alpha_0 + \alpha_0\eta\xi_2\},\\
&(\alpha_1, \beta_1): && \sigma_- = \{-\alpha_1 + \alpha_1\eta\xi_0, -\alpha_1 + \alpha_1\eta\xi_1, -\alpha_1 + \alpha_1\eta\xi_2\},\\
&(\alpha_2, \beta_2): && \sigma_- = \{-\alpha_2 + \alpha_2\eta\xi_0, -\alpha_2 + \alpha_2\eta\xi_1, -\alpha_2 + \alpha_2\eta\xi_2\},\\
&(\alpha_3, \beta_3): && \sigma_- = \{-\alpha_3 + \alpha_3\eta\xi_3, -\alpha_3 + \alpha_3\eta\xi_4\},\\
&(\alpha_4, \beta_4): && \sigma_- = \{-\alpha_4 + \alpha_4\eta\xi_3, -\alpha_4 + \alpha_4\eta\xi_4\}.
\end{aligned}$$

Maple© input data Consequently (for the chosen values of c, d and η), we obtain the following input data for the computation of the exact value of the local bifurcation invariants

(α_o, β_o)	$\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \varepsilon_6$	$\mathfrak{t}_0, \mathfrak{t}_1, \mathfrak{t}_2, \mathfrak{t}_3, \mathfrak{t}_4, \mathfrak{t}_5, \mathfrak{t}_6$
(α_0, β_0)	1,1,1,0,0,0,0	1,0,0,0,0,0,0
(α_1, β_1)	1,1,1,0,0,0,0	0,1,0,0,0,0,0
(α_2, β_2)	1,1,1,0,0,0,0	0,0,1,0,0,0,0
(α_3, β_3)	0,0,0,1,0,1,0	0,0,0,−1,0,0,0
(α_4, β_4)	0,0,0,1,0,1,0	0,0,0,0,0,−1,0

Table of results Finally, based on the fact that (D_8^d), (D_8), $(\widetilde{D}_4^d)$, (D_4^d), $(\mathbb{Z}_8^{t_1})$, $(\mathbb{Z}_8^{t_2})$, $(\mathbb{Z}_8^{t_3})$, $(\widetilde{D}_2^d)$ and (D_2^d) are the dominating orbit types in W, we are able to establish the following table of the local bifurcation invariants for each the bifurcation point (α_i, β_i), $i = 0, 1, 2, 3, 4$:

(α_i, β_i)	$\omega(\alpha_i, \beta_i)$	# of branches
(α_0, β_0)	$-(D_8) + (\widetilde{D}_2) + (D_2) - (\widetilde{D}_1) - (D_1) - (\mathbb{Z}_2) + (\mathbb{Z}_1)$	1
(α_1, β_1)	$-(\mathbb{Z}_8^{t_1}) + (\widetilde{D}_2^d) + (D_2^d) - (\widetilde{D}_1^z) - (\widetilde{D}_1) - (D_1^z) - (D_1) - (\mathbb{Z}_2^-) + 2(\mathbb{Z}_1)$	10
(α_2, β_2)	$-(\widetilde{D}_4^d) - (D_4^d) - (\mathbb{Z}_8^{t_2}) + (\widetilde{D}_2^z) + (\widetilde{D}_2) + (D_2^z) + (D_2) + (\mathbb{Z}_4^d)$ $- (\widetilde{D}_1^z) - (\widetilde{D}_1) - (D_1^z) - (D_1) - 2(\mathbb{Z}_2) + 2(\mathbb{Z}_1)$	6
(α_3, β_3)	$(\mathbb{Z}_8^{t_3}) - (\widetilde{D}_2^d) - (D_2^d) + (\widetilde{D}_1^z) + (\widetilde{D}_1) + (D_1^z) + (D_1) + (\mathbb{Z}_2^-) - 2(\mathbb{Z}_1)$	10
(α_4, β_4)	$-(D_8^d) + (D_4) + (\widetilde{D}_1^z) - (D_1)$	1

8.2. *Hopf bifurcation in symmetric configuration of transmission lines*

In this subsection, we consider two simple types of symmetric configurations for the lossless transmission line models. For all details we refer to [19].

Configuration 1: Internal coupling Consider a cube of symmetrically coupled lossless transmission line networks between two recipients and two power stations. Assume all coupled networks are identical, each of which is a uniformly distributed lossless transmission line with the inductance L_s and parallel capacitance C_s per unit length. To derive

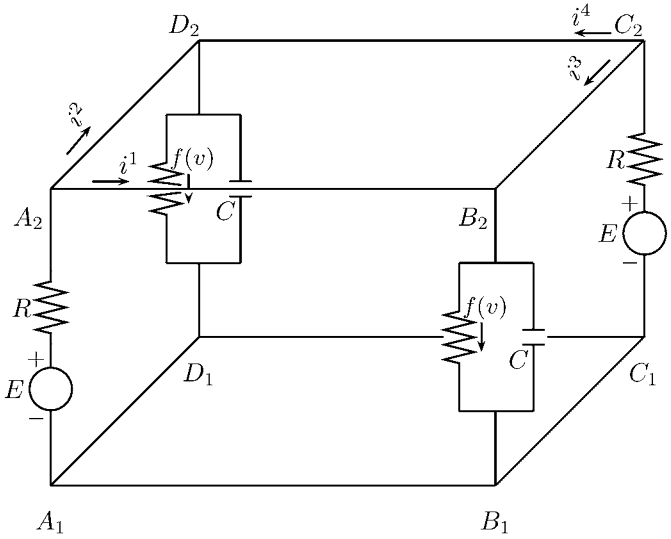

Fig. 6. Symmetric model of transmission lines: internal coupling.

the network equations, place the x-axis in the direction of the line with two ends of the normalized line at $x = 0$ and $x = 1$ (see Fig. 6).[5]

Denote by $i^j(x,t)$ the current flowing in the j-th line at time t and distance x down the line and $v^j(x,t)$ the voltage across the line at t and x, for $j = 1,2,3,4$. It is well-known that (see, for instance, [109]) the functions $i^j := i^j(x,t)$ and $v^j := v^j(x,t)$ obey the *telegrapher's equation*

$$\begin{cases} \dfrac{\partial v^j}{\partial x} = -L_s \dfrac{\partial i^j}{\partial t}, \\ C_s \dfrac{\partial v^j}{\partial t} = -\dfrac{\partial i^j}{\partial x}, \end{cases} \tag{196}$$

with the boundary conditions determined by Kirchoff law

$$\begin{cases} E = v_0^1 + (i_0^1 + i_0^2)R, \\ i_1^1 + i_1^3 = f(v_1^1) + C\dfrac{\mathrm{d}v_1^1}{\mathrm{d}t}, \\ E = v_0^3 + (i_0^3 + i_0^4)R, \\ i_1^2 + i_1^4 = f(v_1^2) + C\dfrac{\mathrm{d}v_1^2}{\mathrm{d}t}, \\ v_0^1 = v_0^2, \quad v_0^3 = v_0^4, \\ v_1^1 = v_1^3, \quad v_1^2 = v_1^4, \end{cases} \tag{197}$$

---

[5] This example of internal coupling can be easily generalized to a coupling of N recipients and N power stations with $N > 2$.

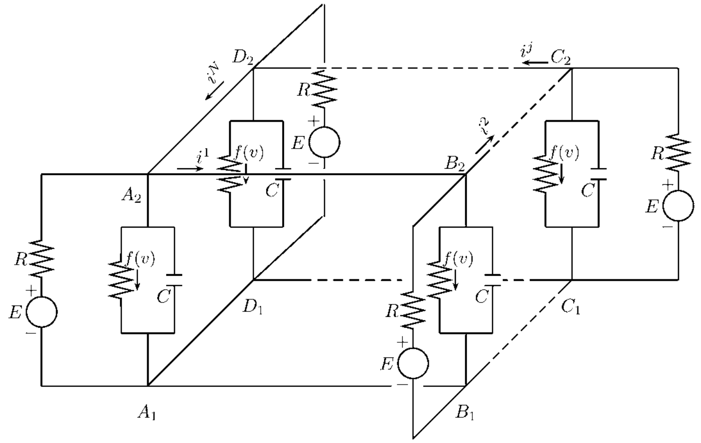

Fig. 7. Symmetric model of transmission lines: external coupling.

where $i^j_\delta = i^j_\delta(t) := i^j(\delta, t)$, $v^j_\delta = v^j_\delta(t) := v^j(\delta, t)$ for $\delta \in \{0, 1\}$, E is the constant direct current voltage and $f(v^j_1)$ is the current through the non-linear resistor in the direction shown in Fig. 6. Assume that

(E1) the boundary value problem (196)–(197) admits a unique solution $(v^j_*, i^j_*) := (v^j_*(x,t), i^j_*(x,t))$, for $j = 1, 2, 3, 4$ such that $\frac{\partial i^j_*}{\partial x} = \frac{\partial v^j_*}{\partial x} = 0$ (the so-called *equilibrium point*).

By applying standard transformations (cf. [19]) we obtain from (196) the following system of neutral functional differential equations

$$\frac{\mathrm{d}}{\mathrm{d}t}\big[x(t) - Qx(t-r)\big] = -\frac{2}{bC}x(t) - \frac{2}{bC}Qx(t-r) - \frac{1}{C}G\big(x(t)\big) + \frac{1}{C}QG\big(x(t-r)\big), \tag{198}$$

where

$$r = \frac{2}{a}, \quad x(t) = \begin{bmatrix} v^1_1(t) \\ v^2_1(t) \end{bmatrix}, \quad G\big(x(t)\big) = \begin{bmatrix} g(v^1_1(t)) \\ g(v^2_1(t)) \end{bmatrix},$$
$$Q = \begin{bmatrix} \frac{b}{2R+b} & -\frac{2R}{2R+b} \\ -\frac{2R}{2R+b} & \frac{b}{2R+b} \end{bmatrix}.$$

Configuration 2: External coupling A second example of symmetric coupling was considered in [145], where N recipients are mutually coupled via lossless transmission line network which are interconnected by a common resistor R_o between neighboring recipients, and extensively connected with N power stations (see Fig. 7).

Denote by $i^j(x,t)$ the current flowing in the j-th line at time t and distance x down the line and $v^j(x,t)$ the voltage across the line at t and x, for $j = 1, \dots, N$. The same telegrapher's equation (196) holds for $i^j(x,t)$ and $v^j(x,t)$. However, the boundary conditions need to be modified for this external coupling. For $j = 1, \dots, N$,

$$\begin{cases} E = v_0^j + i_0^j R, \\ i_1^j = f(v_1^j) + C\dfrac{\mathrm{d}v_1^j}{\mathrm{d}t} - \big(I^{j-1}(t) - I^j(t)\big), \\ v_1^j - v_1^{j+1} = I^j(t)R_o, \end{cases} \tag{199}$$

where $I^0(t) := I^N(t)$, $v^{N+1} := v^1$, I^j's are the so-called coupling terms (see [145]).

For mathematical simplicity, assume that (cf. (E1))

(E2) the boundary value problem (196) and (199) admits a unique equilibrium point $(v_*^j, i_*^j) := (v_*^j(x,t), i_*^j(x,t))$, for $j = 1, \dots, N$.

By applying similar standard transformations, the system (196) with the boundary conditions (199) can be translated to

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}\big[x(t) - \alpha x(t-r)\big] = -\frac{1}{bC}Px(t) - \frac{1}{bC}\alpha Px(t-r) - \frac{1}{C}G\big(x(t)\big) \\ + \frac{1}{C}\alpha G\big(x(t-r)\big), \end{aligned} \tag{200}$$

where

$$r = \frac{2}{a}, \quad x(t) = \begin{bmatrix} v_1^1(t) \\ \vdots \\ v_1^N(t) \end{bmatrix}, \quad G\big(x(t)\big) = \begin{bmatrix} g(v_1^1(t)) \\ \vdots \\ g(v_1^N(t)) \end{bmatrix},$$

$$\alpha = -\frac{R-b}{R+b}, \quad P = \begin{bmatrix} 1 + \frac{2b}{R_o} & -\frac{b}{R_o} & 0 & \dots & 0 & -\frac{b}{R_o} \\ -\frac{b}{R_o} & 1 + \frac{2b}{R_o} & -\frac{b}{R_o} & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ -\frac{b}{R_o} & 0 & 0 & \dots & -\frac{b}{R_o} & 1 + \frac{2b}{R_o} \end{bmatrix}.$$

Notice that (200) is a D_N-symmetric system in the following sense: consider D_N acting on $V := \mathbb{R}^N$ by permuting the coordinates of vectors

$$x = \begin{bmatrix} v^1 \\ \vdots \\ v^N \end{bmatrix} \in V,$$

then the system (200) is symmetric with respect to the D_N-action on V.

Symmetric configuration of transmission lines Being motivated by the above two generic models of symmetric couplings, we consider a general symmetric system of functional differential equations and discuss several crucial elements related to computations of its associated bifurcation invariant, which are the prerequisite for the usage of our Maple© package.

Combine the two coupling models in the following symmetric neutral functional differential equation

$$\begin{aligned}&\frac{\mathrm{d}}{\mathrm{d}t}\bigl[x(t)-\alpha Qx(t-r)\bigr]\\&\quad=-P_1x(t)-\alpha QP_2x(t-r)-aG\bigl(x(t)\bigr)+a\alpha QG\bigl(x(t-r)\bigr)\end{aligned}\tag{201}$$

where a and r are positive constants, $\alpha\in\mathbb{R}$ is the bifurcation parameter, and

$$x(t)=\begin{bmatrix}x^1(t)\\x^2(t)\\\vdots\\x^n(t)\end{bmatrix}\in\mathbb{R}^n,\qquad G\bigl(x(t)\bigr)=\begin{bmatrix}g(x^1(t))\\g(x^2(t))\\\vdots\\g(x^n(t))\end{bmatrix}\in\mathbb{R}^n.$$

For definitiveness, assume $n=12$, $r=1$, and

(H1) $g:\mathbb{R}\to\mathbb{R}$ is continuously differentiable, $g(0)=g'(0)=0$;

(H2) $\Gamma=D_{12}$ acts on $\mathbb{R}^{12}$ by permuting the coordinates of vectors $x\in V:=\mathbb{R}^{12}$, meaning geometrically it permutes the vertices of the 12-gon;

(H3)

(i) Q, P_1, P_2 are 12×12-matrices of the type:

$$C=\begin{bmatrix}c&d&0&0&0&0&0&0&0&0&0&d\\d&c&d&0&0&0&0&0&0&0&0&0\\0&d&c&d&0&0&0&0&0&0&0&0\\0&0&d&c&d&0&0&0&0&0&0&0\\0&0&0&d&c&d&0&0&0&0&0&0\\0&0&0&0&d&c&d&0&0&0&0&0\\0&0&0&0&0&d&c&d&0&0&0&0\\0&0&0&0&0&0&0&0&d&c&d&0\\0&0&0&0&0&0&0&d&c&d&0&0\\0&0&0&0&0&0&0&0&d&c&d&0\\0&0&0&0&0&0&0&0&0&d&c&d\\d&0&0&0&0&0&0&0&0&0&d&c\end{bmatrix}.\tag{202}$$

(ii) for the matrix Q, we choose $c=-\frac{1}{3}$, $d=\frac{1}{4}$; for P_1, $c=\frac{1}{2}$, $d=\frac{1}{3}$; and for P_2, $c=25$, $d=10$;

(H4) we will consider α satisfying $|\alpha|\cdot\|Q\|=\frac{5}{6}|\alpha|<1$.

REMARK 8.1.

(i) It is clear that the system (201) is symmetric with respect to the D_{12}-action on V and $(\alpha,0)$ is a stationary point for all α.

(ii) Q, P_1, P_2 are pairwisely commuting matrices. They can be diagonalized simultaneously. In other words, Q, P_1, P_2 share the same eigenspaces with respect to a certain choice of a basis of V. We use the symbols ξ, ζ and η to denote the eigenvalues of Q, P_1, and P_2 (respectively) corresponding to the same eigenvector $v \in V$.

(iii) One can verify that in the case $\zeta\eta > 0$, ζ and η satisfy $\sqrt{\zeta\eta} \neq \frac{2k+1}{2}\pi$ for any $k \in \mathbb{Z}$.

In this way, we are dealing here with a D_{12}-symmetric system of functional differential equations, and we are interested in studying a Hopf bifurcation phenomenon.

Let us organize all the eigenvalues of the matrices Q, P_1 and P_2 according to their D_{12}-isotypical type (see Appendix A):

k	ξ_k	ζ_k	η_k	Eigenspace
0	$\frac{1}{6}$	$\frac{7}{6}$	45	$\mathcal{V}_0$
1	$-\frac{1}{3}+\frac{1}{4}\sqrt{3}$	$\frac{1}{2}+\frac{1}{3}\sqrt{3}$	$25+10\sqrt{3}$	$\mathcal{V}_1$
2	$-\frac{1}{12}$	$\frac{5}{6}$	35	$\mathcal{V}_2$
3	$-\frac{1}{3}$	$\frac{1}{2}$	25	$\mathcal{V}_3$
4	$-\frac{7}{12}$	$\frac{1}{6}$	15	$\mathcal{V}_4$
5	$-\frac{1}{3}-\frac{1}{4}\sqrt{3}$	$\frac{1}{2}-\frac{1}{3}\sqrt{3}$	$25-10\sqrt{3}$	$\mathcal{V}_5$
6	$-\frac{5}{6}$	$-\frac{1}{6}$	5	$\mathcal{V}_7$

Characteristic equation and isolated centers By linearizing the system (201) at $x = 0$, we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\big[x(t) - \alpha Q x(t-1)\big] = -P_1 x(t) - \alpha Q P_2 x(t-1),$$

and substituting $x = \mathrm{e}^{\lambda t} v$ for $\lambda \in \mathbb{C}$, $0 \neq v \in V$, leads to

$$\lambda \mathrm{e}^{\lambda t} v - \alpha Q \lambda \mathrm{e}^{\lambda(t-1)} v = -P_1 \mathrm{e}^{\lambda t} v - \alpha Q P_2 \mathrm{e}^{\lambda(t-1)} v$$

i.e.

$$[\lambda \,\mathrm{Id} - \alpha Q \lambda \mathrm{e}^{-\lambda} + P_1 + \alpha Q P_2 \mathrm{e}^{-\lambda}] v = 0.$$

Therefore, we have the following characteristic equation for the system (201)

$$\det_{\mathbb{C}} \Delta_{(\alpha,0)}(\lambda) = 0, \tag{203}$$

where

$$\Delta_{(\alpha,0)}(\lambda) := (\lambda \,\mathrm{Id} - \alpha Q \lambda \mathrm{e}^{-\lambda}) + P_1 + \alpha Q P_2 \mathrm{e}^{-\lambda}.$$

†These values of α_o have to be excluded because they are not in the required interval $(-\frac{6}{5}, \frac{6}{5})$.

Next, we need to find possible values of α such that (203) has a purely imaginary root $\mathrm{i}\beta$ for some $\beta > 0$, so we could detect potential bifurcation points $(\alpha, \beta, 0) \in (-\frac{6}{5}, \frac{6}{5}) \times \mathbb{R}_+ \times W$.

By Remark 8.1(ii), when restricted to the same eigenspace of Q, P_1 and P_2, the characteristic equation (203) reduces to the following algebraic equation

$$(\lambda + \zeta)\mathrm{e}^{\lambda} - \alpha\xi(\lambda - \eta) = 0. \tag{204}$$

By replacing in (204) λ with $\mathrm{i}\beta$ and separating the real and imaginary parts, we obtain

$$\tan(\beta) = \frac{\beta(\zeta + \eta)}{\beta^2 - \zeta\eta}, \qquad \alpha = \frac{\zeta \sin\beta + \beta\cos\beta}{\beta\xi}. \tag{205}$$

The system (205) has infinitely many solutions, which can be easily estimated. In Table 3, we present some of the first values of the bifurcation points (α_o, β_o) arranged according to the isotypical type $\mathcal{V}_k$ of the eigenspace $E(\xi_k)$.

Negative spectrum σ_- Consider a bifurcation point (α_o, β_o). The spectrum $\sigma(A(\alpha_o, \beta_o))$ of the linear operator $A(\alpha_o, \beta_o) := -\frac{1}{\beta}_o D_x f(\alpha_o, 0)|_V$ is given by

$$\sigma\big(A(\alpha_o, \beta_o)\big) = \left\{\mu_k = \frac{1}{\beta}_o (\zeta_k + \alpha_o \xi_k \eta_k)\colon\ k = 0, 1, 2, 3, 4, 5, 6\right\}.$$

Therefore, the negative spectrum σ_- of $A(\alpha_o, \beta_o)$ can be obtained easily by inspection (see Table 3). The $\mathcal{V}_i$-multiplicity $m_i(\mu)$ for each $\mu \in \sigma_-$ is 1.

Crossing numbers $\mathfrak{t}_{k,1}$ For a given bifurcation point (α_o, β_o), in order to evaluate the crossing number $\mathfrak{t}_{k,1}(\alpha_o, \beta_o)$, we substitute $\lambda = u + \mathrm{i}v$ in (204), separate the real and imaginary parts, and apply implicit differentiation with respect to α at α_o, $u = 0$, $v = \beta_o$. If $\beta_o > 1$, then one can show (see [19]) that

$$\operatorname{sign}\left(\frac{\mathrm{d}u}{\mathrm{d}\alpha}(\alpha_o)\right) = \operatorname{sign}(\alpha_o).$$

Consequently, if (α_o, β_o) satisfies (205) with $\xi = \xi_k$, $\zeta = \zeta_k$ and $\eta = \eta_k$, for some $k = 0, 1, 2, 3, 4, 5, 6$, then

$$\mathfrak{t}_{k,1}(\alpha_o, \beta_o) = -\operatorname{sign}(\alpha_o).$$

Table of results In Table 4 we list the exact values of the local bifurcation invariants $\omega(\alpha_o, \beta_o)$ for all bifurcation points indicated in Table 3. The dominating orbit types in W are (D_{12}), (D_{12}^d), $(\mathbb{Z}_{12}^{t_1})$, $(\mathbb{Z}_{12}^{t_2})$, $(\mathbb{Z}_{12}^{t_3})$, $(\mathbb{Z}_{12}^{t_4})$, $(\mathbb{Z}_{12}^{t_5})$, $(\widetilde{D}_6^d)$, and (D_6^d).

8.3. *Global continuation of bifurcating branches*

Here, we apply the general results presented Subsection 6.3 to study the global behavior of branches of periodic solutions to the system (187) (with the dihedral symmetries D_8) occurring as a result of the (local) Hopf bifurcation.

By applying the same setting as in Subsection 6.1, the problem of finding periodic solutions to (187) can be reformulated as an equation of type (155), where $\mathfrak{F}$ is given by

$$\mathfrak{F}(\alpha, \beta, u) = u - \mathcal{F}(\alpha, \beta, u), \tag{206}$$

and

$$\mathcal{F}(\alpha, \beta, u)(t) = (L + K)^{-1}\left[-\frac{\alpha}{\beta}\big(u(t) - H\big(u(t)\big)\big)\cdot CG\big(u(t - \beta)\big)\big) + Ku\right]. \tag{207}$$

Throughout this subsection, we assume that the condition (G1) of Subsection 8.1 is satisfied with $c = -3$, $d = 1$, and $\eta := h(0)g'(0) = 2$.

Table 4
Classification of the D_{12}-symmetric Hopf bifurcation in (201) for selected bifurcation points

Global Hopf bifurcation in a system with dihedral symmetries D_8 The system (187) is symmetric with respect to the dihedral group $\Gamma = D_8$ acting on $V = \mathbb{R}^8$ by permuting the coordinates of vectors. In addition, $\sigma(C)$ is composed of negative numbers: $\xi_0 := -1$, $\xi_1 := -3 + \sqrt{2}$, $\xi_2 := -3$, $\xi_3 := -3 - \sqrt{2}$, $\xi_4 := -5$ and clearly $\eta\xi_o < -1$ for all $\xi_o \in \sigma(C)$. Therefore, for every $\xi_o \in \sigma(C)$, the system of Eqs. (195) has a unique solution (α_o, β_o) such that $\beta_o \in (\frac{\pi}{2}, \pi)$. We are interested in the point (α_4, β_4) (for $\xi_o = \xi_4$), which can be easily approximated, i.e. $(\alpha_4, \beta_4) \simeq (0.1679381755, 1.670963748)$. By applying the same steps as in Subsection 8.1, one can verify that the set σ_- for the point (α_4, β_4) is empty. Since the eigenspace $E(\xi_4)$ is equivalent to $\mathcal{V}_5$, we obtain that the $\mathcal{V}_5$-isotypical crossing number $\mathfrak{t}_{5,1}(\alpha_4, \beta_4) = -1$, which allows us to compute the exact value of the local bifurcation invariant

$$\omega(\alpha_4, \beta_4) = -(D_8^d).$$

Let us point out that (D_8^d) is a dominating orbit type in W. Therefore, by the local bifurcation theorem (cf. Theorem 5.4), there exists a branch $\mathcal{C} := \mathcal{C}_{(D_8^{d,l})}$ of non-constant periodic solutions of the orbit type $(D_8^{d,l})$ (for some $l \geqslant 1$), bifurcating from (α_4, β_4). Notice that $D_8^d \subset D_8^{d,l}$.

Assume in addition, the following conditions to be satisfied

(B1) $tg(t)/h(t) > 0$ for all $t \neq 0$; $\lim_{t\to\infty} tg(t)/h(t) = \infty$.

(B2) There exist constants $A, B > 0$ and $\delta, \gamma > 0$ with $1 > \delta + \gamma$ such that

$$\left|h(t)\right| \leqslant A + B|t|^\delta, \qquad \left|g(t)\right| \leqslant A + B|t|^\gamma.$$

Let us point out, that under the above assumptions one has (cf. Remark 6.11):

(a) if (α, x_o) is a stationary point for the system (187) and $\alpha \neq 0$, then $x_o = 0$;

(b) if a Hopf bifurcation occurs at (α_o, x_o), then $\alpha_o \neq 0$.

Suppose that (α, β, x) belongs to $\mathcal{C}$. Then, the D_8^d-symmetry properties of $x(t)$ can be translated as follows: $x(t) = (x^0(t), x^1(t), \dots, x^7(t))^T$ is a $\frac{2\pi}{\beta}$-periodic solution such that

$$x^k(t) = x^{k+1}\left(t - \frac{\pi}{\beta}\right) \quad (\text{mod } 8), \tag{208}$$

and

$$x^k(t) = x^{n-k-1}\left(t - \frac{\pi}{\beta}\right) \quad (\text{mod } 8). \tag{209}$$

Combining (208), (209) with condition (B1) and applying the same argument as in [94], one can easily show that the periods $p = \frac{2\pi}{\beta}$ of solutions $(\alpha, \beta, x) \in \mathcal{C}$ satisfy the inequality $2 < p < 4$. This fact immediately implies $\mathcal{C} \cap \mathbb{R}^2 \times \{0\} = (\alpha_4, \beta_4, 0)$.

Consequently, $\mathcal{C} \subset \mathbb{R} \times (\pi/2, \pi) \times W$. Further, using the assumption (B2), one can easily show that there exists a constant $M > 0$ such that for every periodic solution $x(t)$ to (187) $\sup\{\|x(t)\|: t \in \mathbb{R}\} \leqslant M$ (see [19]). Thus,

$$\mathcal{C} \subset \mathbb{R} \times (\pi/2, \pi) \times \left\{x \in W: \|x\| \leqslant M\right\}.$$

Finally, the system (187) has no non-constant periodic solution for $\alpha = 0$, from which it follows

$$\mathcal{C} \subset (0, \infty) \times (\pi/2, \pi) \times \bigl\{x \in W\colon \|x\| \leqslant M\bigr\}.$$

However, by Corollary 6.10, the connected component $\mathcal{C}$ is unbounded, therefore

$$[\alpha_{n/2}, \infty) \subset \bigl\{\alpha\colon (\alpha, \beta, x) \in \mathcal{C}\bigr\}.$$

In this way we obtained the following

THEOREM 8.2. *Consider the system* (187) *and suppose the conditions* (G1) *from Subsection* 8.1 (*with* $c = -3$, $d = 1$ *and* $\eta = 2$), (B1) *and* (B2) *are satisfied. Then, the branch* $\mathcal{C} := \mathcal{C}_{D_8^{d,l}}$ *of periodic solutions bifurcating from* $(\alpha_4, \beta_4, 0)$ *is unbounded and satisfies*

$$[\alpha_4, \infty) \subset \bigl\{\alpha\colon (\alpha, \beta, x) \in \mathcal{C}\bigr\}.$$

8.4. *Symmetric system of Hutchinson model in population dynamics*

Hutchinson model of an n species ecosystem The standard model for the dynamics of a simple (single) population (in terms of its density) is the Verhulst equation (cf. [73,70])

$$\dot{v} = \alpha v\left(1 - \frac{v}{K}\right), \tag{210}$$

which is based on the idea that the population grows exponentially at low densities and saturates towards the carrying capacity K (of resources) at high densities. The Hutchinson model (of a single species) is obtained from (210) by taking into account a delayed response to the remaining resources,

$$\dot{v}(t) = \alpha v(t)\left(1 - \frac{v(t-\tau)}{K}\right), \tag{211}$$

where $\tau > 0$ is a presumed delay constant and α refers to the intrinsic growth rate.

Consider an ecosystem composed of n species interacting with each other (according to a certain symmetry) by competing (or cooperating) over shared resources such as food and habitats, while maintaining a self-inhibiting nature (meaning self-limiting in respond to rare resources and self-reproducing to abundant resources). A mathematical treatment for such a community model was developed by Levins in [104], where one attaches a loop diagram in order to carry out a loop analysis for this community type situation.

In such a system (which is illustrated on Fig. 8), the coefficient a_{jj} describes the self-inhibiting nature of the j-th species, and $a_{ij} < 0$ (resp. $a_{ij} > 0$) is the competing (resp. cooperating) coefficient between species i and j. Also, observe that $a_{ij} = a_{ji}$.

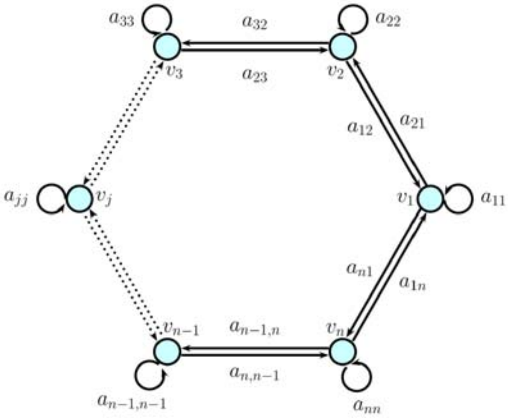

Fig. 8. System with dihedral symmetries.

Introduce

$$C = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \tag{212}$$

and call it the *community matrix*. This community ecosystem can be described by the following equations,

$$\dot{v}(t) = \alpha C v(t) \cdot \left(1 - \frac{v(t-\tau)}{K}\right), \tag{213}$$

where '$\cdot$' stands for the component-wise "vector-multiplication" $u \cdot v = [u_1 v_1, \dots, u_n v_n]^T$ for $u = [u_1, \dots, u_n]^T$ and $v = [v_1, \dots, v_n]^T$ (cf. Subsection 8.1).

By applying the standard substitution, (213) is transformed to the equivalent system

$$\dot{u}(t) = -\alpha C u(t-\tau) \cdot \big[1 + u(t)\big], \tag{214}$$

where $u(t) = v(t)/K - 1$ is, in fact, a population saturation index with respect to the available resources. In order to study the system (214) in a heterogeneous environment, we add to (214) a spatial diffusion term, which leads to the following reaction–diffusion equations

$$\frac{\partial}{\partial t} u(x,t) = d \frac{\partial^2}{\partial x^2} u(x,t) - \alpha C u(x, t-1)\big[1 + u(x,t)\big], \tag{215}$$

where $d > 0$ is a spatial diffusion coefficient.

Symmetric system of the Hutchinson model Consider a symmetric system of n species Hutchinson model of the form (215) (for $t > 0$ and $x \in (0, \pi)$)

$$\begin{cases} \dfrac{\partial}{\partial t} u(x,t) = \dfrac{\partial^2}{\partial x^2} u(x,t) - \alpha C u(x, t-1) \cdot \big[1 + u(x,t)\big], \\ \dfrac{\partial}{\partial x} u(x,t) = 0, \quad x = 0, \pi, \end{cases} \tag{216}$$

where $u : [0, \pi] \times \mathbb{R} \to \mathbb{R}^n$ is a population saturation index (cf. (214)), $d > 0$ is a spatial diffusion coefficient and $\alpha \neq 0$ is the intrinsic growth rate (cf. (211)), which is considered as a bifurcation parameter, and C is a (symmetric) community matrix describing the interaction among the species. For simplicity, in what follows, we assume that $d = 1$.

Assume that

(A1) The geometrical configuration described by the system (216) has the icosahedral symmetry group A_5. The group A_5 permutes twenty vertices of the related dodecahedron, which means it acts on $\mathbb{R}^{20}$ by permuting the coordinates of the vectors $x \in \mathbb{R}^{20}$. The (symmetric) matrix C commuting with this A_5-action is of the type:

$$C = \begin{bmatrix}
1 & 2 & 0 & 0 & 2 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\
2 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 \\
2 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 \\
0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 \\
0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 2 \\
0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 & 2 \\
0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 1 & 2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 2 & 0 & 0 & 2 & 1
\end{bmatrix}. \tag{217}$$

Under the assumption (A1), the space $V := \mathbb{R}^{20}$ becomes an orthogonal A_5-representation and the system (216) is symmetric with respect to the action of the group $\Gamma = A_5$.

Characteristic equation and isolated centers At the A_5-symmetric steady-state solution $(\alpha, 0)$ the system (216) has the linearization

$$\begin{cases} \frac{\partial}{\partial t}u(x,t) = \frac{\partial^2}{\partial x^2}u(x,t) - \alpha C u(x,t-1), \\ \frac{\partial}{\partial x}u(x,t) = 0, \quad x = 0, \pi. \end{cases} \tag{218}$$

Since the matrix C is symmetric, it is completely diagonalizable with respect to a basis composed of its eigenvectors. Consider the spectrum $\sigma(C)$ of the matrix C,

$$\sigma(C) = \{\xi_0 = 7, \xi_1 = 1, \xi_2 = -3, \xi_3 = 3, \xi_4 = 1 + 2\sqrt{5}, \xi_5 = 1 - 2\sqrt{5}\}$$

and denote by $\mathfrak{E}(\xi_k) \subset V$ the eigenspace of ξ_k. One can verify that

$$\begin{aligned} &\mathfrak{E}(\xi_0) = \mathcal{V}_0, \quad \mathfrak{E}(\xi_1) = \mathcal{V}_1, \quad \mathfrak{E}(\xi_2) = \mathcal{V}_1, \\ &\mathfrak{E}(\xi_3) = \mathcal{V}_2, \quad \mathfrak{E}(\xi_4) = \mathcal{V}_3, \quad \mathfrak{E}(\xi_5) = \mathcal{V}_4. \end{aligned}$$

Then,

$$L^2\big([0,\pi]; V\big) = \bigoplus_{k=0}^{5} L^2\big([0,\pi]; \mathfrak{E}(\xi_k)\big), \tag{219}$$

and $w \in L^2([0,\pi]; V)$ can be represented as $w(x) = \sum_k w_k(x)$, where $w_k \in L^2([0,\pi];$ $\mathfrak{E}(\xi_k))$. In a similar way, one also has

$$L^2\big([0,\pi]; V^c\big) = \bigoplus_{k=0}^{5} L^2\big([0,\pi]; \mathfrak{E}^c(\xi_k)\big), \tag{220}$$

where $\mathfrak{E}^c(\xi_k)$ denotes the complexification of the eigenspace $\mathfrak{E}(\xi_k)$.

Notice that $(\alpha, 0)$ is a Γ-symmetric steady-state solution to (216) for all (non-zero) α. Thus, we can take the set $(\alpha, \beta, 0)$, $\alpha \neq 0$, for the manifold $M \subset \mathcal{P} \times \mathbb{E}^G$ described in Subsection 7.1 (see also Subsection 7.2). Moreover, $(\alpha_o, 0)$ is non-singular if $0 \notin \sigma(\mathcal{L}_{\alpha_o})$, where $\mathcal{L}_{\alpha_o} := \frac{\partial^2}{\partial x^2} - \alpha_o C : H_0^2([0,\pi]; V) \to L^2([0,\pi); V]$ with $H_0^2([0,\pi]; V)$ being the subspace of $H^2([0,\pi]; V)$ consisting of functions u satisfying $u(0) = u(\pi) = 0$. One can easily verify that if

$$-\frac{\alpha_o \xi_k}{d} \neq m^2 \quad \text{for all } k = 0, 2, \dots, 5 \text{ and } m = 0, 1, \dots,$$

then $(\alpha_o, 0)$ is a non-singular Γ-symmetric steady-state solution, i.e. $(\alpha_o, 0)$ satisfies the condition (C2) from Subsection 7.2.

A number $\lambda \in \mathbb{C}$ is a characteristic root of the system (216) at a Γ-symmetric steady-state solution $(\alpha, 0) \in \mathbb{R} \oplus V$ if there exists a non-zero function $v \in L^2([0,\pi]; V^c)$ such that

$$\Delta_\alpha(\lambda)v(x) := \lambda v(x) - \frac{\partial^2}{\partial x^2} v(x) + \alpha e^{-\lambda} C v(x) = 0, \tag{221}$$

where we put $\Delta_\alpha := \Delta_{\alpha;0}$ (cf. (174)).

By using the decomposition (220), v can be written as $v(x) = \sum_{k=0}^{5} v_k(x)$, for $v_k(x) \in E(\xi_k)$. Consequently, (221) yields

$$\Delta_\alpha(\lambda)v(x) = \sum_k \left(\lambda v_k(x) - \frac{\partial^2}{\partial x^2} v_k(x) + \alpha e^{-\lambda} \xi_k v_k(x) \right) = 0. \tag{222}$$

Next, by using the point spectrum $\{\zeta_m := m^2\}_{m=0}^{\infty}$ of the (scalar-valued) Laplace operator $L := -\frac{\partial^2}{\partial x^2}$ and the corresponding eigenspaces $E(\zeta_m)$, we can write $v_k(x) = \sum_m v_{k,m}(x)$, for $v_{k,m} \in E(\zeta_m)$, thus

$$\Delta_\alpha(\lambda)v(x) = \sum_{k,m} \big(\lambda v_{k,m}(x) + m^2 v_{k,m}(x) + \alpha e^{-\lambda} \xi_k v_{k,m}(x) \big) = 0. \tag{223}$$

Therefore, $\lambda \in \mathbb{C}$ is a characteristic root of (216) at the Γ-symmetric steady-state solution $(\alpha, 0)$, if

$$\lambda + m^2 + \alpha \xi_k e^{-\lambda} = 0, \quad \text{for } k = 1, \ldots, 5 \text{ and } m = 0, 1, \ldots. \tag{224}$$

Computations for the local bifurcation $\Gamma \times S^1$*-invariant* In order to find the values α_o for which the condition (C3) from Subsection 7.2 holds, we need to find purely imaginary roots $\lambda = i\beta$ ($\beta > 0$) of (224). Assume that $(\alpha, 0)$ is a non-singular Γ-symmetric steady-state solution to (216) (in particular, $\alpha \neq 0$).

- **Computation for purely imaginary roots** $\lambda = i\beta$ ($\beta > 0$)

By substituting $\lambda = i\beta$ into (224),

$$\begin{cases} m^2 + \alpha \xi_k \cos\beta = 0, \\ \beta - \alpha \xi_k \sin\beta = 0, \end{cases} \quad \text{for } k = 0, \ldots, 5. \tag{225}$$

In the case $m = 0$,

$$\begin{cases} \beta := \beta_{\nu,0,k} = \dfrac{\pi}{2} + \nu\pi, \\ \alpha := \alpha_{\nu,0,k} = (-1)^\nu \dfrac{\beta}{\xi_k}, \end{cases}$$

for $k = 0, \ldots, 5$ and $\nu = 0, 1, \ldots$. Consequently,

$$\operatorname{sign} \alpha_{\nu,0,k} = (-1)^\nu \operatorname{sign} \xi_k. \tag{226}$$

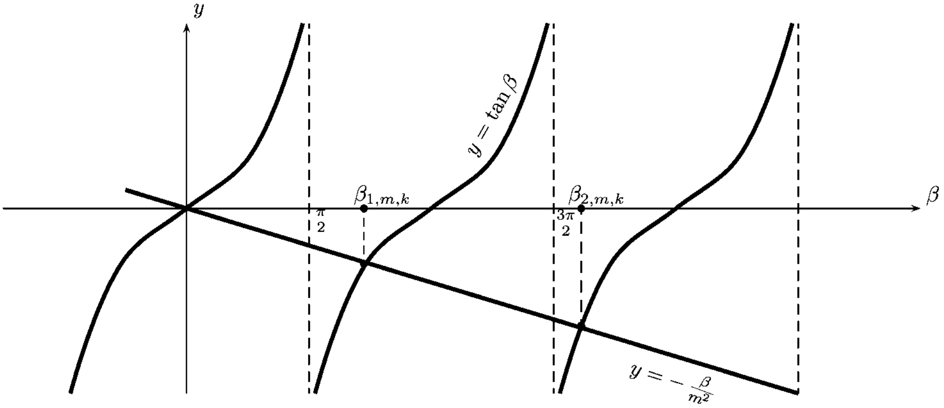

Fig. 9. Purely imaginary roots of the characteristic equation.

In the case $m \neq 0$ (thus $\cos\beta \neq 0$ by the first equation in (225)),

$$\tan\beta = -\frac{\beta}{m^2}, \tag{227}$$

$$\alpha = -\frac{m^2}{\xi_k \cos\beta}, \tag{228}$$

Eq. (227) has infinitely many positive solutions, which are denoted by $\{\beta_{\nu,m,k}\}_{\nu=1}^{\infty}$ (see Fig. 9). The corresponding solution α of (228) is denoted by $\alpha_{\nu,m,k}$. In Table 5 we list approximate values of the roots $(\alpha_{\nu,m,k}, \beta_{\nu,m,k})$ for $m = 0, 1, 2, 3$ and $\nu = 0, 1, 2, 3, 4$.

Also, notice that $\operatorname{sign}\cos\beta_{\nu,m,k} = (-1)^{\nu}$, thus by (228) for $m > 0$,

$$\operatorname{sign}\alpha_{\nu,m,k} = (-1)^{\nu+1}\operatorname{sign}\xi_k. \tag{229}$$

• **Computation for** $\operatorname{sign}\frac{\mathrm{d}}{\mathrm{d}\alpha}w(\alpha)|_{\alpha=\alpha_{\nu,m,k}}$

Put $\alpha_o := \alpha_{\nu,m,k}$ and $\beta_o := \beta_{\nu,m,k}$. In order to determine the value of the crossing number $t_{j,1}(\alpha_o, \beta_o, 0)$, compute $\frac{\mathrm{d}}{\mathrm{d}\alpha}w(\alpha)|_{\alpha=\alpha_o}$ by implicit differentiation.

By substituting $\lambda = w + \mathrm{i}v$ into (224), then, differentiating with respect to α, and substituting $\alpha = \alpha_o$, $w = 0$ and $v = \beta_o$, we obtain

$$\operatorname{sign}\frac{\mathrm{d}w}{\mathrm{d}\alpha}|_{\alpha=\alpha_o=\alpha_{\nu,m,k}} = \begin{cases} (-1)^{\nu}\operatorname{sign}\xi_k, & \text{if } m = 0,\\ (-1)^{\nu+1}\operatorname{sign}\xi_k, & \text{if } m = 1, 2, \ldots . \end{cases} \tag{230}$$

Therefore, for $m = 0$

$$\mathfrak{t}_{j,1}(\alpha_o, \beta_o) = \begin{cases} (-1)^{\nu+1}\operatorname{sign}\xi_k m_j(\mathrm{i}\beta_o), & j = j_{\beta_o},\\ 0, & j \neq j_{\beta_o}, \end{cases} \tag{231}$$

Table 5
List of approximate values of several bifurcation points (α_o, β_o) for (216)

and for $m \neq 0$

$$\mathfrak{t}_{j,1}(\alpha_o, \beta_o) = \begin{cases} (-1)^{\nu} \operatorname{sign} \xi_k \, m_j(\mathrm{i}\beta_o), & j = j_{\beta_o}, \\ 0, & j \neq j_{\beta_o}. \end{cases} \tag{232}$$

On the other hand, we have

$$m_j(\mathrm{i}\beta_{\nu,m,k}) = m_j(\xi_k) = \begin{cases} 1 & \text{for } j = k,\ k \neq 1, \\ 2 & \text{for } j = k,\ k = 1, \\ 0 & \text{otherwise.} \end{cases}$$

Negative spectrum σ_- For a given bifurcation point $(\alpha_o, \beta_o, 0)$, we need to determine the negative spectrum σ_- of the operator $\mathcal{A}$ (given by (180) with $u_o = 0$). One can easily verify that the spectrum $\sigma(\mathcal{A})$ of the operator $\mathcal{A}$ is given by

$$\sigma(\mathcal{A}) = \left\{ \zeta_{m,k} := \frac{m^2 + \alpha_o \xi_k}{m^2 + 1} \colon m = 0, 1, 2, 3, \dots; k = 0, 1, \dots, 5 \right\}$$

where the isotypical multiplicity of $\zeta_{m,k}$ is the same as that of ξ_k. Consequently, we can define

$$m_i := \sum_{\mu \in \sigma_-} m_i(\mu), \quad i = 0, 1, 2, 3, 4, 5.$$

For the considered bifurcation points, the values $(m_0, m_1, m_2, m_3, m_4, m_5)$ are listed in Table 6.

Table 6
Numbers $(m_0, m_1, m_2, m_3, m_4)$ for the bifurcation points $(\alpha_{\nu,m,k}, \beta_{\nu,m,k})$

(ν, m, k)	$k=0$	$k=1$	$k=2$	$k=3$	$k=4$	$k=5$

$(4, 1, k)$	[4, 2, 3, 3, 0]	[8, 4, 6, 8, 0]	[0, 4, 0, 0, 4]	[5, 2, 4, 5, 0]	[4, 2, 3, 4, 0]	[0, 3, 0, 0, 4]
$(1, 2, k)$	[0, 2, 0, 0, 2]	[0, 4, 0, 0, 5]	[4, 2, 3, 3, 0]	[0, 3, 0, 0, 3]	[0, 2, 0, 0, 2]	[4, 2, 3, 3, 0]
$(2, 2, k)$	[3, 1, 2, 3, 0]	[7, 3, 5, 7, 0]	[0, 3, 0, 0, 3]	[4, 2, 3, 4, 0]	[3, 2, 2, 3, 0]	[0, 3, 0, 0, 3]
$(3, 2, k)$	[0, 2, 0, 0, 3]	[0, 6, 0, 0, 6]	[5, 0, 4, 5, 0]	[0, 4, 0, 0, 4]	[0, 3, 0, 0, 3]	[5, 2, 3, 4, 0]
$(4, 2, k)$	[4, 2, 3, 4, 0]	[8, 4, 7, 8, 0]	[0, 4, 0, 0, 4]	[6, 3, 4, 5, 0]	[5, 2, 3, 4, 0]	[0, 4, 0, 0, 4]
$(1, 3, k)$	[0, 3, 0, 0, 3]	[0, 6, 0, 0, 6]	[5, 2, 4, 5, 0]	[0, 4, 0, 0, 4]	[0, 3, 0, 0, 3]	[5, 2, 3, 4, 0]
$(2, 3, 0)$	[4, 2, 3, 3, 0]	[8, 4, 6, 8, 0]	[0, 4, 0, 0, 4]	[5, 2, 4, 5, 0]	[4, 2, 3, 4, 0]	[0, 4, 0, 0, 4]
$(3, 3, 0)$	[0, 3, 0, 0, 3]	[0, 7, 0, 0, 7]	[6, 3, 4, 5, 0]	[0, 4, 0, 0, 4]	[0, 3, 0, 0, 3]	[6, 2, 4, 5, 0]
$(4, 3, 0)$	[4, 2, 3, 4, 0]	[8, 4, 7, 8, 0]	[0, 4, 0, 0, 5]	[6, 3, 4, 6, 0]	[5, 2, 3, 4, 0]	[0, 4, 0, 0, 4]

Consequently, in order to compute the value of the local bifurcation invariant $\omega(\alpha_{\nu,m,k}, \beta_{\nu,m,k})$ we need to use the following Maple© procedure

$$\text{showdegree[A5]}(\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \mathfrak{t}_0, \mathfrak{t}_1, \mathfrak{t}_2, \mathfrak{t}_3, \mathfrak{t}_4, \mathfrak{t}_5)$$

where $\varepsilon_i = m_i \bmod 2$, and (since only ξ_2 and ξ_5 are negative)

$$\mathfrak{t}_j := \mathfrak{t}_j(\alpha_{\nu,m,k}, \beta_{\nu,m,k}) = \begin{cases} (-1)^\nu & \text{if } j=k,\ k=0,3,4, \\ (-1)^{\nu+1} & \text{if } j=k,\ k=2,5, \\ (-1)^\nu 2 & \text{if } j=k,\ k=1. \end{cases}$$

Preparation of input data for the Maple© routines Based on the above computations we are now in a position to prepare the input data for the Maple© routines in order to evaluate (for selected bifurcation points $(\alpha_{\nu,m,k}, \beta_{\nu,m,k}, 0)$) the exact value of the bifurcation invariant

$$\begin{aligned} &\omega(\alpha_{\nu,m,k}, \beta_{\nu,m,k}) \\ &\quad = \texttt{showdegree[A5]}(\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \mathfrak{t}_0, \mathfrak{t}_1, \mathfrak{t}_2, \mathfrak{t}_3, \mathfrak{t}_4, \mathfrak{t}_5), \end{aligned}$$

which is presented in Table 7.

Table of results In Table 8, we present the classification of the A_5-symmetric Hopf bifurcation in (216) for selected bifurcation points $(\alpha_{\nu,m,k}, \beta_{\nu,m,k}, 0)$.

Table 7
Input data $(\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4, \varepsilon_5, \mathfrak{t}_0, \mathfrak{t}_1, \mathfrak{t}_2, \mathfrak{t}_3, \mathfrak{t}_4, \mathfrak{t}_5)$ for selected bifurcation points $(\alpha_{\nu,m,k}, \beta_{\nu,m,k})$

$(\alpha_{\nu,m,k}, \beta_{\nu,m,k})$	(ν, m, k)	$\varepsilon_0, \varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4$	$\mathfrak{t}_0, \mathfrak{t}_1, \mathfrak{t}_2, \mathfrak{t}_3, \mathfrak{t}_4$

8.5. *Bibliographical remarks*

The model presented in Subsection 8.1 was rigorously studied in [11] . Symmetric configuration of transmission lines presented in Subsection 8.2, was analyzed in details in [15] The global bifurcation results given in Subsection 8.3 were published in [13]. For more details we refer to [19]. Similar systems of symmetric DEs and FDEs were also considered in [67,65,66,68,92,94,95,129,140,145,146,148]. In the non-symmetric case, local and global Hopf bifurcation problems in FDEs were studied in [36,110,111,124,125,122,123].

The results presented in Subsection 8.4 were taken from [16]. For population ecology background, which was used in this section, we refer to [73,136,56,70]. An equation, sim-

ilar to (215) (for a single species in one dimensional space), was also studied in [145] for the stability property of the periodic solutions bifurcating from 0.

Appendix A

Dihedral group D_N

Represent the dihedral group D_N of order $2N$ as the group of rotations $1, \xi, \xi^2, \ldots, \xi^{N-1}$ of the complex plane (where ξ is the multiplication by $e^{\frac{2\pi i}{N}}$) plus the reflections κ, $\kappa\xi$, $\kappa\xi^2, \ldots, \kappa\xi^{N-1}$ with κ being the operator of complex conjugation described by the matrix $\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$.

Let us introduce some special subgroups of D_N and of $D_N \times S^1$. For a positive integer k with $k|N$, and $\gamma := e^{\frac{2\pi i}{k}}$, we have:

(i) the subgroups $D_k = \{1, \gamma, \gamma^2, \ldots, \gamma^{k-1}, \kappa, \kappa\gamma, \ldots, \kappa\gamma^{k-1}\}$ and their isomorphic copies

$$D_{k,j} = \{1, \gamma, \gamma^2, \ldots, \gamma^{k-1}, \kappa\xi^j, \kappa\xi^j\gamma, \ldots, \kappa\xi^j\gamma^{k-1}\} \subset D_N,$$

$j = 0, 1, \ldots, \frac{N}{k} - 1$, which are all conjugate if $\frac{N}{k}$ is odd, but split into two conjugacy classes (D_k) and $(\widetilde{D}_k)$, where $\widetilde{D}_k := D_{k,1}$, if $\frac{N}{k}$ is even;

(ii) the twisted subgroups of $\mathbb{Z}_k = \{1, \gamma, \gamma^2, \ldots, \gamma^{k-1}\}$, which are the subgroups

$$\mathbb{Z}_k^{t_r} := \{(1, 1), (\gamma, \gamma^r), (\gamma^2, \gamma^{2r}), \ldots, (\gamma^{k-1}, \gamma^{(k-1)r})\},$$

with $r \in \{0, 1, \dots, k-1\}$. Obviously, for $0 < r < \frac{k}{2}$, $\kappa \mathbb{Z}_k^{t_r} \kappa = \mathbb{Z}_k^{t_{k-r}}$, i.e. $\mathbb{Z}_k^{t_r}$ and $\mathbb{Z}_k^{t_{k-r}}$ are conjugate;

(iii) the twisted subgroups

$$D_k^z = \big\{(1,1), (\gamma,1), \dots, (\gamma^{k-1},1), (\kappa,-1), (\kappa\gamma,-1), \dots, (\kappa\gamma^{k-1},-1)\big\},$$

of D_k (and similarly for the $D_{k,j}$ and, in particular, for $\widetilde{D}_k$);

(iv) another set of twisted subgroups in the case $k = 2m$:

First,

$$D_{2m}^d = \big\{(1,1), (\gamma,-1), (\gamma^2,1), \dots, (\gamma^{k-1},-1), (\kappa,1), (\kappa\gamma,-1), \dots, \\ (\kappa\gamma^{k-1},-1)\big\}$$

and similarly

$$\widetilde{D}_{2m}^d = \big\{(1,1), (\gamma,-1), (\gamma^2,1), \dots, (\gamma^{k-1},-1), (\kappa\xi,1), (\kappa\xi\gamma,-1), \\ \dots, (\kappa\xi\gamma^{k-1},-1)\big\}.$$

If $\frac{N}{2m} =: l$ is even, then

$$\begin{aligned} D_{2m}^{\hat{d}} &:= \big\{(1,1), (\gamma,-1), (\gamma^2,1), \dots, (\gamma^{k-1},-1), (\kappa,-1), (\kappa\gamma,1), \\ &\qquad \dots, (\kappa\gamma^{k-1},1)\big\} \\ &= \mathrm{e}^{-\frac{2\pi \mathrm{i}}{4m}} D_{2m}^d \mathrm{e}^{\frac{2\pi \mathrm{i}}{4m}} = \xi^{-\frac{l}{2}} D_{2m}^d \xi^{\frac{l}{2}}, \end{aligned}$$

i.e. $D_{2m}^{\hat{d}}$ and D_{2m}^d are conjugate, but not in the case of $l := \frac{N}{2m}$ being odd. Observe that for $\frac{N}{2m} \in \{3, 5, 7, \dots\}$,

$$\xi^{-\frac{1}{2}(\frac{N}{2m}+1)} D_{2m}^{\hat{d}} \xi^{\frac{1}{2}(\frac{N}{2m}+1)} = \widetilde{D}_{2m}^d, \quad \text{i.e.} \quad D_{2m}^{\hat{d}} \sim \widetilde{D}_{2m}^d;$$

(v) the subgroup, for $k = 2m$,

$$\mathbb{Z}_{2m}^d := \mathbb{Z}_{2m}^{t_m} = \big\{(1,1), (\gamma,-1), (\gamma^2,1), \dots, (\gamma^{2m-1},-1)\big\}.$$

In the case $m = 1$ we will write $\mathbb{Z}_2^-$ instead of $\mathbb{Z}_2^d$.

Irreducible representations of dihedral groups

Let us describe the list of all real irreducible representations of D_n.

(a0) Clearly, there is a one-dimensional trivial representation $\mathcal{V}_0$. In this case,

$$\deg_{\mathcal{V}_0} = -(D_n).$$

(a1) For every integer number $1 \leqslant j < n/2$, there is an orthogonal representation $\mathcal{V}_j$ of D_n on $\mathbb{C}$ given by

$$\gamma z := \gamma^j \cdot z, \quad \text{for } \gamma \in \mathbb{Z}_n \text{ and } z \in \mathbb{C};$$
$$\kappa z := \bar{z},$$

where $\gamma^j \cdot z$ denotes the usual complex multiplication. Put

$$h := \gcd(j, n) \quad \text{and} \quad m := n/h. \tag{233}$$

Put $j_n := [(n+1)/2]$.

(a2) There is a representation $\mathcal{V}_{j_n}$ given by the homomorphism $c : D_n \to \mathbb{Z}_2$, such that $\ker c = \mathbb{Z}_n$.

(a3) For n even, there is an irreducible representation $\mathcal{V}_{j_n+1}$ given by $d : D_n \to \mathbb{Z}_2$ such that $\ker d = D_{n/2}$.

(a4) Also, for n even, there is an irreducible representation $\mathcal{V}_{j_n+2}$ given by $\hat{d} : D_n \to \mathbb{Z}_2$, where $\ker \hat{d} = \widetilde{D}_{n/2}$.

Icosahedral group A_5

Consider the icosahedral group $\mathbb{I}$ consisting of symmetries (preserving orientation) of a regular icosahedron. The group $\mathbb{I}$ is isomorphic to the alternating group of five elements A_5 and it has 60 elements. Let us list (nontrivial) representatives of the conjugacy classes of the subgroups in A_5:

$$\mathbb{Z}_2 = \{(1), (12)(34)\},$$
$$\mathbb{Z}_3 = \{(1), (123), (132)\},$$
$$V_4 = \{(1), (12)(34), (13)(24), (23)(14)\},$$
$$\mathbb{Z}_5 = \{(1), (12345), (13524), (14253), (15432)\},$$
$$D_3 = \{(1), (123), (132), (12)(45), (13)(45), (23)(45)\},$$
$$A_4 = \{(1), (12)(34), (13)(24), (14)(23), (123), (132), (124), (142), (134), (143), (234), (243)\},$$
$$D_5 = \{(1), (12345), (13524), (14253), (15432), (12)(35), (13)(45), (14)(23), (15)(24), (25)(34)\}.$$

We have the following list, up to conjugacy, of the twisted (one-folded) subgroups H^{φ} of $A_5 \times S^1$, where H is a subgroup of A_5, $\varphi : H \to S^1$ a group homomorphism, and $H^{\varphi} = \{(h,z) \in H \times S^1\colon\ \varphi(h) = z\}$:

$$\begin{aligned}
\mathbb{Z}_2^- &= \bigl\{\bigl((1),1\bigr), \bigl((12)(34),-1\bigr)\bigr\},\\
V_4^- &= \bigl\{\bigl((1),1\bigr), \bigl((12)(34),-1\bigr), \bigl((13)(24),-1\bigr), \bigl((23)(14),1\bigr)\bigr\},\\
\mathbb{Z}_5^{t_1} &= \bigl\{\bigl((1),1\bigr), \bigl((12345),\xi\bigr), \bigl((13524),\xi^2\bigr), \bigl((14253),\xi^3\bigr), \bigl((15432),\xi^4\bigr)\bigr\},\\
\mathbb{Z}_5^{t_2} &= \bigl\{\bigl((1),1\bigr), \bigl((12345),\xi^2\bigr), \bigl((13524),\xi^4\bigr), \bigl((14253),\xi\bigr), \bigl((15432),\xi^3\bigr)\bigr\},\\
\mathbb{Z}_3^{t} &= \bigl\{\bigl((1),1\bigr), \bigl((123),\gamma\bigr), \bigl((132),\gamma^2\bigr)\bigr\},\\
D_3^{z} &= \bigl\{\bigl((1),1\bigr), \bigl((123),1\bigr), \bigl((132),1\bigr), \bigl((12)(45),-1\bigr), \bigl((13)(45),-1\bigr),\\
&\qquad \bigl((23)(45),-1\bigr)\bigr\},\\
A_4^{t_1} &= \bigl\{\bigl((1),1\bigr), \bigl((12)(34),1\bigr), \bigl((13)(24),1\bigr), \bigl((14)(23),1\bigr), \bigl((123),\gamma\bigr),\\
&\qquad \bigl((132),\gamma^2\bigr), \bigl((124),\gamma^2\bigr), \bigl((142),\gamma\bigr), \bigl((134),\gamma\bigr), \bigl((143),\gamma^2\bigr),\\
&\qquad \bigl((234),\gamma^2\bigr), \bigl((243),\gamma\bigr)\bigr\},\\
A_4^{t_2} &= \bigl\{\bigl((1),1\bigr), \bigl((12)(34),1\bigr), \bigl((13)(24),1\bigr), \bigl((14)(23),1\bigr), \bigl((123),\gamma^2\bigr),\\
&\qquad \bigl((132),\gamma\bigr), \bigl((124),\gamma\bigr), \bigl((142),\gamma^2\bigr), \bigl((134),\gamma^2\bigr), \bigl((143),\gamma\bigr), \bigl((234),\gamma\bigr),\\
&\qquad \bigl((243),\gamma^2\bigr)\bigr\},\\
D_5^{z} &= \bigl\{\bigl((1),1\bigr), \bigl((12345),1\bigr), \bigl((13524),1\bigr), \bigl((14253),1\bigr), \bigl((15432),1\bigr),\\
&\qquad \bigl((12)(35),-1\bigr), \bigl((13)(45),-1\bigr), \bigl((14)(23),-1\bigr), \bigl((15)(24),-1\bigr),\\
&\qquad \bigl((25)(34),-1\bigr)\bigr\},
\end{aligned}$$

where $\xi = \mathrm{e}^{\frac{2\pi}{5}\mathrm{i}}$, $\gamma = \mathrm{e}^{\frac{2\pi\mathrm{i}}{3}}$.

Irreducible representations of A_5

There are exactly 5 irreducible representations of A_5: $\mathcal{V}_0$ – the trivial representation, $\mathcal{V}_1$ – the natural 4-dimensional representation of A_5, $\mathcal{V}_2$ – the 5-dimensional representation of A_5, and two 3-dimensional representations $\mathcal{V}_3$ and $\mathcal{V}_4$. We distinguish these two representations by their characters χ_3 and χ_4, i.e. we assume that

$$\chi_3\bigl((12345)\bigr) = \frac{1+\sqrt{5}}{2}, \qquad \chi_4\bigl((12345)\bigr) = \frac{1-\sqrt{5}}{2}.$$

Notice that all the irreducible Γ-representations considered in this appendix are of real type. Therefore, the corresponding to $\mathcal{V}_j$ irreducible $\Gamma \times S^1$-representation $\mathcal{V}_{j,l}$ can be easily constructed from the formula $\mathcal{V}_{j,l} = {}^{l}\mathcal{V}_j^c$.

1. Introduction

In the last four decades, the field of nonautonomous dynamical systems has developed from a loose collection of results and techniques into a coherent area with a recognizable and characteristic set of methods and problems. Among the more classical areas of pure and applied mathematics which it has influenced are spectral theory, control theory, bifurcation theory, functional differential equations, monotone systems, and others as well.

There is a certain amount of conceptual overlap between the fields of nonautonomous dynamical systems and stochastic dynamical systems. In the latter area, one places emphasis on the use of dynamical techniques to study stochastic differential equations. This point of view has been applied systematically and with particular success by L. Arnold and his school. It is natural to think of the two fields – nonautonomous dynamics and stochastic dynamics – as occupying complementary parts of the theory of differential equations with time-varying coefficients. It may not be unreasonable to use a term such as "random dynamics" to cover their union.

Be that as it may, the following considerations allow one to distinguish the two fields.

First of all, a nonautonomous dynamical system is frequently defined in terms of the solutions of a differential equation whose coefficients vary with time, but in a nonstochastic way. The limiting case is that of equations with periodic time dependence; however, one is also interested in equations whose coefficients satisfy Bohr almost periodicity, Birkhoff recurrence, or still weaker recurrence properties. One can express the same idea in a different way by saying that the time dependence of the coefficients exhibits randomness which is "between" periodicity and stochasticity.

A second distinction occurs on the methodological level. Ergodic techniques, for example the Oseledets theory, have an important place in the study of stochastic dynamical systems. This is true in the study of the nonautonomous ones, as well. However, in the latter area, techniques of topological dynamics are of equal importance. There is a reason for this. Namely, a Bebutov-type construction can often be applied to the right-hand side of a nonautonomous differential equation, giving rise to a compact hull. The solutions of the original equation together with those of the equations in the hull then form a continuous dynamical system. Of course one has a vast array of results available to study this system; they are associated with the names of Bronstein, Ellis, Furstenberg, Sell, and many other researchers. These results, however, cannot usually be applied to a stochastic dynamical system since, for such a system, the equivalent of the "hull" has only a measurable structure (but see [69]).

We will explain the Bebutov construction later on. Before doing so, we make some simple observations concerning *autonomous* differential equations, with the purpose of putting the succeeding discussion into perspective.

It is well known that the solutions of an autonomous differential equation

$$x' = f(x), \quad x \in \mathbb{R}^n \tag{1.1}$$

define a local flow on $\mathbb{R}^n$ if f is Lipschitz continuous. They define a global flow if f is complete; that is, if for each $x_0 \in \mathbb{R}^n$, the solution $x(t)$ of (1.1) satisfying $x(0) = x_0$ is defined on the whole real line $-\infty < t < \infty$. This simple observation is very useful if one wishes to study the asymptotic behavior of the solutions of Eq. (1.1). In particular, a coherent and articulated answer to the question "where do the solutions go?" can be given using the concepts of α- and ω-limit sets, attractors and repellers, basins of attraction/repulsion, etc.

The situation is quite different if f is time dependent: $f = f(t, x)$, $(t \in \mathbb{R}, x \in \mathbb{R}^n)$. It is of course true that, if f is T-periodic for some $T > 0$, then one can introduce the period map defined by solving

$$x' = f(t, x) \tag{1.2}$$

for initial conditions $x(0) \in \mathbb{R}^n$ and continuing them for time T. One thus obtains a discrete flow or discrete dynamical system, at least if all solutions of (1.2) exist for all $t \in \mathbb{R}$. The study of such a system is in many (but not all) ways analogous to that of the continuous dynamical system defined by the solutions of the autonomous equation (1.1).

If f is aperiodic, however, the period map is not available. The fact is that such objects as ω-limit sets do not in general provide much information about the asymptotic behavior of the solutions of (1.2). One can adjoin the equation $t' = 1$ to (1.2), thereby obtaining an autonomous equation on $\mathbb{R} \times \mathbb{R}^n$ which defines a dynamical system on that space. However, all α- and ω-limit sets are empty. Moreover, the t-recurrence properties of f are not reflected in the extended vector field. The addition of the equation $t' = 1$ to (1.2) therefore is unsatisfying if one wishes to use dynamical methods to study Eq. (1.2).

Fortunately, it turns out that very often a simple and direct construction – first studied systematically by Bebutov ([12], also [143]) – permits one to use the full panoply of methods of dynamical systems theory to study the solutions of a nonautonomous differential equation (1.2). See, e.g., [33,94,143]. Let us illustrate the Bebutov construction in the case of a linear system

$$x' = A(t)x, \quad x \in \mathbb{R}^n, t \in \mathbb{R} \tag{1.3}$$

where A is a bounded, uniformly continuous function with values in the space $\mathbb{M}_n$ of $n \times n$ real matrices. Introduce the space $\mathcal{C} = C(\mathbb{R}, \mathbb{M}_n) = \{C : \mathbb{R} \to \mathbb{M}_n \mid C$ is continuous and bounded$\}$, equipped with the topology of uniform convergence on compact subsets of $\mathbb{R}$. For each $t \in \mathbb{R}$, let $\tau_t : \mathcal{C} \to \mathcal{C}$ be the translation:

$$\tau_t(C)(\cdot) = C(t + \cdot) \quad (C \in \mathcal{C}).$$

Then $\{\tau_t \mid t \in \mathbb{R}\}$ defines a flow on $\mathcal{C}$. That is $\tau_0 = \mathrm{id}y$; $\tau_t \circ \tau_s = \tau_{t+s}$ for all $t, \in \mathbb{R}$; and $\tau : \mathcal{C} \times \mathbb{R} \to \mathcal{C}$: $\tau(C, t) = \tau_t(C)$ is continuous. We call $\{\tau_t\}$ the *Bebutov flow* on $\mathcal{C}$.

Now view $A(\cdot)$ as an element of $\mathcal{C}$. Let $\Omega = \mathrm{cls}\{\tau_t(A) \mid t \in \mathbb{R}\}$. Then Ω is compact since A is uniformly continuous. Let us outline a proof of this fact. Let $\{t_n\} \subset \mathbb{R}$ be a sequence. We first show that the sequence $\{\tau_{t_n}(A)\}$ contains a subsequence which converges in $\mathcal{C}$. For, let $k \geqslant 1$, let $I_k = [-k, k] \subset \mathbb{R}$. By the Ascoli–Arzelá theorem, there is a subsequence $t_{n_1}, \ldots, t_{n_j}, \ldots$ of $\{t_n\}$ such that $\{t_{n_j}(A)\}$ converges uniformly on I_k. We label this sequence t_j^k $(j = 1, 2, \ldots)$, then set $s_k = t_k^k$ $(k = 1, 2, \ldots)$. Clearly $\{\tau_{s_k}(A)\}$ converges in $\mathcal{C}$. If $\{\omega_n\} \subset \Omega$ is a sequence, we approximate $\omega_n \in \mathcal{C}$ by $\tau_{t_n}(A)$ for an appropriate $t_n \in \mathbb{R}$, then extract a convergent subsequence of $\{\omega_n\}$ by applying the Ascoli–Arzelá theorem and a Cantor diagonal argument to the sequence $\{\tau_{t_n}(A)\}$.

Note further that Ω admits a dense orbit. Also Ω is invariant with respect to the Bebutov flow. If $\omega \in \Omega$, then it makes sense to speak of the differential equation $x' = \omega(t)x$. A notational device is convenient. Define $\tilde{A} : \Omega \to \mathbb{M}_n$: $\tilde{A}(\omega) = \omega(0)$. Then $\tilde{A}(\tau_t(\omega)) = \omega(t)$ for all $\omega \in \Omega$, $t \in \mathbb{R}$. Moreover if we write $\omega_0 = A \in \Omega$, then $\tilde{A}(\tau_t(\omega_0)) = A(t)$, and so the differential equation $x' = \tilde{A}(\tau_t(\omega_0))x$ coincides with (1.3).

Let us abuse notation and write $A : \Omega \to \mathbb{M}_n$: $A(\omega) = \omega(0)$. We consider the family of equations

$$x' = A\big(\tau_t(\omega)\big)x \quad (x \in \mathbb{R}^n, \omega \in \Omega). \tag{1.3_ω}$$

This family is indexed by the compact, Bebutov-invariant set $\Omega \subset \mathcal{C}$, and contains the initial equation (1.3) = (1.3_{ω_0}).

Let $\omega \in \Omega$, and let $\Phi_\omega(t)$ be the fundamental matrix solution of (1.3_ω). The collection $\{\Phi_\omega(t) \mid \omega \in \Omega\}$ defines a map $\Phi : \Omega \times \mathbb{R} \to \mathrm{GL}(n, \mathbb{R}) : (\omega, t) \mapsto \Phi_\omega(t)$. The map Φ is a *cocycle*; i.e., it satisfies the relation

$$\Phi_{\omega\cdot t}(s)\Phi_\omega(t) = \Phi_\omega(t+s) \quad (\omega \in \Omega; t, s \in \mathbb{R}).$$

The cocycle relation follows from uniqueness of solutions, which holds for Eqs. (1.3_ω). Now, using the cocycle relation, one verifies the following assertion.

For each $t \in \mathbb{R}$ define $\tilde{\tau} : \Omega \times \mathbb{R}^n \to \Omega \times \mathbb{R}^n$ via the formula

$$\tilde{\tau}_t(\omega, x) = \big(\tau_t(\omega), \Phi_\omega(t)x\big);$$

then $(\Omega \times \mathbb{R}^n, \{\tilde{\tau}_t\})$ is a flow. Note that the first coordinate on the right does not depend on x, and that the second coordinate on the right is linear in x.

The flow $\{\tilde{\tau}_t\}$ is a nonautonomous analogue of the one-parameter group $\{\hat{\tau}_t = \mathrm{e}^{At}\}$ generated by the linear autonomous equation $x' = Ax$. The systematic study of the flow $\{\tilde{\tau}_t\}$ on $\Omega \times \mathbb{R}^n$ has led to new insights concerning the properties of solutions of linear nonautonomous ODEs. Experience has shown that, although some problems involving linear systems (1.3) can be treated without introducing the hull Ω and the flow $\{\tilde{\tau}_t\}$, others seem to require it for effective study.

Next, consider a nonlinear nonautonomous equation (1.2). Suppose that, for each compact set $K \subset \mathbb{R}^n$, f is uniformly continuous and uniformly bounded on $\mathbb{R} \times K$. For simplicity, suppose also that f is uniformly Lipschitz on each set $\mathbb{R} \times K$, in the sense that there is a constant M_K such that

$$\big\| f(t,x) - f(t,y) \big\| \leqslant M_K \|x - y\|$$

for all $t \in \mathbb{R}, x, y \in K$.

In this case, one can carry out a Bebutov-type construction to obtain a compact, translation-invariant set $\Omega = \Omega_f$ of functions $\omega(t, x)$, each having the properties satisfied by f which are listed above. The flow is defined by $\tau_t(\omega)(\cdot, x) = \omega(\cdot + t, x)$. Furthermore, if $\omega \in \Omega, x_0 \in \mathbb{R}$, and $x(t)$ is the solution of the equation $x' = \omega(t, x)$ which satisfies $x(0) = x_0$, then the locally defined mappings given by $\tilde{\tau}_t(\omega, x_0) = (\tau_t(\omega), x(t))$ define a local flow on $\Omega \times \mathbb{R}^n$. This flow is global if all solutions of all equations $x' = \omega(t, x)$ exist on $(-\infty, \infty)$. In this case, one obtains a dynamical system on $\Omega \times \mathbb{R}^n$, the behavior of whose orbits reflects the behavior of the solutions of the various equations $x' = \omega(t, x)$, and also reflects the t-recurrence properties of f. These last properties are encoded in the translation flow $\{\tau_t\}$ on Ω.

One can now systematically apply the methods of topological dynamics, ergodic theory etc. to study the solutions of the family of equations $x' = \omega(t, x)$ $(\omega \in \Omega)$. This procedure not infrequently leads to insights concerning the original equation which might not otherwise have come to light. Of course the remark made above for linear systems applies to the nonlinear ones, as well.

Constructions of Bebutov-type can also be carried out for wide classes of parabolic or hyperbolic partial differential equations and for functional differential equations with time-varying coefficients. As a consequence, one can effectively use “dynamical” methods to study such equations. See, e.g., [4,119,124,125] for examples illustrating this approach. We will not give more details here because our attention in this paper will be focused on linear ordinary differential equations, usually in dimension 2.

We turn to an outline of the contents of this paper. Consider the linear, nonautonomous, two-dimensional differential equation

$$x' = A(t)x, \quad x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ t \in \mathbb{R}. \tag{1.4}$$

We are interested in functions $A(\cdot)$ which depend aperiodically on time; on the other hand we will impose certain recurrence properties on A. In fact, we will always assume that A is stationary and ergodic in a sense to be defined later (Section 2). Often we will assume that A is a Birkhoff recurrent function of t, or even that A is Bohr almost periodic. Even under such restrictive hypotheses, we will see that the solutions of (1.4) exhibit remarkable properties which have no analogues in the case of periodic systems.

In Section 3, we will study the minimal subsets of the projective flow defined by Eq. (1.4). We will always assume that $A(\cdot)$ is Birkhoff recurrent and usually that it is Bohr almost periodic. A characterization of the minimal subsets of the projective flow constitutes one approach to generalizing to recurrent systems (1.4) the standard Floquet theory for periodic linear systems.

In more detail, let $\mathcal{C} = C(\mathbb{R}, \mathbb{M}_2)$ with the compact-open topology, and let $\Omega \subset \mathcal{C}$ be the result of the Bebutov construction applied to $A(\cdot)$. By carrying out the various steps discussed previously, we obtain a family of differential systems

$$x' = A\big(\tau_t(\omega)\big)x; \tag{1.4$_\omega$}$$

the original equation (1.4) is in this family.

Let $\mathbb{P}$ be the set of lines through the origin in $\mathbb{R}^2$. Thus $\mathbb{P}$ is the one-dimensional real projective space and is topologically a circle. The family (1.4$_\omega$) induces a flow on $\Sigma =$

$\Omega \times \mathbb{P}$, in the following way. Let $\Phi_\omega(t)$ be the fundamental matrix solution of (1.4_ω). For each $t \in \mathbb{R}$, set

$$\hat{\tau}_t(\omega, l) = \big(\tau_t(\omega), \Phi_\omega(t)l\big) \quad (\omega \in \Omega, l \in \mathbb{P}).$$

It is easy to verify that $(\Sigma, \{\hat{\tau}_t\})$ is indeed a flow. We set the goal of classifying those compact, nonempty, $\{\hat{\tau}_t\}$ – invariant subsets $M \subset \Sigma$ which are minimal in the sense that, for each $m \in M$, the orbit $\{\hat{\tau}_t(m) \mid t \in \mathbb{R}\}$ is dense in M.

Such minimal sets are quite easy to understand if A is periodic. In the case when A is Bohr almost periodic, however, a minimal subset $M \subset \Sigma$ may have properties quite unlike those occurring when A is periodic. In the recurrent case, there are even more possibilities for M. To simplify the discussion, we will assume, with few exceptions, that A is almost periodic.

One striking phenomenon which may be present in the projective flow of an almost periodic family (1.4_ω) is that of almost automorphy in the sense of Bochner and Veech [20,150,151]. We will see that various types of almost automorphic, non-almost periodic minimal sets can be realized as invariant subsets of the projective flow defined by an almost periodic family (1.4_ω). Moreover, we will see that these almost automorphic minimal sets illustrate in a concrete way such phenomena as Marcus–Moore disconjugacy, unbounded mean motion, and strange nonchaotic attractors. Examples illustrating these phenomena are of “M-V type”, where the letters indicate the names of Millionscikov and Vinograd. They constructed the first examples of almost periodic families (1.4_ω) containing equations which are not almost reducible [108,152]. It later turned out that these and related examples give rise to almost automorphic subsets of Σ as mentioned above.

We note further that the projective flow $(\Sigma, \{\hat{\tau}_t\})$ of an almost periodic family (1.4_ω) may contain an almost automorphic minimal set which is not of M-V type. For instance, there are families (1.4_ω) for which the Favard separation property is violated and for which each Eq. (1.4_ω) admits a bounded solution. In these circumstances, it may happen that Σ contains an almost automorphic, non-almost periodic minimal set M; for reasons which we will discuss, M cannot be of M-V type. Examples illustrating this phenomenon were constructed in [158] and, later and independently, in [73]. The phenomenon itself was nicely clarified by Ortega and Tarallo [126].

There are other classes of almost periodic families (1.4_ω) whose projective flows admit minimal sets with no analogue in the periodic case. For example, Σ may admit a unique “invariant two-sheet”. Examples of this sort were predicted in [83] and were written down in [88,123].

Furthermore, there are situations in which the projective flow Σ is itself minimal but is quite unlike those arising when Σ is minimal and A is periodic (these last are all of Kronecker type). We will consider several classes of examples. One consists of families (1.4_ω) for which Σ is minimal, uniquely ergodic, and is a proximal extension of Ω ([61], also [87]). Another class is illustrated by a recent example of Bjerklov [13,14], for which Σ is minimal and the family (1.4_ω) is weakly hyperbolic. Such examples exhibit the property of “Li–Yorke chaos”. See [17] for more information on this topic.

We close this introductory discussion of the contents of Section 3 by noting that the measure-theoretic (ergodic) structure of the projective flow of Eqs. (1.4_ω) is more completely understood than is the topologico-dynamical structure. See [122,121] for a discussion and classification of the ergodic measures of the projective flow when $n = 2$. See also [9] and references therein for a complete theory of the ergodic measures of the projective flow for n-dimensional linear systems.

In Section 4, we discuss some recent developments in the spectral theory and inverse spectral theory of the classical Sturm–Liouville operator. The material reviewed here is found in the Ph.D. thesis of one of us [157] and in [96,95]. The methods of nonautonomous differential equations are systematically exploited both in the formulation of and in the proofs of the results we consider. Other techniques, in particular certain constructions from the classical theory of algebraic curves, are also found to be very useful.

The theory we present is motivated in part by the progress in the inverse spectral theory of the one-dimensional Schrödinger operator which took place in the 1970s. In fact, it was discovered that there are basic and nonobvious relations between the inverse spectral theory of the Schrödinger operator, the theory of algebraic curves, and the solutions of a certain hierarchy of nonlinear partial differential equations. One of the equations of this hierarchy is the K-dV (Korteweg–de Vries) equation

$$\frac{\partial u}{\partial t} = 3u\frac{\partial u}{\partial x} - \frac{1}{2}\frac{\partial^3 u}{\partial x^3}$$

of shallow water-wave theory.

It turns out that the inverse spectral theory of the Sturm–Liouville operator also can be studied using the theory of algebraic curves, in particular certain facts concerning generalized Jacobians. To work out the relation between these a priori separate fields, it is convenient to first develop certain aspects of the *direct* spectral theory of the Sturm–Liouville operator. To this end, one uses facts from the theory of nonautonomous differential equations. Among the “nonautonomous” facts which are found useful are the following:

- The equivalence between the resolvent of a Sturm–Liouville operator and the existence of an exponential dichotomy for the associated nonautonomous linear system.
- The relation between the spectrum of a Sturm–Liouville operator and the rotation number of the associated nonautonomous linear system.
- The Kotani theory for Sturm–Liouville type operators.

We will discuss these matters. We will in addition give a brief discussion of the Gilbert–Pearson theory [60] in the context of the Sturm–Liouville operator. This theory has been found to be of basic importance in the study of the one-dimensional Schrödinger operator and we think it is important to indicate how the Gilbert–Pearson theory can be extended to the more general Sturm–Liouville operator.

Our inverse spectral theory takes these and other facts as a starting point. Making use of the Weyl m-functions, one then can make a connection between a Sturm–Liouville operator having certain spectral properties, and a generalized Jacobian. One is able to give a concrete description of the operators having these spectral properties. We will discuss all these matters in Section 4.

In analogy to the relation between the Schrödinger operator and the K-dV equation, there is a close connection between the special Sturm–Liouville operator defined by the equation

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+1\right)\varphi = Ey(x)\varphi$$

and the Camassa–Holm equation

$$4\frac{\partial u}{\partial t} = \frac{\partial^3 u}{\partial x^2 \partial t} + 2u\frac{\partial^3 u}{\partial x^3} + 4\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2} - 24u\frac{\partial u}{\partial x}.$$

Using our methods, it is possible to work out an ample family of quasi periodic solutions of the Camassa–Holm equation and of other equations in the Camassa–Holm hierarchy. These facts are discussed in [157,156]; for earlier work see [2,3,58]. For reasons of space we will not take up this theme in the present paper.

In the final Section 5 of this paper, we consider the following basic question. Let $(\Omega,\mathbb{R})$ be a fixed minimal flow. Let $\mathrm{sl}(2,\mathbb{R})$ be the set of all 2×2 real matrices with trace zero. Let $\mathcal{C}_0 = C(\Omega, \mathrm{sl}(2,\mathbb{R}))$ be the set of continuous functions $A:\Omega\to \mathrm{sl}(2,\mathbb{R})$ with the uniform topology induced by some fixed norm on $\mathrm{sl}(2,\mathbb{R})$. Each $A\in\mathcal{C}_0$ defines a family of two-dimensional differential systems of type (1.4_ω):

$$x' = A\big(\tau_t(\omega)\big)x, \quad x\in\mathbb{R}^2$$

where $\operatorname{tr} A(\cdot) = 0$. We ask "how many" matrix functions $A(\cdot)$ give rise to a family (1.4_ω) which exhibits an exponential dichotomy. In particular, we ask if the set of $\mathrm{sl}(2,\mathbb{R})$-valued functions $\{A\}$ for which the family (1.4_ω) has an exponential dichotomy is open and dense in $\mathcal{C}_0$.

Related questions have been considered by Millionscikov [109], Novikov [118], Cong [116,117] and many other authors. We will not give an encyclopedia of the results which have been obtained. Rather, we will consider in some detail a particular result concerning quasi-periodic minimal flows, in the C^0-category.

It is known that, for certain minimal flows $(\Omega,\mathbb{R})$ with compact metric phase space Ω, the set $\mathcal{C}_{\mathrm{ED}} = \{A\in\mathcal{C}_0 \mid \text{the family } (1.4_\omega) \text{ admits an exponential dichotomy}\}$ is *not* dense in $\mathcal{C}_0$. In fact, this is true if Ω is the circle and the flow $\{\tau_t\}$ is defined by a rigid rotation; this case occurs exactly when (1.4_ω) is a family of periodic equations with fixed period and the coefficient matrices are related one to another by translations. It also occurs whenever the image of the so-called Schwarzmann homomorphism is isomorphic to $\{0\}$ or $\mathbb{Z}$. This condition in ensured if the first integer Čech cohomology group $H^1(\Omega,\mathbb{Z})$ is, modulo torsion, equal to $\{0\}$ or $\mathbb{Z}$.

However, if Ω is the phase space of a nonperiodic, almost periodic minimal flow, then the image of the Schwarzmann homeomorphism is dense in $\mathbb{R}$ (it coincides with the so-called frequency module $\mathcal{M}$ of $(\Omega,\mathbb{R})$). In this case, the above criterion breaks down. If $(\Omega,\mathbb{R})$ is a "limit-periodic" flow, then it can be shown that $\mathcal{C}_{\mathrm{ED}}\subset\mathcal{C}_0$ is open and dense. This is not a completely straightforward matter, but arguments of Moser [110] can be adapted to do the job.

In the case when $(\Omega, \mathbb{R})$ is quasi-periodic – that is, when Ω is a k-dimensional torus and the flow is determined by a Kronecker winding – we consider the question as to whether $\mathcal{C}_{\mathrm{ED}}$ is dense in $\mathcal{C}_0$ (we note that $\mathcal{C}_{\mathrm{ED}}$ is open in $\mathcal{C}_0$ by standard perturbation results for exponential dichotomies; see, e.g., [29]). We will discuss a result to the effect that, if the Kronecker winding is defined by a Liouville frequency vector, then $\mathcal{C}_{\mathrm{ED}}$ is indeed dense in $\mathcal{C}_0$. This result is proved using methods worked out in [77,44,50].

This result can be viewed as included in a line of research which aims at determining the nature of the set of elements $A \in \mathcal{C}_0$ for which the family (1.4_ω) has a positive Lyapunov exponent. See, e.g., [117,100,15], and for definitive information [19]. We note, however, that positivity of the Lyapunov exponent is much weaker than the dichotomy property.

On the other hand, the result we discuss should be viewed as in some sense orthogonal to the impressive body of theorems worked out in, e.g., [98,39,102,135], and papers by other authors. These theorems concern the case when A is an analytic (or at least highly regular) function on the torus $\Omega = \mathbb{T}^k$, and the frequency vector satisfies a Diophantine condition. Several of these results consist of statements to the following effect: in a suitable parameterized family of analytic quasi-periodic differential systems with Diophantine frequency vector, there is a measure-theoretically large set of parameter values for which the system is reducible. That is, there is an analytic quasi-periodic change of variables $x = B(\omega \cdot t)y$ such that $x' = A(\omega \cdot t)x$ is transformed into $y' = A_0 y$ where A_0 is a constant matrix. Interestingly enough, there is often a topologically large set of parameter values for which reducibility does *not* hold. Instead, an almost reducibility property holds; moreover the projective flow corresponding to such an almost reducible system seems to have interesting properties.

Our results concerning density of $\mathcal{C}_{\mathrm{ED}} \subset \mathcal{C}_0$ would appear to break down when one passes from the C^0-category to the C^1-category, at least when $k \geqslant 3$. (Our methods may produce a density result in the C^r-category if r is less than 1.) The question of C^1-density of the dichotomy property (for any kind of frequency vector, Liouville or Diophantine or “other”) has not been clarified, and only nondefinitive indications concerning the real facts of the case are at this point available [23,26,30]. We mention that, very recently, A. Avila, J. Bochi and D. Damanik have proved the density result for all frequencies in the C^0 category. Their methods seem specific to this category, though they can also deal with certain non-almost periodic base flows. We thank Prof. David Damanik for this information.

We finish the introduction by listing some notation which will be used in this paper.

If $k \geqslant 1$, let $\mathbb{T}^k = \mathbb{R}^k/\mathbb{Z}^k$ denote the standard k-torus. Thus $\mathbb{T}^1$ is the circle, which can be identified with $\{\mathrm{e}^{2\pi \mathrm{i}\psi} \mid 0 \leqslant \psi < 1\}$.

We use $|\cdot|$ to indicate all norms which arise, and $\langle , \rangle$ to indicate all inner products.

2. Preliminaries

We review basic concepts and fix notation which will be used in the succeeding sections.

Let us first recall the definition of a (continuous, real) *flow*. Let Ω be a metric space. For each $t \in \mathbb{R}$, let $\tau_t : \Omega \to \Omega$ be a homeomorphism. Suppose that the following conditions are satisfied:

- $\tau_0(\omega) = \omega$, for all $\omega \in \Omega$;

- $\tau_{t+s}(\omega) = \tau_t \circ \tau_s(\omega)$ for all $t, s \in \mathbb{R}$, $\omega \in \Omega$;
- the map $\tau : \Omega \times \mathbb{R} \to \Omega : (\omega, t) \mapsto \tau_t(\omega)$ is continuous.

We call the pair $(\Omega, \{\tau_t\})$ a *flow* or *dynamical system* on Ω. We will also use the notation $(\Omega, \mathbb{R})$ to denote a flow, or Ω resp. $\{\tau_t\}$ if there is no doubt concerning the identity of $\{\tau_t\}$ resp. Ω. We will often write $\omega \cdot t$ in place of $\tau_t(\omega)$.

Here is some standard terminology concerning flows. If $\omega \in \Omega$, then the *orbit* through ω is $\{\omega \cdot t \mid t \in \mathbb{R}\}$. If $\Omega_* \subset \Omega$, then Ω_* is *invariant* if for every $\omega \in \Omega_*$, the orbit through ω is contained in Ω_*. Let $(\tilde{\Omega}, \{\tilde{\tau}_t\})$ be another flow. A continuous map $\pi : \tilde{\Omega} \to \Omega$ is a *flow homomorphism* if $\pi \circ \tilde{\tau}_t = \tau_t \circ \pi$ for all $t \in \mathbb{R}$. If π is also homeomorphism of $\tilde{\Omega}$ onto Ω, then π is a *flow isomorphism*.

Some flows of interest to us arise via the Bebutov construction, which we described in the Introduction. We repeat it briefly. Let $n \geqslant 1$, and let $\mathcal{C} = \{C\colon \mathbb{R} \to \mathbb{M}_n \mid C \text{is continuous and bounded}\}$. Endow $\mathcal{C}$ with the compact-open topology. For each $t \in \mathbb{R}$ and $C \in \mathcal{C}$, set $\tau_t(C)(\cdot) = C(t + \cdot)$; then τ_t is the t-translation. Then $(\mathcal{C}, \{\tau_t\})$ is a flow. If $A \in \mathcal{C}$ is uniformly continuous, define $\Omega = \operatorname{cls}\{\tau_t(A) \mid t \in \mathbb{R}\}$. Then Ω is compact and is invariant with respect to the Bebutov flow $\{\tau_t\}$. We call Ω the *hull* of A. As we pointed out in the Introduction, the map $\tilde{A} : \Omega \to \mathbb{M}_n\colon \tilde{A}(\omega) = \omega(0)$ is continuous and has the property that, if $\omega_0 = A$, then $\tilde{A}(\omega_0 \cdot t) = A(t)$ for all $t \in \mathbb{R}$. In this case it is convenient to abuse notation and write A instead of $\tilde{A}$.

Certain specific types of flow will be important in what follows; we review the relevant definitions. Let Ω be a *compact* metric space, and let $(\Omega, \{\tau_t\})$ be a flow.

First of all, the flow $(\Omega, \{\tau_t\})$ is called *minimal* or *Birkhoff recurrent* if for each $\omega \in \Omega$, the orbit $\{\omega \cdot t \mid t \in \mathbb{R}\}$ is dense in Ω. If Ω is the hull of a uniformly continuous function $A : \mathbb{R} \to \mathbb{M}_n$, then Ω is minimal if and only if A satisfies the Birkhoff recurrence condition, namely if to each compact set $K \subset \mathbb{R}$ and each $\varepsilon > 0$ there corresponds a relatively dense set $\{t_k \mid k \in \mathbb{Z}\} \subset \mathbb{R}$ such that, if $k \in \mathbb{Z}$, then $|A(t + t_k) - A(t)| \leqslant \varepsilon$ for all $t \in K$.

A special class of minimal flows is determined by those which are *Bohr almost periodic* or simply *almost periodic*. By definition, a flow $(\Omega, \mathbb{R})$ satisfies this condition if it is minimal and if there is a metric d on Ω (which is compatible with the topology on Ω) such that, if $\omega_1, \omega_2 \in \Omega$, then $d(\omega_1 \cdot t, \omega_2 \cdot t) = d(\omega_1, \omega_2)$ for all $t \in \mathbb{R}$. If Ω is the hull of a uniformly continuous function $A \in \mathcal{C}$, then $(\Omega, \mathbb{R})$ is Bohr almost periodic if and only if for each $\varepsilon > 0$ there is a relatively dense set $\{t_k \mid k \in \mathbb{Z}\}$ such that, if $k \in \mathbb{Z}$, then $|A(t + t_k) - A(t)| \leqslant \varepsilon$ for all $t \in \mathbb{R}$. One sometimes calls $\{t_k\}$ a set of almost periods of A. See, e.g., [5,21,54].

It turns out that, if $(\Omega, \mathbb{R})$ is minimal and Bohr almost periodic, then Ω may be given the structure of a compact Abelian topological group with dense subgroup $\mathbb{R}$ in such a way that the group structure and the flow structure are compatible. In fact, if $\omega_0 \in \Omega$ and $t_1, t_2 \in \mathbb{R}$, define $(\omega_0 \cdot t_1) * (\omega_0 \cdot t_2) = \omega_0 \cdot (t_1 + t_2)$. It is an exercise to show that $*$ extends to a group operation on Ω with the stated properties. Moreover ω_0 is the identity with respect to this group structure.

To each minimal almost periodic flow $(\Omega, \mathbb{R})$ there corresponds the so-called frequency module $\mathcal{M} = \mathcal{M}_\Omega$. This object is constructed in the following way. View Ω as a compact Abelian topological group with dense subgroup $\mathbb{R}$. Let $\hat{\Omega}$ be the group of continuous homomorphisms (*characters*) $\chi : \Omega \to \mathbb{T}^1$. Since $\mathbb{R} \subset \Omega$ is a dense subgroup, a character χ is determined by its restriction $\chi_{\mathbb{R}}$ to $\mathbb{R}$, and this restriction has the form $\chi_{\mathbb{R}}(t) = e^{2\pi i\lambda t}$ for some $\lambda \in \mathbb{R}$. The smallest $\mathbb{Z}$-submodule of $\mathbb{R}$ containing all the numbers λ arising in the this way is the *frequency module* of Ω. Due to the fact that Ω is a compact metric Abelian group, the frequency module is a countable subgroup of $\mathbb{R}$.

We mention the following examples. Let $\Omega = \mathbb{T}^k$ be the k-torus. Let $\gamma_1, \dots \gamma_k$ be real numbers which are independent over the rational field $\mathbb{Q}$. If $\omega \in \Omega$, write $\omega = (\exp 2\pi \mathrm{i}\psi_1, \dots, \exp 2\pi \mathrm{i}\psi_k)$, then define for each $t \in \mathbb{R}$

$$\tau_t(\omega) = \bigl(\exp 2\pi \mathrm{i}(\psi_1 + \gamma_1 t), \dots, \exp 2\pi \mathrm{i}(\psi_k + \gamma_k t)\bigr).$$

Below we will sometimes write $\psi = (\psi_1, \dots, \psi_k)$ and also write $\tau_t(\psi) = \psi + \gamma t = (\psi_1 + \gamma_1 t, \dots, \psi_k + \gamma_k t)$. One says that $(\Omega, \{\tau_t\})$ is a *quasi-periodic* flow or a *Kronecker* flow. One also speaks of a Kronecker winding. It is minimal and almost periodic. The numbers $\gamma_1, \dots, \gamma_g$ are called the *frequencies* of the flow.

Second, set $T_0 = 1, T_1 = n_1, \dots, T_k = n_k T_{k-1}, \dots$ where $n_1 > 1, \dots, n_k > 1, \dots$ are integers. Consider the subgroup $\mathcal{M}$ of $\mathbb{R}$ generated by $T_0^{-1}, \dots, T_k^{-1}, \dots$

$$\mathcal{M} = \left\{ \frac{l_0}{T_0} + \frac{l_1}{T_1} + \cdots + \frac{l_r}{T_r} \;\middle|\; r \geqslant 1; l_0, \dots, l_r \in \mathbb{Z} \right\}.$$

Then $\mathcal{M}$ is the frequency module of an almost periodic minimal flow. Such a flow is called *limit periodic*. If Ω is the hull of an almost periodic function $A : \mathbb{R} \to \mathbb{M}_n$, then $(\Omega, \mathbb{R})$ is limit periodic if and only if A is the uniform limit of a sequence of periodic functions.

Still another type of flow is distinguished by the property of *almost automorphy*. Let $(\Omega_0, \mathbb{R})$ be an almost periodic minimal flow. Let $(\Omega, \mathbb{R})$ be another minimal flow, and let $\pi : \Omega \to \Omega_0$ be a flow homomorphism. Note that π is necessarily surjective since Ω_0 is minimal. Suppose that there is a point $\omega_0 \in \Omega_0$ such that the inverse image $\pi^{-1}(\omega_0)$ reduces to a single point in Ω. Then $(\Omega, \mathbb{R})$ is called an almost automorphic extension of $(\Omega_0, \mathbb{R})$, or an *almost automorphic* flow. If Ω is the hull of an uniformly continuous bounded function $A : \mathbb{R} \to \mathbb{M}_n$, then $(\Omega, \mathbb{R})$ is almost automorphic if (but not only if) the function A satisfies the Bochner condition. Namely, if $\{t_k\} \subset \mathbb{R}$ is a sequence such that $|t_k| \to \infty$ and $A(t_k + \cdot) \to A(\cdot)$ in $\mathcal{C}$, then $A(-t_k + \cdot) \to A(\cdot)$ in $\mathcal{C}$. If the Bochner condition is satisfied, then there is an almost periodic minimal flow $(\Omega_0, \mathbb{R})$ together with a flow homomorphism $\pi : \Omega \to \Omega_0$ such that $\pi^{-1}\pi(A) = \{A\}$ [151]. A function $A(\cdot)$ which satisfies the Bochner condition is said to be an *almost automorphic function*.

Almost automorphic minimal sets were studied by Veech [150,151]. See [144,145,154] for a review of their properties and a discussion of their presence in various applied situations.

Next we review some basic definitions from ergodic theory. Let Ω be a compact metric space and let $(\Omega, \{\tau_t\})$ be a flow.

A regular Borel probability measure ν on Ω is called $\{\tau_t\}$-*invariant*, or simply *invariant* if there is no doubt concerning the identity of $\{\tau_t\}$, if for each Borel subset $B \subset \Omega$ and each $t \in \mathbb{R}$, there holds $\nu(\tau_t(B)) = \nu(B)$. An invariant measure ν is called *ergodic* if it is indecomposable in the sense that, whenever $B \subset \Omega$ is a Borel set such that $\mu(\tau_t(B) \triangle B) = 0$ for all $t \in \mathbb{R}$ ($\triangle =$ symmetric difference of sets), then either $\nu(B) = 0$ or $\nu(B) = 1$.

One can show that, if Ω is a compact metric space and $(\Omega, \mathbb{R})$ is a flow, then there exists an ergodic measure ν on Ω. In fact, one can first use a classical construction of Krylov and

Bogoliubov to determine an *invariant* measure ν on Ω; see, e.g., [55,113]. We will make use of this construction below. Second, one notes that the set of invariant measures forms a weak-$*$ compact, convex set of the vector space of all Borel regular signed measures on Ω. By the Krein–Mil'man Theorem this set admits an extreme point. It is easy to see that such an extreme point is ergodic.

If Ω is a compact metric space and ν is a Borel regular measure on Ω, then the *topological support* $\operatorname{Supp}\nu$ of ν is by definition the complement in Ω of the largest open set $U \subset \Omega$ which has zero ν-measure. This concept is well defined and $\operatorname{Supp}\nu$ is compact. If ν is $\{\tau_t\}$-invariant, then $\operatorname{Supp}\nu$ is invariant. Observe that if $U \subset \operatorname{Supp}\nu$ is relatively open then $\nu(U) > 0$. If $(\Omega, \mathbb{R})$ is minimal then $\operatorname{Supp}\nu = \Omega$ for every invariant measure ν on Ω.

It may happen that a flow $(\Omega, \mathbb{R})$ admits a unique invariant measure ν. This is the case, for example, if $(\Omega, \mathbb{R})$ is minimal and almost periodic; in fact, the normalized Haar measure ν on Ω is the unique invariant measure. If $(\Omega, \mathbb{R})$ admits a unique invariant measure ν, then ν is ergodic. If $(\Omega, \mathbb{R})$ is minimal and admits a unique invariant (ergodic) measure ν, then $(\Omega, \mathbb{R})$ is said to be *strictly ergodic*.

We state a version of the Birkhoff Ergodic Theorem which is adequate for our purposes. For a formulation and proof of the general Birkhoff theorem see [113]. We include a refinement of the usual Birkhoff theorem in point (ii) of Theorem 2.1; for a proof of this statement see, e.g., [55].

THEOREM 2.1. *Let Ω be a compact metric space with flow $\{\tau_t\}$, and let ν be an ergodic measure on Ω.*

(i) *Let $f \in L^1(\Omega, \nu)$, then for ν-a.a. $\omega \in \Omega$ the time averages $\lim_{t\to\infty} \frac{1}{t}\int_0^t f(\omega\cdot s)\,\mathrm{d}s$ and $\lim_{t\to-\infty} \frac{1}{t}\int_0^t f(\omega\cdot s)\,\mathrm{d}s$ exist and equal $\int_\Omega f\,\mathrm{d}\nu$.*

(ii) *If Ω admits a unique ergodic measure ν and if f is continuous, then*

$$\lim_{|t|\to\infty} \frac{1}{t}\int_0^t f(\omega\cdot s)\,\mathrm{d}s = \int_\Omega f\,\mathrm{d}\nu$$

for all $\omega \in \Omega$, and the limit is uniform in Ω.

Next we state some facts concerning linear nonautonomous differential systems. We adopt the following point of view. Let Ω be a compact metric space, and let $(\Omega, \mathbb{R})$ be a flow. Let $A : \Omega \to \mathbb{M}_n$ be a continuous function. Consider the family of differential systems

$$x' = A(\omega\cdot t)x, \quad x \in \mathbb{R}^n,\ \omega \in \Omega. \tag{2.1$_\omega$}$$

We have already seen that, via the Bebutov construction, a linear differential equation $x' = A(t)x$ with uniformly continuous coefficient matrix $A(\cdot)$ gives rise to a family of this type. We will study the solutions of Eqs. (2.1$_\omega$) using the methods of topological dynamics and ergodic theory.

Let $\omega \in \Omega$, and let $\Phi_\omega(t)$ be the fundamental matrix solution of (2.1$_\omega$). The collection $\{\Phi_\omega(t) \mid \omega \in \Omega\}$ defines a map $\Phi : \Omega \times \mathbb{R} \to \mathrm{GL}(n, \mathbb{R}) : (\omega, t) \mapsto \Phi_\omega(t)$. We noted in Section 1 that Φ is a cocycle and that the maps $\tilde{\tau}_t : \Omega \times \mathbb{R}^n \to \Omega \times \mathbb{R}^n : \tilde{\tau}_t(\omega, x) = (\tau_t(\omega), \Phi_\omega(t)x)$ define a flow on $\Omega \times \mathbb{R}^n (t \in \mathbb{R})$.

Let $\mathbb{P}^{n-1}$ be the $(n-1)$ dimensional space of lines through the origin in $\mathbb{R}^n$. For each $t \in \mathbb{R}$, define $\hat{\tau} : \Omega \times \mathbb{P}^{n-1} \to \Omega \times \mathbb{P}^{n-1}$: $\hat{\tau}_t(\omega, l) = (\tau_t(\omega), \Phi_\omega(t)l)$. Here $l \in \mathbb{P}^{n-1}$ is acted on in the natural way by $\Phi_\omega(t) \in GL(n, \mathbb{R})$. Using the cocycle identity again, one can show that $(\Omega \times \mathbb{P}^{n-1}, \{\hat{\tau}_t\})$ is a flow. This is the *projective flow* defined by Eqs. (2.1_ω). If one wishes to study the "angular behavior" of the solutions of Eqs. (2.1_ω), the projective flow is one natural object to study. We will write

$$\Sigma = \Omega \times \mathbb{P}^{n-1}, \quad \pi : \Sigma \to \Omega : (\omega, l) \mapsto \omega$$

for $\omega \in \Omega, l \in \mathbb{P}^{n-1}$. The projection π is a flow homomorphism.

Let us now briefly discuss some key concepts concerning the family (2.1_ω). These concepts will later be specialized to the case of interest in this paper, namely that when $n = 2$.

Fix $\omega \in \Omega$. A number $\beta \in \mathbb{R}$ is called a *Lyapunov exponent* of Eq. (2.1_ω) if there is a nonzero vector $x_0 \in \mathbb{R}^n$ such that

$$\overline{\lim_{t\to\infty}} \frac{1}{t} \ln\left|\Phi_\omega(t)x_0\right| = \beta.$$

It is well-known that each fixed Eq. (2.1_ω) admits finitely many Lyapunov exponents $\beta_1 < \cdots < \beta_k$ where $1 \leqslant k \leqslant n$. Moreover, there is a filtration of $\mathbb{R}^n$ consisting of subspaces $\{0\} = V_0 \subset V_1 \subset \cdots \subset V_k = \mathbb{R}^n$ such that

$$V_r = \{0\} \cup \left\{0 \neq x_0 \in \mathbb{R}^n \;\middle|\; \overline{\lim_{t\to\infty}} \frac{1}{t} \ln\left|\Phi_\omega(t)x_0\right| \leqslant \beta_r\right\} \quad (1 \leqslant r \leqslant k).$$

See, e.g., [8]. Difficulties are caused by the fact that neither the Lyapunov exponents nor the filtration need to be continuous with respect to variation of ω.

The Oseledets theory furnishes information concerning this point and others. We do not give the most general version of the Oseledets theorem; the one we do give is, however, more than sufficient for our purposes. Let ν be an ergodic measure on Ω.

THEOREM 2.2 (Oseledets). *One can find a ν-measurable, invariant subset $\Omega_* \subset \Omega$ with $\nu(\Omega_*) = 1$, and real numbers $\beta_1 < \cdots < \beta_k$ with $1 \leqslant k \leqslant n$, with the following properties.*

(i) *If $\omega \in \Omega_*$ then for each $r = 1, 2, \ldots, k$ there is a nonzero vector $x_0 \in \mathbb{R}^n$ such that the limits $\lim_{t\to\infty} \frac{1}{t} \ln|\Phi_\omega(t)x_0|$ and $\lim_{t\to-\infty} \frac{1}{t} \ln|\Phi_\omega(t)x_0|$ both exist and equal β_r.*

(ii) *For each $\omega \in \Omega_*$ and each $r = 1, 2, \ldots, k$, the set*

$$W_r(\omega) = \{0\} \cup \left\{0 \neq x_0 \in \mathbb{R}^n \;\middle|\; \lim_{|t|\to\infty} \frac{1}{t} \ln\left|\Phi_\omega(t)x_0\right| = \beta_r\right\}$$

is a vector subspace of $\mathbb{R}^n$, of dimension $d_r \in \{1, 2, \ldots, n\}$. One has $d_1 + \cdots + d_k = n$. The mapping $\omega \mapsto W_r(\omega)$ is measurable as a function from Ω_* to the Grassmann manifold $\mathrm{Gr}(n, d_r)$ of d_r-dimensional subspaces of $\mathbb{R}^n$.

(iii) *For each* $r = 1, 2, \dots, k$, *the "measurable subbundle"*

$$W_r = \bigcup \bigl\{(\omega, x_0) \mid x_0 \in W_r(\omega), \omega \in \Omega_*\bigr\}$$

is invariant in the sense that $\Phi_\omega(t) W_r(\omega) = W_r(\omega \cdot t)$ *for all* $\omega \in \Omega_*$, $t \in \mathbb{R}$.

(iv) *For each* $\omega \in \Omega_*$, *there holds* $\beta_1 + \cdots + \beta_k = \lim_{|t|\to\infty} \frac{1}{t} \ln \det \Phi_\omega(t)$.

Point (i) defines the "Oseledets spectrum" of the family (2.1_ω). Point (iv) states that ν-a.a. systems (2.1_ω) are both forward and backward Lyapunov regular. For proofs of the Oseledets theorem see [129,8,94]. When $n = 2$ it is possible to give a quite simple proof of a strengthened version of the Oseledets Theorem. We will discuss this point later on.

Next we introduce the concept of *exponential dichotomy* [29,137]. Again let Ω be a compact metric space, and let $(\Omega, \mathbb{R})$ be a real flow. Let $A : \Omega \to \mathbb{M}_n$ be a continuous map, and consider the corresponding family of Eqs. (2.1_ω).

DEFINITIONS 2.3.

(a) The family $\{(2.1_\omega) \mid \omega \in \Omega\}$ is said to have an exponential dichotomy (ED) over Ω if there are positive constants η, δ together with a continuous, projection-valued function $P : \Omega \to \mathbb{M}_n$ (thus $P(\omega)^2 = P(\omega)$ for all $\omega \in \Omega$) such that the following estimates hold:
  (i) $|\Phi_\omega(t) P(\omega) \Phi_\omega(s)^{-1}| \leqslant \eta e^{-\delta(t-s)}$, $t \geqslant s$,
  (ii) $|\Phi_\omega(t)(I - P(\omega)) \Phi_\omega(s)^{-1}| \leqslant \eta e^{\delta(t-s)}$, $t \leqslant s$.

(b) The *dynamical* or *Sacker–Sell spectrum* of the family (2.1_ω) is $\{\lambda \in \mathbb{R} \mid$ the translated equations $x' = [-\lambda I + A(\omega \cdot t)]x$ do *not* admit an exponential dichotomy over $\Omega\}$.

If Eqs. (2.1_ω) admit an exponential dichotomy over Ω, then it is easy to see that $\Omega \times \mathbb{R}^n$ splits into a Whitney sum of the vector subbundles $W_1 = \{(\omega, x) \in \Omega \times \mathbb{R}^n \mid x \in \operatorname{Im} P(\omega)\}$ and $W_2 = \{(\omega, x) \in \Omega \times \mathbb{R}^n \mid x \in \operatorname{Ker} P(\omega)\}$. Of course it can happen that $P(\omega) = 0$ or $P(\omega) = I$. If Ω is connected then the dimension of $\operatorname{Im} P(\omega)$ does not depend on Ω.

The following theorem is due to Sacker and Sell [137,138]; see also Selgrade [142].

THEOREM 2.4. *Let* Ω *be a compact connected metric space, and let* $(\Omega, \mathbb{R})$ *be a flow. Let* $A : \Omega \to \mathbb{M}_n$ *be a continuous map.*

(a) *The dynamical spectrum of the family* (2.1_ω) *is a finite union* $[a_1, b_1] \cup \cdots \cup [a_k, b_k]$ *of compact subintervals of* $\mathbb{R}$, *where* $1 \leqslant k \leqslant n$. *Some or all of these intervals may degenerate to points.*

(b) *For each* $r = 1, 2, \dots, k$ *set*

$$W_r = \left\{ (\omega, x) \in \Omega \times \mathbb{R}^n \;\middle|\; x_0 = 0 \text{ or } \Bigl(\limsup_{t\to\infty}, \liminf_{t\to\infty}\Bigr) \frac{1}{t} \ln\bigl|\Phi_\omega(t) x_0\bigr| \in [a_r, b_r] \right.$$
$$\left. \text{and } \Bigl(\limsup_{t\to-\infty}, \liminf_{t\to-\infty}\Bigr) \frac{1}{t} \ln\bigl|\Phi_\omega(t) x_0\bigr| \in [a_r, b_r] \right\}.$$

Then W_r is a topological vector subbundle of $\Omega \times \mathbb{R}^n$. One has

$$\Omega \times \mathbb{R}^n = W_1 \oplus W_2 \oplus \cdots \oplus W_k \quad (\textit{Whitney sum}).$$

There are various relations between the "Oseledets bundles" and the "Sacker–Sell bundles", and between the Oseledets spectrum and the dynamical spectrum. See [94] for a discussion of this issue.

Let us now consider the case $n = 2$. As we will see, there is no loss of generality for present purposes in assuming that the trace $\operatorname{tr} A(\omega) = 0$ for all $\omega \in \Omega$. Thus we assume that

$$A : \Omega \to \mathrm{sl}(2, \mathbb{R})$$

is a continuous function. Let us introduce the basis $\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$, $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ of $\mathrm{sl}(2, \mathbb{R})$. We expand $A(\cdot)$ with respect to this basis:

$$A = \begin{pmatrix} a & -b + c \\ b + c & -a \end{pmatrix}$$

where $a, b, c : \Omega \to \mathbb{R}$ are continuous functions.

Consider the family of equations

$$x' = A(\omega \cdot t)x, \quad x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \ \omega \in \Omega. \tag{2.2$_\omega$}$$

Let us express these equations in polar coordinates $r^2 = x_1^2 + x_2^2$, $\theta = \arctan \frac{x_2}{x_1}$:

$$\frac{r'}{r} = a(\omega \cdot t) \cos 2\theta + c(\omega \cdot t) \sin 2\theta,$$

$$\theta' = b(\omega \cdot t) - a(\omega \cdot t) \sin 2\theta + c(\omega \cdot t) \cos 2\theta.$$

If we think of θ as a π-periodic angular variable on the real projective space $\mathbb{P}$, then the θ-equation gives a concrete way of studying the projective flow defined by Eqs. (2.1$_\omega$). In fact, let $l_0 \in \mathbb{P}$, $\omega_0 \in \Omega$, and suppose that l_0 is parameterized by $\theta_0 \in \mathbb{R}$. Let $\theta(t)$ satisfy the θ-equation with $\theta(0) = \theta_0$ and $\omega = \omega_0$. Then $\hat{\tau}_t(\omega_0, l_0) = \hat{\tau}_t(\omega_0, \theta_0) = (\tau_t(\omega), \theta(t))$. It is understood that $\theta(t)$ is identified with the line through the origin in $\mathbb{R}^2$ which it parametrizes.

Next let us write

$$f : \Sigma \to \mathbb{R}\colon\ f(\omega, \theta) = a(\omega) \cos 2\theta + c(\omega) \sin 2\theta,$$

$$g : \Sigma \to \mathbb{R}\colon\ g(\omega, \theta) = b(\omega) - a(\omega) \sin 2\theta + c(\omega) \cos 2\theta.$$

Then Eqs. (2.2$_\omega$) are expressed in polar coordinates r, θ as follows:

$$\frac{r'}{r} = f\bigl(\hat{\tau}_t(\omega, \theta)\bigr), \tag{2.3$_\omega$}$$

$$\theta' = g\big(\hat{\tau}_t(\omega, \theta)\big). \tag{2.4_ω}$$

Let $0 \neq x_0 \in \mathbb{R}^2$ have polar angle θ_0, and let $\theta(t)$ be the solution of (2.4_ω) satisfying $\theta(0) = \theta_0$. Let $r(t) = |x(t)|$, where $x(t)$ satisfies (2.2_ω) with $x(0) = x_0$. Then

$$\frac{1}{t} \ln r(t) = \frac{1}{t} \ln r(0) + \frac{1}{t} \int_0^t f\big(\hat{\tau}_s(\omega, \theta_0)\big)\, \mathrm{d}s. \tag{2.5}$$

Thus there is a close connection between the Lyapunov exponents of Eq. (2.2_ω) and the time averages of f. Using the Birkhoff Theorem, we can thus relate the Lyapunov exponents of Eq. (2.2_ω) to the averages of f with respect to the $\{\tau_t\}$-ergodic measures μ on Σ.

Following [78], we indicate how an analysis of the ergodic averages of f permits one to prove the Oseledets Theorem 2.2 and the Sacker–Sell Theorem 2.4 in the case $n = 2$. We sketch the necessary arguments in the case when $(\Omega, \mathbb{R})$ admits a unique invariant measure ν (which is then ergodic). As mentioned earlier, this condition is valid if Ω is minimal and almost periodic. As we go along, we will illustrate the Krylov–Bogoliubov construction, together with some simple but useful techniques.

Note first that there exists an ergodic measure μ on Σ. The image of μ under the projection $\pi : \Sigma \to \Omega$ is an invariant measure, hence equals ν. We distinguish two possibilities:

(a) $\int_\Sigma f\, \mathrm{d}\mu = 0$,

(b) $\int_\Sigma f\, \mathrm{d}\mu \neq 0$.

Here f is the function occurring in (2.3_ω).

Suppose that (a) holds. We will prove that all Lyapunov exponents of all Eqs. (2.2_ω) are zero.

PROPOSITION 2.5. *Suppose that there is an ergodic measure μ on Σ such that $\int_\Sigma f\, \mathrm{d}\mu = 0$. Let $\varepsilon > 0$ be given. Then there exists $T > 0$ such that, if $\omega \in \Omega$ and if $x_0 \in \mathbb{R}^2$ satisfies $|x_0| = 1$, then*

$$-\varepsilon \leqslant \frac{1}{t} \ln\big|\Phi_\omega(t) x_0\big| \leqslant \varepsilon \quad \textit{whenever } |t| > T.$$

PROOF. We make systematic use of Eq. (2.5), which relates the asymptotic behavior of the quantities $\frac{1}{t} \ln |\Phi_\omega(t) x_0|$ to the time averages of f. Suppose for contradiction that there are sequences $(\omega_k) \subset \Omega$, $(x_k) \subset \mathbb{R}^2$, and $(t_k) \subset \mathbb{R}$ such that $|x_k| = 1$, $|t_k| \to \infty$, and

$$\left| \frac{1}{t_k} \int_0^{t_k} f\big(\hat{\tau}_s(\omega_k, l_k)\big)\, \mathrm{d}s \right| \geqslant \varepsilon.$$

Here $l_k \in \mathbb{P}$ is the line through the origin in $\mathbb{R}^2$ containing x_k. Passing to subsequences if necessary, we can assume that $\lim_{k\to\infty} \frac{1}{t_k} \int_0^{t_k} f(\hat{\tau}_s(\omega_k, l_k))\, \mathrm{d}s$ exists. Call the limit $\Lambda(f)$. Clearly $\Lambda(f) \neq 0$.

Let $C(\Sigma) = \{h : \Sigma \to \mathbb{R} \mid h \text{is continuous}\}$. Let $\mathcal{H}$ be a countable dense $\mathbb{Q}$-vector subspace of $C(\Sigma)$. Using a Cantor diagonal argument, one can determine a subsequence (t_m) of (t_k) such that for each $h \in \mathcal{H}$ the limit

$$\lim_{m\to\infty} \frac{1}{t_m} \int_0^{t_m} h\bigl(\hat{\tau}_s(\omega_m, l_m)\bigr)\, \mathrm{d}s$$

exists. Call the limit $\Lambda(h)$ ($h \in \mathcal{H}$). It is easy to see that Λ defines a $\mathbb{Q}$-linear, bounded functional on $\mathcal{H}$, and that $|\Lambda| = 1$. This functional extends uniquely to a $\mathbb{R}$-linear functional – which we also call Λ – on $C(\Sigma)$. One sees that $|\Lambda| \leqslant 1$, and in fact $|\Lambda| = 1$ because, if we let h be the function on Σ whose only value is 1, then $\Lambda(h) = 1$. Moreover, Λ is invariant in the sense that, if $h \in C(\Sigma)$, $t \in \mathbb{R}$, and $(\hat{\tau}_t h)(\sigma) =: h(\hat{\tau}_{-t}(\sigma))$ for each $\sigma \in \Sigma$, then

$$\Lambda(\hat{\tau}_t h) = \Lambda(h).$$

By the Riesz representation theorem, there is a unique Borel regular probability measure μ_Λ on Σ such that $\Lambda(h) = \int_\Sigma h\, \mathrm{d}\mu_\Lambda$ for all $h \in C(\Sigma)$. One checks that μ_Λ is invariant. Clearly $\int_\Sigma f\, \mathrm{d}\mu_\Lambda \neq 0$.

Now let I be the weak-$*$ compact, convex subset of the dual space $C^*(\Sigma)$ which consists of the set of $\{\hat{\tau}_t\}$-invariant measures on Σ (or rather, the linear functionals which correspond to them under the Riesz theorem). Applying the Choquet theory [131] to the set I, and taking account of the fact that ergodic measures on Σ correspond to extreme points of I, one sees that there exists an ergodic measure μ_1 on Σ such that $\int_\Sigma f\, \mathrm{d}\mu_1 \neq 0$. Write $\beta = \int_\Sigma f\, \mathrm{d}\mu_1$.

Next, use the Birkhoff ergodic theorem to find a μ_1-measurable, invariant set $\Sigma_1 \subset \Sigma$ with $\mu_1(\Sigma_1) = 1$, such that, if $\sigma \in \Sigma_1$, then

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t f\bigl(\hat{\tau}_s(\sigma)\bigr)\, \mathrm{d}s = \lim_{t\to-\infty} \frac{1}{t} \int_0^t f\bigl(\hat{\tau}_s(\sigma)\bigr)\, \mathrm{d}s = \beta.$$

Let $\Omega_1 = \pi(\Sigma_1)$; then Ω_1 is ν-measurable, invariant and $\nu(\Omega_1) = 1$. In a similar way, we can find a μ-measurable, invariant set $\Sigma_* \subset \Sigma$ with $\mu(\Sigma_*) = 1$, such that, if $\sigma \in \Sigma_*$, then

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t f\bigl(\hat{\tau}_s(\sigma)\bigr)\, \mathrm{d}s = \lim_{t\to-\infty} \frac{1}{t} \int_0^t f\bigl(\hat{\tau}_s(\sigma)\bigr)\, \mathrm{d}s = 0.$$

Let $\Omega_* = \pi(\Sigma_*)$; then Ω_* is also ν-measurable with $\nu(\Omega_*) = 1$.

Choose $\omega \in \Omega_1 \cap \Omega_*$, then pick points $(\omega, l_1) \in \Sigma_1$ and $(\omega, l_*) \in \Sigma_*$. Clearly $l_1 \neq l_*$. Let $x_1 \in l_1$ and $x_* \in l_*$ have norm 1; then x_1 and x_* are linearly independent. Let $x_1(t) = \Phi_\omega(t)x_1$, $x_*(t) = \Phi_\omega(t)x_*$. Let $\Psi(t)$ be the matrix solution of Eq. (2.2_ω) whose columns are $x_1(t)$ and $x_*(t)$. By Liouville's formula $\det\Psi(t) = \det\Psi(0) = const.$ for all $t \in \mathbb{R}$. However, using relation (2.5), we see that $\lim_{t\to\infty} \det\Psi(t) = 0$ if $\beta < 0$ and that $\lim_{t\to-\infty} \det\Psi(t) = 0$ if $\beta > 0$. This is a contradiction. The proof of Proposition 2.5 is complete. □

Proposition 2.5 states that, if there is an ergodic measure μ on Σ for which $\int_\Sigma f\,\mathrm{d}\mu = 0$, then $\lim_{|t|\to\infty} \frac{1}{t}\ln|\Phi_\omega(t)x| = 0$, uniformly in $\omega \in \Omega$ and $x \in \mathbb{R}^2$ with $|x| = 1$. Thus all Lyapunov exponents of all Eqs. (2.2_ω) are zero, and this holds in a uniform way. Now let us describe what happens in the case when there is an ergodic measure μ_1 on Σ for which $\int_\Sigma f\,\mathrm{d}\mu_1 = \beta \neq 0$, i.e., the case (b).

First of all, using the Birkhoff ergodic theorem, we can find a μ_1-measurable, invariant set $\Sigma_1 \subset \Sigma$ with $\mu_1(\Sigma_1) = 1$ such that $\lim_{|t|\to\infty} \frac{1}{t}\int_0^t f(\hat{\tau}_s(\sigma))\,\mathrm{d}s = \beta$ for all $\sigma \in \Sigma_1$. Let $\Omega_1 = \pi(\Sigma_1)$, so that Ω_1 is ν-measurable, invariant, and $\nu(\Omega_1) = 1$. We claim that, for each $\omega_1 \in \Omega_1$, the fiber $\pi^{-1}(\omega_1) \cap \Sigma_1$ contains exactly one point. For, suppose that $(\omega_1, l_1) \in \Sigma_1$ and $(\omega_1, l_*) \in \Sigma_1$, where $l \neq l_*$. Then, using Liouville's formula and relation (2.5) as was done in the last part of the proof of Proposition 2.5, we argue to a contradiction. We thus conclude that Σ_1 is a ν-measurable invariant section in Σ when Σ is viewed as a fiber bundle over Ω.

Further reasoning of this elementary sort can be used to prove the following facts; see [78]. First, there is exactly one other ergodic measure μ_2 on Σ. Second, $\int_\Sigma f\,\mathrm{d}\mu_2 = -\beta$. Third, there is a ν-measurable, invariant section $\Sigma_2 \subset \Sigma$ such that $\mu_2(\Sigma_2) = 1$. The measurable invariant sections define measurable subbundles $W_{1,2} \subset \Omega \times \mathbb{R}^2$ of fiber dimension one.

There are now just two possibilities.

(i) The invariant measurable sections Σ_1, Σ_2 extend to continuous invariant sections of Σ. In this case, W_1 and W_2 are clearly topological subbundles of $\Omega \times \mathbb{R}^2$ of fiber dimension one. One can show that $\Omega \times \mathbb{R}^2 = W_1 \oplus W_2$ (Whitney sum). It is now easily verified that the dynamical spectrum of the family (2.4_ω) coincides with the two point set $\{-\beta, \beta\}$. See [78] for details.

(ii) The invariant sections Σ_1, Σ_2 do not extend to continuous sections of Σ. In this case, one can show that the dynamical spectrum of the family (2.4_ω) coincides with the interval $[-\beta, \beta]$. On the other hand, the Oseledets spectrum is the two point set $\{-\beta, \beta\}$. The Oseledets bundles are (ν-a.e.) the bundles W_1 and W_2. See again [78] for details.

Examples of type (ii) are particularly interesting and invariably give rise to projective flows with interesting structure. As noted in the Introduction, Millionščikov [108] and Vinograd [152] constructed examples of families (2.4_ω) for which $(\Omega, \mathbb{R})$ is an almost periodic minimal set and for which the conditions in (ii) turned out to be true. They were motivated by the search for almost periodic linear differential systems which are not almost reducible, and which are therefore not regular in the sense of Lyapunov. In what follows, we will refer to the number β as the Lyapunov exponent of the family (2.1_ω). The above discussion shows that, if $\beta = 0$, then $\lim_{|t|\to\infty} \frac{1}{t}\ln|\Phi_\omega(t)x_0| = 0$, uniformly with respect to $\omega \in \Omega$ and $x_0 \in \mathbb{R}^2$ satisfying $|x_0| = 1$.

Let us finish this section by defining and briefly discussing the rotation number for Eqs. (2.2_ω). This quantity was defined, and certain of its properties were worked out, in [89]. See also [81] for a further discussion of properties of the rotation number and for a generalization of this concept. It is related to the so-called integrated density of states [147]. A discrete version of the rotation number – the fiber rotation number – was worked out in [68].

The rotation number is most easily defined and analyzed using Eqs. (2.4_ω) for the polar angle θ. Let Ω be a compact metric space, let $(\Omega, \mathbb{R})$ be a flow, and let ν be an ergodic measure on Ω. Consider the function g in (2.4_ω): if $\omega \in \Omega$, $\theta_0 \in \mathbb{R}$, and if $\theta(t)$ is the solution of Eq. (2.4_ω) with $\theta(0) = \theta_0$, then

$$\theta(t) = \theta_0 + \int_0^t g\big(\hat{\tau}_s(\omega_0)\big)\,\mathrm{d}s. \tag{2.6}$$

We state the

DEFINITION 2.6. The *rotation number* α_ν of Eqs. (2.2_ω) with respect to the ergodic measure ν on Σ is

$$\alpha_\nu = \lim_{t\to\infty} \frac{\theta(t)}{t}.$$

Of course one has to prove that this definition makes sense, i.e. that the limit exists in an appropriate sense. It turns out that there is a ν-measurable, invariant set $\Omega_\nu \subset \Omega$ with $\nu(\Omega_\nu) = 1$ such that, if $\omega \in \Omega_\nu$, $\theta_0 \in \mathbb{P} = \mathbb{R}/\pi\mathbb{Z}$ and $\theta(t)$ is the solution of (2.4_ω) with $\theta(0) = \theta_0$, then $\lim_{|t|\to\infty} \frac{\theta(t)}{t}$ exists and does not depend on the choice of $(\omega, \theta_0) \in \Omega_\nu \times \mathbb{P}$. In fact, for each ergodic measure μ on Σ which is a lift of ν in the sense that $\pi(\mu) = \nu$, one has

$$\lim_{|t|\to\infty} \frac{\theta(t)}{t} = \int_\Sigma g\,\mathrm{d}\mu. \tag{2.7}$$

In particular, the right-hand side of (2.7) does not depend on the choice of the ergodic lift μ of ν. The proofs of these statements use (2.6), the Birkhoff ergodic theorem, and certain special arguments. See [89] for details.

It turns out that α has good continuity properties. We discuss one which turns out to be significant. A proof of the following statement can be based on an argument of Krylov–Bogoliubov type; see [89] for arguments of the appropriate type. There are various other continuity results concerning the rotation number. Some of these will be stated later when they are needed.

PROPOSITION 2.7. *Let Ω be a compact metric space, let $(\Omega, \{\tau_t\})$ be a flow, and let ν_k be a sequence of measures which are ergodic with respect to $\{\tau_t\}$. Suppose that ν is a $\{\tau_t\}$-ergodic measure on Ω, and suppose that $\nu_k \to \nu$ in the weak-$*$ sense. Then $\alpha_{\nu_k} \to \alpha_\nu$.*

3. The projective flow

Let us first recall some basic facts concerning a linear periodic system

$$x' = A(t)x, \quad x \in \mathbb{R}^n \tag{3.1}$$

where $A(t) = A(t + 2\pi)$ is a continuous function with values in $\mathbb{M}_n$. Let $\Phi(t)$ be the fundamental matrix solution of (3.1). The asymptotic behavior of the solution of (3.1) is determined by the Floquet matrix $\Phi(2\pi)$ and its iterates. For example, knowledge of the real parts of the logarithms of the eigenvalues and of the generalized eigenspaces of $\Phi(2\pi)$ permit one to determine which solutions of (3.1) exhibit exponential growth or decay, and with which rates.

We wish to understand the directional variation of the solutions of (3.1). Though the concept of "directional variation" does not have immediate significance, it can be rendered meaningful using the imaginary parts of the logarithms of the eigenvalues of $\Phi(2\pi)$ together with its generalized eigenspaces. Alternatively, one can use the Floquet "theory" to determine an invertible, 4π-periodic matrix function $L = L(t)$ such that the change of variables $x = L(t)y$ transforms (3.1) into

$$y' = Ry$$

for a constant real matrix R. Using the generalized eigenspaces and the imaginary parts of the eigenvalues of R, one can develop a theory concerning the rates with which solutions of (3.1) change direction with time, and related matters.

Suppose now that $A(\cdot)$ is nonperiodic. We seek information concerning the asymptotic behavior of the solutions of (3.1). We have seen in Section 2 that the concepts of Lyapunov exponent and exponential dichotomy allow one to develop profound theories concerning the exponential growth of the solutions of (3.1). However it is not clear how one might develop a reasonable theory of the directional variation of those solutions. In this regard, one might for example ask for an analogue of the Floquet theory in the context of nonperiodic systems (3.1). However, it is well known that one cannot hope in general to reduce (3.1) to a system with constant coefficients by mean of a bounded and boundedly invertible change of variables $x = L(t)y$. The search for an analogue of the period matrix $\Phi(2\pi)$ is even more problematic. In fact, it seems difficult to elaborate this concept in a useful way even in the case when $A(\cdot)$ is almost periodic and there exist "almost periods" with a definite meaning.

We therefore try to formulate a theory of the directional variation of the solutions of (3.1) in the nonperiodic case from another point of view. Suppose that a Bebutov-type construction has been carried out, with the following results: a compact metric space Ω, a flow $\{\tau_t\}$ on Ω, a continuous function $A : \Omega \to \mathbb{M}_n$, and a family of equations

$$x' = A\big(\tau_t(\omega)\big)x \tag{3.1_ω}$$

which contains (3.1). Let $\mathbb{P}$ be the $(n-1)$-dimensional projective space of lines through the origin in $\mathbb{R}^n$. Let $\Sigma = \Omega \times \mathbb{P}$. We define a flow $\{\hat{\tau}_t\}$ on Σ as was done in Section 2. Namely, let $\Phi_\omega(t)$ be the fundamental matrix solution of (3.1_ω). Let $\omega \in \Omega$, $l \in \mathbb{P}$ and set

$$\hat{\tau}_t(\omega, l) = \big(\tau_t(\omega), \Phi_\omega(t)l\big)$$

where $\Phi_\omega(t)$ acts linearly on l for each $t \in \mathbb{R}$.

We propose to study the directional variation of the solutions of Eqs. (3.1_ω) by collecting information about the compact invariant subsets of Σ. In particular, we would like to classify the minimal subsets of $(\Sigma, \mathbb{R})$.

When $n \geqslant 3$, the study of the projective flow $(\Sigma, \mathbb{R})$ is still in its infancy, though there is a substantial body of particular results. We remark that there is no reason to restrict attention to the projective flow. It is of interest to substitute $\mathbb{P}$ with other compact homogeneous spaces H of the general linear group or of a Lie subgroup thereof, and study the flow on $\Omega \times H$ induced by Eqs. (3.1_ω). See [46–49,81,90–93,120].

Let us now consider the case when $n = 2$. Then $\mathbb{P}$ is the projective circle, and Σ is a trivial circle bundle over Ω with projection $\pi : \Sigma \to \Omega$: $(\omega, l) \mapsto \omega$. Even in this relatively simple case, we will find diverse phenomena which illustrate the complexity of the directional variation of the solutions of linear differential systems with nonperiodic coefficients.

It is easy to classify the possible projective flows $(\Sigma, \mathbb{R})$ when $n = 2$ and when Ω is the Bebutov hull of a periodic function $A(\cdot)$. This classification can serve as a guide to the study of $(\Sigma, \mathbb{R})$ in more general cases. So return to Eq. (3.1) for a moment, and assume that $A(t + 2\pi) = A(t)$ for all $t \in \mathbb{R}$. We view A as an element of $\mathcal{C} = \{C : \mathbb{R} \to \mathbb{M}_2 \mid C \text{ is continuous and bounded}\}$ with the compact-open topology. We carry out the Bebutov construction beginning with A and obtain a compact hull Ω which is homeomorphic to a circle. In fact, we can think of $\omega \in \Omega$ as an angular coordinate on this circle, so that a generic element of Ω has the form A_ω where $A_\omega(\cdot) = A(\omega + \cdot)$. The space $\Sigma = \Omega \times \mathbb{P}$ is a two-torus.

Let us consider the following model equations:

(α) $x' = \begin{pmatrix} a & 0 \\ 0 & -a \end{pmatrix} x$, $a > 0$;

(β) $x' = \begin{pmatrix} 0 & -b \\ b & 0 \end{pmatrix} x$, $b \in \mathbb{R}$;

(γ) $x' = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} x$

where $x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2$. We view the coefficients matrices as constant functions defined on Ω. Let us examine the corresponding projective flows.

Case (α) There are exactly two minimal subsets $M_1, M_2 \subset \Sigma$; these are flow isomorphic to Ω via the projection $\pi : \Sigma \to \Omega$. In fact, if $l_1 \subset \mathbb{R}^2$ denotes the x_1-axis and $l_2 \subset \mathbb{R}^2$ denotes the x_2-axis, then $M_i = \{(\omega, l_i) \mid \omega \in \Omega\}$, $i = 1, 2$. The orbits in Σ which lie off $M_1 \cup M_2$ exhibit an hyperbolic structure.

Case (β) If $\frac{b}{2\pi}$ is rational, then the flow on Σ laminates in an obvious sense into uncountably many minimal subsets. If $b = 0$ these are defined by conditions of the type $l = constant$. If $\frac{b}{2\pi} = \frac{p}{q}$ where $q \geqslant 1$ and the fraction is expressed in lowest terms, then each minimal set defines a closed curve in Σ which winds q times around Ω as one traverses the circle $\mathbb{P}$. On the other hand, if $\frac{b}{2\pi}$ is irrational, then Σ itself is a minimal set, and the flow on Σ is a Kronecker winding. The orbits in Σ exhibit an elliptic structure.

Case (γ) Let $l_1 \in \mathbb{R}^2$ be the x_1-axis, and let $M = \{(\omega, l_1) \mid \omega \in \Omega\}$. Then $M \subset \Sigma$ is the unique minimal subset of Σ. The orbits of Σ which lie off M exhibit a parabolic structure.

It is rather easy to show that, when $A(\cdot)$ is 2π-periodic, then there is a flow isomorphism between the projective flow defined by Eqs. (3.1_ω) and one of the flows considered in the cases (α), (β) and (γ). To see this, note first that the projective flow $(\Sigma, \mathbb{R})$ does not change if a 2π-periodic, continuous function of the form $\delta(t)\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ is added to $A(t)$, so choosing $\delta(t) = -\frac{1}{2} \operatorname{tr} A(t)$, we can arrange that the trace $\operatorname{tr} A(t)$ is zero of all $t \in \mathbb{R}$.

Assuming this, the Floquet theory assures the existence of a 4π-periodic change of variables $x = L(t)y$ which brings (3.1) to the form

$$y' = Ry$$

where R has one of the forms (α), (β), (γ) (this uses the fact that $L(\cdot)$ can be chosen to have values in $\mathrm{SL}(2,\mathbb{R})$). Now, the projective flow is insensitive to the 2π – respectively 4π – periodicity of the function L. We take advantage of this fact as follows: viewing ω as an angular coordinate on the circle Ω, we define $h : \Sigma \to \Sigma$: $h(\omega, l) = (\omega, L(\omega)l)$. One can check that h defines a flow isomorphism between the flow $(\Sigma, \mathbb{R})$ defined by the appropriate model equation, and the $(\Sigma, \mathbb{R})$ defined by the family (3.1_ω).

Let us now turn to a discussion of the projective flow in the nonperiodic case. For the rest of Section 3, we will assume that $(\Sigma, \mathbb{R})$ is a minimal flow. Frequently we will assume in addition that it is Bohr almost periodic. Let $A : \Omega \to \mathbb{M}_2$ be a continuous function. The family of Eqs. (3.1_ω):

$$x' = A(\omega \cdot t)x$$

defines a flow $(\Sigma, \mathbb{R})$.

One might ask for a classification up to flow isomorphism of all possible projective flows, for all such continuous maps A. This seems to be a completely hopeless endeavor. We set a more modest goal, and ask for a description of the possible minimal subsets of Σ. Progress along these lines has been made. We will describe this progress, and will encounter along the way a rich collection of interesting minimal sets which supplies examples illustrating various phenomena which often are not related in an a priori way to properties of two-dimensional linear differential systems.

Before beginning, let us observe that the projective flow $(\Sigma, \mathbb{R})$ is unchanged if the diagonal matrix function $-\frac{1}{2}\operatorname{tr} A(\cdot)\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$ is added to $A(\cdot)$. Hence for present purposes, there is no loss of generality in assuming that the trace $\operatorname{tr} A(\cdot) = 0$, that is, that A takes values is the Lie algebra $\mathrm{sl}(2,\mathbb{R})$. For the rest of Section 3, we will assume that A is a continuous, $\mathrm{sl}(2,\mathbb{R})$-valued function on Ω.

We begin the discussion with a lemma which will be applied several times in what follows. We give a proof which uses some basic techniques in the theory of nonautonomous differential systems.

LEMMA 3.1. *Let $(\Omega, \mathbb{R})$ be a minimal flow, and let $f : \Omega \to \mathbb{R}$ be a continuous function. Suppose that there is an invariant measure ν_0 on Ω such that $\int_\Omega f\,\mathrm{d}\nu_0 = 0$. Then one of the following conditions holds.*

(i) *There is a continuous function $F : \Omega \to \mathbb{R}$ such that $F(\omega \cdot t) - F(\omega) = \int_0^t f(\omega \cdot s)\,\mathrm{d}s$ $(\omega \in \Omega, t \in \mathbb{R})$.*

(ii) *There is a residual subset $\Omega_* \subset \Omega$ such that, if $\omega_* \in \Omega_*$, then*

$$\limsup_{t\to\infty} \int_0^t f(\omega_* \cdot s)\,\mathrm{d}s = \infty, \qquad \liminf_{t\to\infty} \int_0^t f(\omega_* \cdot s)\,\mathrm{d}s = -\infty,$$

$$\limsup_{t\to-\infty}\int_0^t f(\omega_*\cdot s)\,\mathrm{d}s=\infty,\qquad \liminf_{t\to-\infty}\int_0^t f(\omega_*\cdot s)\,\mathrm{d}s=-\infty.$$

Condition (i) *holds if and only if there is a point* $\omega_0\in\Omega$ *such that* $\int_0^t f(\omega_0\cdot s)\,\mathrm{d}s$ *is bounded. Furthermore, if* (i) *holds, then* $\int_\Omega f\,d\nu=0$ *for every invariant measure* ν *on* Ω.

PROOF. We define a flow $\{\tilde\tau_t\mid t\in\mathbb{R}\}$ on $\Omega\times\mathbb{R}$ as follows: $\tilde\tau_t(\omega,x)=(\tau_t(\omega),x+\int_0^t f(\omega\cdot s)\,\mathrm{d}s)$; it is easy to check that $\{\tilde\tau_t\}$ is indeed a flow. Let $\tilde\pi:\Omega\times\mathbb{R}\to\Omega$ be the projection; it is a flow homomorphism.

Let us now first assume that there is a point $\omega_0\in\Omega$ such that $\int_0^t f(\omega_0\cdot s)\,\mathrm{d}s$ is bounded. The orbit $\{\tilde\tau_t(\omega_0,0)\mid t\in\mathbb{R}\}\subset\Omega\times\mathbb{R}$ is bounded, hence its closure D is compact and $\{\tilde\tau_t\}$-invariant. Let $M\subset D$ be a minimal subset. We claim that M defines a section of $\Omega\times\mathbb{R}$; that is, there exists a continuous function $\varphi:\Omega\to\mathbb{R}$ such that $M=\{(\omega,\varphi(\omega))\mid \omega\in\Omega\}$.

To see this, suppose that there exist a point $\omega\in\Omega$ and points $x_1,x_2\in\mathbb{R}$ such that $(\omega,x_i)\in M$ $(i=1,2)$. Let $\delta=|x_2-x_1|$, and let $T_\delta:\Omega\times\mathbb{R}\to\Omega\times\mathbb{R}$ be the map $T_\delta(\omega,x)=(\omega,x+\delta)$. Then $T_\delta(M)=M$ by invariance and minimality of M. Suppose that $\delta\neq0$. Then $T_{n\delta}(M)=M$ $(n=0,\pm1,\pm2,\ldots)$. But then M is not compact. This contradiction proves that $\delta=0$. It follows that there is a function $\varphi:\Omega\to\mathbb{R}$ such that $M=\{(\omega,\varphi(\omega))\mid\omega\in\Omega\}$. The continuity of φ follows from the compactness of M.

Let us now define $F(\omega)=\varphi(\omega)$ $(\omega\in\Omega)$. Then for each $\omega\in\Omega$ and $t\in\mathbb{R}$, we have $F(\omega\cdot t)-F(\omega)=\int_0^t f(\omega\cdot s)\,\mathrm{d}s$. That is, F satisfies the condition (i).

It is clear that, if (i) holds, then $\int_0^t f(\omega\cdot s)\,\mathrm{d}s$ is bounded for every $\omega\in\Omega$. So we have verified the equivalence of (i) with the boundedness of the integrals $\int_0^t f(\omega\cdot s)\,\mathrm{d}s$.

Next, suppose that condition (i) does not hold. We will prove that the oscillation conditions (ii) are valid. To do so, we will adapt to the present (simple) situation techniques which are used by Sacker and Sell to prove a basic result in the theory of exponential dichotomies ([137]; see also Selgrade [142] and Mañé [105]).

To facilitate comparison with [137], we introduce the family of one-dimensional linear systems

$$x'=f(\omega\cdot t)x,\quad x\in\mathbb{R}\tag{3.2$_\omega$}$$

Let $\varphi(\omega,t)=\exp\int_0^t f(\omega\cdot s)\,\mathrm{d}s$ be the solution of (3.2$_\omega$) satisfying $\varphi(\omega,0)=1$. Equations (3.2$_\omega$) define a flow $\{\tilde\tau_t\mid t\in\mathbb{R}\}$ on $\Omega\times\mathbb{R}$, as follows: $\tilde\tau_t(\omega,x)=(\tau_t(\omega),\varphi(\omega,t)x)$. Here $\{\tilde\tau_t\}$ has a different meaning as compared to the preceding lines.

Let us assume that there is a constant c such that $\int_0^t f(\omega\cdot s)\,\mathrm{d}s\leqslant c$ for all $\omega\in\Omega$ and $t\geqslant0$; we will presently see that this assumption leads to a contradiction. One checks that if our assumption holds, then $\int_0^t f(\omega\cdot s)\,\mathrm{d}s\geqslant -c$ for all $\omega\in\Omega, t\leqslant0$. Since condition (i) does not hold, we have that $\int_0^t f(\omega\cdot s)\,\mathrm{d}s$ is unbounded above as $t\to-\infty$, for each $\omega\in\Omega$. This means that, for each $\omega\in\Omega$, the only solution $x(t)$ of (3.2$_\omega$) which is bounded on all of $\mathbb{R}$ is the zero solution $x(t)\equiv0$.

We continue to assume that $\int_0^t f(\omega\cdot s)\,\mathrm{d}s\leqslant c$ for all $\omega\in\Omega, t\geqslant0$. We claim that $\varphi(\omega,t)$ decays to zero in a uniform exponential manner as $t\to\infty$. To see this, we first show that, for each $\omega \in \Omega$, $\varphi(\omega, t) \to 0$ as $t \to \infty$. For, if were not the case, there would exist $\delta > 0$, $\omega \in \Omega$, and a sequence $t_k \to \infty$ such that $\varphi(\omega, t_k) \geqslant \delta$ $(k = 1, 2, \ldots)$. Passing to a subsequence if necessary, we can assume that $\tau_{t_k}(\omega) \to \bar{\omega}$ and $\varphi(\omega, t_k) \to \bar{x}$ where $\bar{x} \neq 0$. Consider the omega-limit set with respect to the flow $\{\tilde{\tau}_t\}$ of the point $(\omega, 1) \in \Omega \times \mathbb{R}$. This set is compact and invariant, and contains the point $(\bar{\omega}, \bar{x})$. It follows that $\varphi(\bar{\omega}, t)\bar{x}$ is bounded for all $t \in \mathbb{R}$; in fact, $\varphi(\bar{\omega}, t)\bar{x} \leqslant \frac{c}{\delta}$ $(t \in \mathbb{R})$. However, the only bounded solution of $(2_{\bar{\omega}})$ is the zero solution, hence $\bar{x} = 0$. This contradiction shows that $\varphi(\omega, t) \to 0$ as $t \to \infty$.

Next note that, if $\omega \in \Omega$, then there exists t_ω such that, if $t \geqslant t_\omega$, then $\varphi(\omega, t) < 1/2$. There is a neighborhood U_ω of ω in Ω such that, if $\bar{\omega} \in U_\omega$, then $\varphi(\bar{\omega}, t_\omega) < 1/2$. Choose $\omega_1, \ldots, \omega_r \in \Omega$ so that $\Omega = U_{\omega_1} \cup \cdots \cup U_{\omega_r}$. Write $U_i = U_{\omega_i}$, $t_i = t_{\omega_i}$ $(1 \leqslant i \leqslant r)$, and set $T = \max\{t_1, \ldots, t_r\}$. If $\bar{\omega} \in \Omega$ and $\bar{\omega} \in U_k$, then $\varphi(\bar{\omega}, t_j + t_k) = \varphi(\tau_{t_j}(\bar{\omega}), t_k)\varphi(\bar{\omega}, t_j) < (\frac{1}{2})^2$. This argument can be iterated to obtain the following: let $\alpha = \frac{\ln 2}{T}$ and $K = 2\sup\{\varphi(\omega, t) \mid \omega \in \Omega,\ 0 \leqslant t \leqslant T\}$; then $\varphi(\omega, t) \leqslant K\mathrm{e}^{-\alpha t}$ $(t \geqslant 0)$. We have shown that $\varphi(\omega, t)$ decays to zero in a uniform exponential way as $t \to \infty$. Now, the exponential decay has the consequence that, if $\omega \in \Omega$, then

$$\limsup_{t\to\infty} \frac{1}{t} \int_0^t f(\omega \cdot s)\,\mathrm{d}s \leqslant -\alpha. \tag{$*$}$$

We claim that condition $(*)$ is inconsistent with the hypothesis that $\int_\Omega f\,\mathrm{d}\nu_0 = 0$.

To see this, observe first that there exist ergodic measures ν_1, ν_2 on Ω such that $\int_\Omega f\,\mathrm{d}\nu_1 \leqslant 0$ and $\int_\Omega f\,\mathrm{d}\nu_2 \geqslant 0$ (these ergodic measures may coincide: $\nu_1 = \nu_2 = \nu$, in which case $\int_\Omega f\,\mathrm{d}\nu = 0$). This follows from the Choquet theory [131] applied to the weak-$*$ compact convex subset I of invariant measures on Ω. In fact, the invariant measure ν_0 can be expressed as an integral over I with respect to a measure H concentrated on the set E of ergodic measures, in such a way that $\int_\Omega f\,\mathrm{d}\nu_0 = \int_E (\int_\Omega f\,\mathrm{d}\nu)\,\mathrm{d}H(\nu)$. So if, say, $\int_\Omega f\,\mathrm{d}\nu > 0$ for all ergodic measures ν, then $\int_\Omega f\,\mathrm{d}\nu_0 > 0$, and similarly if $\int_\Omega f\,\mathrm{d}\nu < 0$ for all ergodic measures ν. This proves the existence of the measures ν_1, ν_2.

Now, if $\int_\Omega f\,\mathrm{d}\nu_2 \geqslant 0$, then there exists a set $\Omega_2 \subset \Omega$ with $\nu_2(\Omega_2) = 1$ such that, if $\omega_2 \in \Omega_2$, then

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t f(\omega_2 \cdot s)\,\mathrm{d}s \geqslant 0,$$

in contradiction with $(*)$.

Recapitulating, we have shown that, if condition (i) does not hold, then there does not exist a constant c such that $\int_0^t f(\omega \cdot s)\,\mathrm{d}s \leqslant c$ for all $\omega \in \Omega$, $t \geqslant 0$. We now set $\Omega_N = \{\omega \in \Omega \mid \int_0^t f(\omega \cdot s)\,\mathrm{d}s \leqslant N$ for all $t \geqslant 0\}$. Then Ω_N is closed $(N = 1, 2, \ldots)$. If for some N, Ω_N contains a set U which is open in Ω, then there are times $t_1 > 0, \ldots, t_r > 0$ such that $\tau_{t_1}(U) \cup \cdots \cup \tau_{t_r}(U) = \Omega$. It follows that $\int_0^t f(\omega \cdot s)\,\mathrm{d}s$ is bounded above by a uniform constant for all $\omega \in \Omega$, $t \geqslant 0$. But we know that this is not possible. We conclude that $\bigcup_{N=1}^\infty \Omega_N$ has first category in Ω.

Let $\Omega_1 = \Omega \setminus \bigcup_{N=1}^\infty \Omega_N$. If ω is in the residual set Ω_1, then $\limsup_{t\to\infty} \int_0^t f(\omega \cdot s)\,\mathrm{d}s = \infty$. We apply reasoning similar to the above to obtain residual sets $\Omega_2, \Omega_3, \Omega_4 \subset \Omega$ for which the remaining oscillation conditions hold. Then the residual set $\Omega_* = \bigcap_{i=1}^4 \Omega_i$ satisfies the oscillation conditions (ii). □

One of the first proofs of the equivalence of condition (i) and the existence of a point ω_0 for which $\int_0^t f(\omega \cdot s)\,\mathrm{d}s$ is bounded was published in ([63], Theorem 14.11); we have repeated this proof. The fact that condition (ii) follows from the hypotheses of Lemma 3.1 was proved in [82]. There the condition that $\int_\Omega f\,\mathrm{d}\nu_0 = 0$ for some invariant measure ν_0 is substituted by the equivalent condition that, for some point $\omega \in \Omega$ and some sequence t_k such that $|t_k| \to \infty$, one has $\lim_{k\to\infty} \frac{1}{t_k}\int_0^{t_k} f(\omega \cdot s)\,\mathrm{d}s = 0$.

At several points in the discussion, we will apply a result proved by Cameron [25] in 1936 for almost periodic linear differential systems. It was later generalized to linear differential system with Birkhoff recurrent coefficients [41]. More recently, special cases of Cameron's theorem have been rediscovered by several authors.

THEOREM 3.2 (Cameron). *Suppose that* $(\Omega, \mathbb{R})$ *is minimal and that* $n \geqslant 1$. *Let* $A : \Omega \to \mathbb{M}_n$ *be a continuous function. Suppose that each* $\omega \in \Omega$ *has the property that all solutions of Eq.* (3.1_ω):

$$x' = A(\omega \cdot t)x$$

are bounded. Then there is a continuous and continuously invertible map $L : \Omega \to \mathrm{GL}(n, \mathbb{R})$ *with the following properties.*

- *L has symmetric values*: $L(\omega)^T = L(\omega)$ *for all* $\omega \in \Omega$.
- *The map* $\omega \to \frac{\mathrm{d}}{\mathrm{d}t} L(\omega \cdot t)|_{t=0}$ *is well-defined and continuous.*
- *The change of variables* $x = L(\omega \cdot t)y$ *takes* (3.1_ω) *to the form*

  $$y' = B(\omega \cdot t)y$$

  where $B : \Omega \to \mathbb{M}_n$ *is continuous and has antisymmetric values*: $B(\omega)^T = -B(\omega)$ *for all* $\omega \in \Omega$.
- *If A takes values in* $\mathrm{sl}(2, \mathbb{R})$, *then L takes values in* $\mathrm{SL}(2, \mathbb{R})$.

For a proof of this theorem see [41]. It makes use of Cameron's original idea and some results of Ellis concerning the structure of distal extensions of minimal flows.

We return to the case $n = 2$. Let $(\Omega, \mathbb{R})$ be a minimal flow. In what follows we will usually assume in addition that $(\Omega, \mathbb{R})$ is almost periodic. Let $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ be a continuous map. Our goal is to analyze the minimal subsets of the projective flow $(\Sigma, \mathbb{R})$ defined by Eqs. (3.1_ω). The first step is to count them. We begin with a strengthened version of a theorem of Sacker and Sell [139].

PROPOSITION 3.3. *Let* $(\Omega, \mathbb{R})$ *be a minimal almost periodic flow, let* $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ *be continuous, and let* $(\Sigma, \mathbb{R})$ *be the projective flow defined by Eqs.* (3.1_ω). *Suppose that* Σ *contains* $k \geqslant 3$ *distinct minimal sets. Then there is a continuous, continuously invertible* *matrix function* $L:\Omega \to \mathrm{SL}(2,\mathbb{R})$ *such that the change of variables* $y = L(\omega\cdot t)x$ *takes Eqs.* (3.1_ω) *into the form*

$$y' = \begin{pmatrix} 0 & -b_0 \\ b_0 & 0 \end{pmatrix} y \quad (\omega \in \Omega)$$

where $b_0 \in \mathbb{R}$ *is a constant.*

We include a proof of this proposition since it illustrates several simple but useful techniques.

PROOF. We first show that, for each $\omega \in \Omega$, the fundamental matrix solution $\Phi_\omega(t)$ of (3.1_ω) is bounded. For this, let M_1, M_2, M_3 be three distinct minimal subsets of Σ. Fix $\omega \in \Omega$, and let $l_1, l_2, l_3 \in \mathbb{P}$ be points such that $(\omega, l_i) \in M_i$, $1 \leqslant i \leqslant 3$. Such points can be found because $(\Omega, \mathbb{R})$ is minimal, hence the projection $\pi(M_i)$ equals Ω $(1 \leqslant i \leqslant 3)$.

Let d be a metric on $\mathbb{P}$. Note that, if $i \neq j$, then (ω, l_i) and (ω, l_j) form a distal pair in the sense that $\inf_{t\in\mathbb{R}} d(\Phi_\omega(t)l_i, \Phi_\omega(t)l_j) > 0$. This is because the orbits $\{\hat{\tau}_t(\omega, l_i) \mid t \in \mathbb{R}\}$ lie in the mutually disjoint minimal sets M_i $(1 \leqslant i \leqslant 3)$. Let $\bar{x}_i \in l_i$ be a vector of norm 1, and set $x_i(t) = \Phi_\omega(t)\bar{x}_i$ $(1 \leqslant i \leqslant 3)$.

Suppose for contradiction that $x_1(t)$ is unbounded. Then there exists a sequence $(t_k) \subset \mathbb{R}$ such that $|t_k| \to \infty$ and $|x_1(t_k)| \geqslant k$. Let $\Psi(t)$ be the matrix solution of (3.1_ω) whose columns are $x_1(t)$ and $x_2(t)$. By Liouville's formula, $\det \Psi(t) = c = \mathit{constant} \neq 0$, and it follows from the distallity condition on (ω, l_1) and (ω, l_2) that $\lim_{k\to\infty} x_2(t_k) = 0$. In a similar way, one proves that $\lim_{k\to\infty} x_3(t_k) = 0$.

Now, however, we let $\Psi_*(t)$ be the matrix solution of (3.1_ω) whose columns are $x_2(t)$ and $x_3(t)$. Then $\det \Psi_*(t) = c_* = \text{constant} \neq 0$ for all $t \in \mathbb{R}$. But $\lim_{k\to\infty} \Psi_*(t_k) = 0$. This contradiction proves that $x_1(t)$ is bounded. In a similar way, one proves that $x_2(t)$ is bounded (and also $x_3(t)$ for that matter). Since a generic solution of (3.1_ω) is a linear combination of $x_1(t)$ and $x_2(t)$, we see that $\Phi_\omega(t)$ is bounded.

Let us apply Theorem 3.2 to find a continuous, continuously invertible function $L:\Omega \to \mathrm{SL}(2,\mathbb{R})$ such that $\omega \mapsto \frac{\mathrm{d}}{\mathrm{d}t} L(\omega\cdot t)|_{t=0}$ is well-defined and continuous, and such that the change of variables $x = L(\omega\cdot t)y$ brings Eq. (3.1_ω) to the form

$$y' = \begin{pmatrix} 0 & -b(\omega\cdot t) \\ b(\omega\cdot t) & 0 \end{pmatrix} y \tag{3.3_ω}$$

where $b:\Omega \to \mathbb{R}$ is continuous. Let ν be an ergodic measure on Ω, and let $b_0 = \int_\Omega b(\omega)\,\mathrm{d}\nu(\omega)$. For each $\omega \in \Omega$, consider the quantity

$$\int_0^t \big(b(\omega\cdot s) - b_0\big)\,\mathrm{d}s = \int_0^t b(\omega\cdot s)\,\mathrm{d}s - b_0 t.$$

According to Lemma 3.1 this quantity satisfies exactly one of the following conditions.

(α) There exists a continuous function $B:\Omega \to \mathbb{R}$ such that $B(\omega\cdot t) - B(\omega) = \int_0^t (b(\omega\cdot s) - b_0)\,\mathrm{d}s$ for all $\omega \in \Omega$ and $t \in \mathbb{R}$.

(β) There is a residual set $\Omega_* \subset \Omega$ such that the oscillation conditions (ii) of Lemma 3.1 hold.

Suppose first that (α) holds. Make the change of variable

$$y = \begin{pmatrix} \cos B(\omega \cdot t) & -\sin B(\omega \cdot t) \\ \sin B(\omega \cdot t) & \cos B(\omega \cdot t) \end{pmatrix} z$$

in Eq. (3.3_ω), and note that, in the z-variable, Eqs. (3.1_ω) take the form

$$z' = \begin{pmatrix} 0 & -b_0 \\ b_0 & 0 \end{pmatrix} z.$$

So in this case Proposition 3.3 is proved.

Suppose the second possibility (β) holds. It turns out that, in this case, we cannot have $k \geqslant 3$. We indicate how this can be proved. Note that the circle group $\mathbb{T} = \mathbb{R}/\pi\mathbb{Z}$ acts on $\mathbb{P} = \mathbb{R}/\pi\mathbb{Z}$ by addition. Hence $\mathbb{T}$ acts on Σ in the following way: if $(\omega, l) \in \Sigma$ and $g \in \mathbb{T}$, then $g \cdot (\omega, l) = (\omega, g + l)$.

Let $(\Sigma, \{\hat{\tau}_t\})$ be the projective flow defined by Eqs. (3.3_ω). Then $\mathbb{T}$ commutes with $\{\hat{\tau}_t\}$ in the sense that, if $g \in \mathbb{T}$, then $g \cdot \hat{\tau}_t(\omega, l) = \hat{\tau}_t(g \cdot (\omega, l))$. Now, if $M \subset \Sigma$ is minimal, then $g \cdot M = \{g \cdot m \mid m \in M\}$ either coincides with M or is disjoint from M. Consider the subgroup G_0 of $\mathbb{T}$ defined as follows: $G_0 = \{g \in \mathbb{T} \mid g \cdot M = M\}$. Since $k > 1$, G_0 must be finite; let G_0 have r elements. Then M is an r-cover of Ω. It can be shown that $(M, \{\tau_t\})$ is an almost periodic minimal set [42,139].

Now however, let $\pi_2 : \Sigma \to \mathbb{P}$ be the projection on the second factor. Using almost periodicity of $(M, \mathbb{R})$, we see that the function

$$t \mapsto -b_0 t + \int_0^t b(\omega \cdot s)\,\mathrm{d}s \mod \pi$$

is almost periodic. Using an old theorem of Bohr (see Fink [54], Proposition 6.7), we see that $\int_0^t (b(\omega \cdot s) - b_0)\,\mathrm{d}s$ is an almost periodic function, hence is bounded. This last condition contradicts (β), so the proof of Proposition 3.3 is complete. In fact we have shown that, if (β) holds, then $k = 1$ for Eqs. (3.3_ω). That is, $(\Sigma, \mathbb{R})$ is minimal. □

REMARKS 3.4. If $(\Omega, \mathbb{R})$ is assumed to be minimal but not necessarily almost periodic, then we can only prove a weaker version of Proposition 3.3. We indicate what can be shown. Suppose that $k \geqslant 3$. We can still apply Cameron's theorem and reduce Eqs. (3.1_ω) to the skew-symmetric form (3.3_ω). The group $\mathbb{T} = \mathbb{R}/\pi\mathbb{Z}$ commutes with the flow on Σ defined by Eqs. (3.3_ω), so if $M \subset \Sigma$ is minimal, and if $G_0 = \{g \in \mathbb{T} \mid g \cdot M = M\}$, then G_0 is a finite subgroup of $\mathbb{T}$. This shows, incidentally, that $k = \infty$ because two points $g_1, g_2 \in \mathbb{T}$ with $g_1 - g_2 \notin G_0$ give rise to distinct minimal sets $M_i = g_i \cdot M$ $(i = 1, 2)$. Thus one has the so-called 1–2–∞ theorem [139].

Suppose now that G_0 contains r elements. Then each minimal subset $M \subset \Sigma$ is an r-cover of Ω, and in fact a finite Abelian group extension of Ω. In these circumstances, it seems reasonable to look for a change of variable $y = L_1(\omega \cdot t)z$ which takes Eqs. (3.3_ω)

to constant-coefficient form. However, we have not been able to prove that such a change of variables always exists.

Let us now turn to the case $k = 2$, where k is the number of distinct minimal subsets of Σ. When the coefficient matrix $A(\cdot)$ in (3.1) is 2π-periodic, the condition $k = 2$ is equivalent to the statement that the corresponding family of Eqs. (3.1_ω) has an exponential dichotomy. In this situation, the projective flow is isomorphic to that determined by the system $x' = \begin{pmatrix} a & 0 \\ 0 & -a \end{pmatrix} x$. Here the nonzero constant a is interpreted as a 2π-periodic function. We will see that other possibilities are present when (3.1) has an almost periodic coefficient $A(\cdot)$.

Unless otherwise stated, $(\Omega, \mathbb{R})$ will denote a minimal almost periodic flow. Let $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ be continuous, and let $(\Sigma, \mathbb{R})$ be the projective flow defined by the corresponding family of Eqs. (3.1_ω). Suppose that $(\Sigma, \mathbb{R})$ contains exactly two minimal sets.

Let us first note that, in this case, each Eq. (3.1_ω) admits an unbounded solution. For suppose that this is not the case, and that, for some $\omega \in \Omega$, the fundamental matrix solution $\Phi_\omega(t)$ of Eq. (3.1_ω) is bounded: $|\Phi_\omega(t)| \leqslant c < \infty$ for all $t \in \mathbb{R}$. If $\bar{\omega} \in \Omega$, let $(t_k) \subset \mathbb{R}$ be a sequence such that $\omega \cdot t_k \to \bar{\omega}$. Passing to a subsequence, we can assume that $\Phi_\omega(t + t_k)$ converges, uniformly on compact subsets of $\mathbb{R}$, to a matrix solution $\Psi(t)$ of Eq. $(1_{\bar{\omega}})$. Since $\det \Psi(t) = 1$ for all $t \in \mathbb{R}$, $\Psi(t)$ is an invertible matrix solution of $(1_{\bar{\omega}})$, and moreover $|\Psi(t)| \leqslant c$. It follows that all solutions of $(1_{\bar{\omega}})$ are bounded, as well.

Now however, we can apply Cameron's theorem to reduce Eqs. (3.1_ω) to the form (3.3_ω). Following the analysis of the family (3.3_ω) which was carried out in the proof of Proposition 3.3, we see that either $k = 1$ or $k = \infty$. So indeed each Eq. (3.1_ω) admits an unbounded solution.

It is of course possible that the family (3.1_ω) admits an exponential dichotomy. In this case, all solutions of all Eqs. (3.1_ω) are unbounded. However, we will encounter other, more interesting families of Eqs. (3.1_ω) for which $k = 2$.

First we consider some a priori properties of the minimal subsets of Σ when $(\Omega, \mathbb{R})$ is minimal and almost periodic, and $k = 2$. We begin with some terminology.

DEFINITIONS 3.5. Let Ω be a compact metric space with distance function d, and let $(\Omega, \mathbb{R})$ be a flow. Say that two points $\omega_1, \omega_2 \in \Omega$ form a *distal pair* if there exists $\delta > 0$ such that $d(\omega_1 \cdot t, \omega_2 \cdot t) \geqslant \delta$ for all $t \in \mathbb{R}$. Say that ω_1, ω_2 form a *proximal pair* if $\omega_1 \neq \omega_2$ and there exists a sequence $(t_k) \subset \mathbb{R}$ such that $\lim_{k \to \infty} d(\omega_1 \cdot t_k, \omega_2 \cdot t_k) = 0$. Say that $(\Omega, \mathbb{R})$ is *distal* if every pair $\omega_1, \omega_2 \in \Omega$ with $\omega_1 \neq \omega_2$ is distal, and say that $(\Omega, \mathbb{R})$ is *proximal* is every pair $\omega_1, \omega_2 \in \Omega$ with $\omega_1 \neq \omega_2$ is proximal. Let $(\Sigma, \mathbb{R})$ be another flow where Σ is a metric space, and let $\pi : \Sigma \to \Omega$ be a flow homomorphism. Say that Σ is a *distal extension* of Ω if whenever $\pi(\sigma_1) = \pi(\sigma_2)$ and $\sigma_1 \neq \sigma_2$, the pair (σ_1, σ_2) is distal with respect to the flow $(\Sigma, \mathbb{R})$. Similarly, say that Σ is a *proximal extension* of Ω if whenever $\pi(\sigma_1) = \pi(\sigma_2)$ and $\sigma_1 \neq \sigma_2$, the pair (σ_1, σ_2) is proximal with respect to the flow $(\Sigma, \mathbb{R})$.

In the context of systems of ordinary differential equations, the distallity concept is related to the well-known Favard property [52,158] and to properties of separatedness of the solutions. See [24,139].

PROPOSITION 3.6. *Let* $(\Omega, \mathbb{R})$ *be an almost periodic minimal flow, and let* $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ *be continuous. Suppose that the projective flow* $(\Sigma, \mathbb{R})$ *defined by Eqs.* (3.1_ω)

admits $k = 2$ minimal sets. Then each such minimal set $M \subset \Sigma$ is an almost automorphic extension of Ω.

For the definition of almost automorphic extension, see Section 2. It is of course understood that the flow homomorphism defining the extension is the projection $\pi : \Sigma \to \Omega$. Proposition 3.6 implies that there is a residual subset $\Omega_0 \subset \Omega$ such that, if $\omega \in \Omega_0$, then $\pi^{-1}(\omega) \cap M$ contains exactly one point. Of course, the possibility that $\Omega_0 = \Omega$ is not excluded.

PROOF. Let M_1 and M_2 be the minimal subsets of Σ. Let us first suppose that, for some $\omega \in \Omega$, the fiber $\pi^{-1}(\omega) \cap M_1$ contains two distinct points m_0, m_1. Further, let $m_2 \in M_2$ be a point such that $\pi(m_2) = \omega$. Let $m_i = (\omega, l_i)$, then choose $\bar{x}_i \in l_i$ with $|\bar{x}_i| = 1$, and set $x_i(t) = \Phi_\omega(t)\bar{x}_i$ $(i = 0, 1, 2)$. Note that (m_0, m_2) and (m_1, m_2) are distal pairs in Σ because M_1 and M_2 are compact and disjoint.

Suppose that $x_2(t)$ is unbounded, so that there is a sequence $(t_k) \subset \mathbb{R}$ such that $\lim_{k\to\infty} |x_2(t_k)| = \infty$. Let $\Psi_0(t)$ be the matrix solution of (3.1_ω) whose columns are $x_0(t)$ and $x_2(t)$. By Liouville's formula, $\det \Psi_0(t) = \det \Psi_0(0) \neq 0$ for all $t \in \mathbb{R}$. Since (m_0, m_2) is a distal pair, it must be the case that $\lim_{k\to\infty} x_0(t_k) = 0$. In an analogous way, we can conclude that $\lim_{k\to\infty} x_1(t_k) = 0$. Now, however, if $\Psi(t)$ is the matrix solution of (3.1_ω) whose columns are $x_0(t)$ and $x_1(t)$, then $0 \neq \det \Psi(0) = \lim_{k\to\infty} \det \Psi(t_k) = 0$, a contradiction. We conclude that $x_2(t)$ is bounded.

If $x_0(t)$ is also bounded, then the matrix solution $\Psi_0(t)$ is bounded. However, we have seen that this possibility is inconsistent with the hypothesis that $k = 2$. Therefore $x_0(t)$ is unbounded. Thus there is a sequence $(t_k) \subset \mathbb{R}$ such that $\lim_{k\to\infty} |x_0(t_k)| = \infty$. It follows that $x_2(t_k) \to 0$ as $k \to \infty$.

Suppose for contradiction that there is a point $m_3 \neq m_2$ in M_2 such that $\pi(m_3) = \omega$. Let $m_3 = (\omega, l_3)$, choose $\bar{x}_3 \in l_3$ such that $|\bar{x}_3| = 1$, and set $x_3(t) = \Phi_\omega(t)\bar{x}_3$. Reasoning as in the first two paragraphs of the proof, we see that $x_3(t_k) \to 0$ as $k \to \infty$. However, if we form the matrix solution of (3.1_ω) whose columns are $x_2(t)$ and $x_3(t)$, and if we apply Liouville's formula along the sequence (t_k), we obtain a contradiction. We conclude that m_2 is the unique point in the fiber $\pi^{-1}(\omega) \cap M_2$. This implies that M_2 is an almost automorphic extension of Ω.

We must still show that M_1 is an almost automorphic extension of Ω. If this is not the case, then for each $\omega \in \Omega$, the fiber $\pi^{-1}(\omega) \cap M_1$ contains at least two points. Arguing as above, we see that $\pi : M_2 \to \Omega$ is injective (actually a homeomorphism). Let $m_2 = (\omega, l_2) \in M_2$, and let $\bar{x}_2 \in l_2$ satisfy $|\bar{x}_2| = 1$. Carrying out the reasoning of the first two paragraphs of the proof, we see that $x_2(t) = \Phi_\omega(t)\bar{x}_2$ is bounded.

At this point, let us return to Eq. (3.3_ω) in Section 2. Letting $f : \Sigma \to \mathbb{R}$ be the function in that equation, and restricting f to M_2, we see that

$$\ln\left|x_2(t)\right| = \int_0^t f\left(\hat{\tau}(m_2)\right) \mathrm{d}s$$

for each $m_2 \in M_2$. Now, $(M_2, \mathbb{R})$ is a minimal flow and, according to the previous paragraph, $\int_0^t f(\hat{\tau}(m_2))\,\mathrm{d}s$ is bounded above for all $m_2 \in M_2$. It follows from the oscillation

Lemma 3.1 that $\int_0^t f(\hat{\tau}(m_2))\,\mathrm{d}s$ is uniformly bounded (above and below) for $m_2 \in M_2$, $t \in \mathbb{R}$. In particular, $x_2(t)$ is bounded away from zero for all $m_2 \in M_2$.

Again let $\omega \in \Omega$, let $m_0, m_1 \in M_1 \cap \pi^{-1}(\omega)$, and let $\Psi_0(t)$ be the matrix solution of (3.1_ω) whose columns are $x_0(t)$ and $x_2(t)$. Using the distallity of the pair (m_0, m_2), we see that $\Psi_0(t)$ is bounded. This is a contradiction, so we see that M_1 is an almost automorphic extension of Ω.

Until now, we have worked under the hypothesis that at least one fiber of M_1 contains two (or more) distinct points. To complete the proof of Proposition 3.6, we must examine the case that all fibers $\pi^{-1}(\omega) \cap M_1$ contain just one point. However, if this is true, and if M_2 is not an almost automorphic extension of Ω, then each fiber $\pi^{-1}(\omega) \cap M_2$ contains two or more points. We can thus repeat the reasoning just given; we obtain a contradiction; we then conclude that M_2 is an almost automorphic extension of Ω, after all. This conclude the proof of Proposition 3.6. □

We consider some examples in which $k = 2$. We will see that interesting phenomena are compatible with this hypothesis, which have no analogue in the periodic case. We begin with a class of simple equations which still have some interesting features. Let $(\Omega, \mathbb{R})$ be an almost periodic minimal flow, and let ν be the unique ergodic measure on Ω. Let $a : \Omega \to \mathbb{R}$ be a continuous function with mean value zero, that is to say $\int_\Omega a\,\mathrm{d}\nu = 0$. Let $C_0(\Omega)$ be the class of all such continuous functions on Ω. Next, let $a \in C_0(\Omega)$ be a function such that for some (hence all) $\omega \in \Omega$, the integral $\int_0^t a(\omega \cdot s)\,\mathrm{d}s$ is unbounded.

Consider the family of linear differential systems

$$x' = \begin{pmatrix} a(\omega \cdot t) & 0 \\ 0 & -a(\omega \cdot t) \end{pmatrix} x, \quad x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2. \tag{3.4_ω}$$

Letting $l_i \in \mathbb{P}$ be the x_i-axis $(i = 1, 2)$, we see that there are two minimal sets in Σ, namely $M_i = \{(\omega, l_i) \mid \omega \in \Omega\}$, $i = 1, 2$. There are no other minimal subsets of Σ because, if there were, then all solutions of Eqs. (3.4_ω) would be bounded, and that is not true. It is clear that this example shows that the hypothesis $k = 2$ is compatible with the vanishing of the Lyapunov exponent of the family (3.4_ω).

Actually, this class of examples can be divided into two subclasses, as follows. We first consider two subsets $\mathcal{C}_1$ and $\mathcal{C}_2$ of $C_0(\Omega)$ defined as follows: $\mathcal{C}_1 = \{a \in C_0(\Omega) \mid$ there exists a ν-measurable but noncontinuous function $A : \Omega \to \mathbb{R}$ such that $A(\omega \cdot t) - A(\omega) = \int_0^t a(\omega \cdot s)\,\mathrm{d}s$ for all $\omega \in \Omega,\ t \in \mathbb{R}\}$ and $\mathcal{C}_2 = \{a \in C_0(\Omega) \mid \int_0^t a(\omega \cdot s)\,\mathrm{d}s$ in unbounded for some $\omega \in \Omega$, and there is no measurable function $A : \Omega \to \mathbb{R}$ such that $A(\omega \cdot t) - A(\omega) = \int_0^t a(\omega \cdot s)\,\mathrm{d}s$ a.e. in $\omega\}$. It can be shown that both $\mathcal{C}_1$ and $\mathcal{C}_2$ are dense in $C_0(\Omega)$, though $\mathcal{C}_1$ is "bigger" in the sense that it is residual [74].

Next we note that the projective flow $(\Sigma, \mathbb{R})$ of the family (3.4_ω) can be explicitly described because, if $\theta(t)$ is the polar angle of a solution $x(t)$ of (3.4_ω), and if $u(t) = \cot\theta(t)$, then

$$u' = 2a(\omega \cdot t)u.$$

Suppose now that $a \in \mathcal{C}_1$. For each $\theta \in (0, \pi)$, the set $\{(\omega, \theta_\omega) \mid \cot\theta_\omega = \cot \mathrm{e}^{2A(\omega)}, \omega \in \Omega\}$ defines a measurable invariant section of Σ. This implies that, for each $\theta \in (0, \pi)$, there is an ergodic measure μ_θ on Σ defined as follows:

$$\int_\Sigma h\, \mathrm{d}\mu_\theta = \int_\Omega h(\omega, \theta_\omega)\, \mathrm{d}\nu(\omega), \qquad h \in C(\Sigma).$$

That is, the flow $(\Sigma, \mathbb{R})$ laminates into measurable invariant sections which define ergodic measures on Σ.

On the other hand, if $a \in \mathcal{C}_2$, then it can be shown that there are only two ergodic measures μ_1 and μ_2, which are supported on M_1 and M_2 respectively. We leave the proof as an exercise for the interested reader.

Let us now consider a class of examples of almost periodic Eqs. (3.1_ω) for which $k = 2$, and for which one of the minimal sets $M \subset \Sigma$ is almost automorphic but not almost periodic. We will see that examples exhibiting such minimal sets permit one to answer certain questions regarding linear nonhomogeneous almost periodic differential equations which do not satisfy the Favard separation property.

Let $(\Omega, \mathbb{R})$ be an almost periodic minimal flow, and let $a, b : \Omega \to \mathbb{R}$ be continuous functions. Consider the family of linear equations

$$x' = \begin{pmatrix} \frac{1}{2}a(\omega \cdot t) & b(\omega \cdot t) \\ 0 & -\frac{1}{2}a(\omega \cdot t) \end{pmatrix} x, \quad x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2. \tag{3.5_ω}$$

Introducing the polar angle θ in $\mathbb{R}^2$, and setting $u = \cot\theta$, we find that

$$u' = a(\omega \cdot t)u + b(\omega \cdot t). \tag{3.6_ω}$$

Let $(\Sigma, \mathbb{R})$ be the projective flow defined by Eqs. (3.5_ω). Note that, if $l_1 \in \mathbb{P}$ denotes the x_1-axis, then the set $M_0 = \{(\omega, l_1) \mid \omega \in \Omega\}$ is a minimal subset of Σ. The complement $\Sigma \setminus M_0$ is parameterized by points (ω, θ) where $0 < \theta < \pi$, or equivalently by points (ω, u) where $-\infty < u < \infty$. Thus we can study the projective flow $(\Sigma, \mathbb{R})$ by studying solutions of the family (3.6_ω) of linear nonhomogeneous equations, and vice-versa.

Let ν be the unique invariant measure on Ω, and let $a_0 = \int_\Omega a\, \mathrm{d}\nu$. It is well-known that, if $a_0 \neq 0$, then each Eq. (3.6_ω) admits a unique almost periodic solution. For example, if $a_0 > 0$, then

$$u_\omega(t) = \int_t^\infty b(\omega \cdot s) \mathrm{e}^{\int_s^t a(\omega \cdot r)\, \mathrm{d}r}\, \mathrm{d}s$$

is the unique almost periodic solution of (3.6_ω). Of course, we are dealing here with a simple case of a general theory regarding the existence, uniqueness, and recurrence properties of bounded solutions of a linear nonhomogeneous differential system whose linear part admits an exponential dichotomy.

Our interest here is in the case when $a_0 = 0$. It is convenient to consider two subcases. First, suppose that $\int_0^t a(\omega \cdot s)\, \mathrm{d}s$ is bounded for some (hence all) $\omega \in \Omega$. One then checks that, if some equation $(3.6_{\bar{\omega}})$ admits a bounded solution, then for every $\omega \in \Omega$, all solutions of (3.6_{ω}) are almost periodic. One can put this trivial observation in the context of the general Favard theory concerning bounded solutions of linear nonhomogeneous almost periodic differential systems in dimension n [52]. To see this, note that the family (3.6_{ω}) satisfies the Favard separation condition: if $\omega \in \Omega$ and if $u_1(t), u_2(t)$ are two bounded solutions of (3.6_{ω}), then $\inf_t |u_1(t) - u_2(t)| > 0$. The Favard theory then states that, if one Eq. $(6_{\bar{\omega}})$ admits a bounded solution, then every Eq. (3.6_{ω}) admits an almost periodic solution. In the one-dimensional case $n = 1$, this implies that all solutions of (3.6_{ω}) are almost periodic $(\omega \in \Omega)$.

We are going to consider the second case, which is when $\int_0^t a(\omega \cdot s)\,\mathrm{d}s$ is unbounded for some (hence all) $\omega \in \Omega$. In this situation, Eqs. (3.6_{ω}) do not all satisfy the Favard separation property (this follows from Lemma 3.1). For a long time it was not known if the existence of a bounded solution of some Eq. $(6_{\bar{\omega}})$ implies that Eqs. (3.6_{ω}) admit almost periodic solutions. The question was settled in the negative by examples of [158] and [73]. It turn out that, if some Eq. $(6_{\bar{\omega}})$ is assumed to have a bounded solution, then some Eq. (3.6_{ω}) (perhaps not the original equation) admits an almost automorphic solution; however this almost automorphic solution need not to be almost periodic. This follows from the discussion and the example in [73].

In a recent paper [126], Ortega and Tarallo carried out a systematic analysis of examples like those in [158] and [73]. They developed techniques which permit one to construct examples of "non-Favard type" for all almost periodic flows $(\Omega, \mathbb{R})$. In fact, they prove a result ([126], Theorem 2) which, for the one-dimensional family (3.6_{ω}), has the following consequence.

THEOREM 3.7. *Suppose that, for some $\bar{\omega} \in \Omega$, there holds*

$$\lim_{t \to -\infty} \int_0^t a(\bar{\omega} \cdot s)\,\mathrm{d}s = \lim_{t \to \infty} \int_0^t a(\bar{\omega} \cdot s)\,\mathrm{d}s = -\infty.$$

Then there exists a continuous function $b : \Omega \to \mathbb{R}$ such that each Eq. (3.6_{ω}) admits a bounded solution, and for which no Eq. (3.6_{ω}) admits an almost periodic solution.

We will not prove this theorem here, instead we refer to ([126], Section 6-7). There a particular concept of weak solution of an n-dimensional linear nonhomogeneous almost periodic system is developed. For related considerations see [127].

The $a(\cdot)$-term of the example in [158] and [73] satisfies the hypothesis of Theorem 3.7 for some $\bar{\omega} \in \Omega$. In fact, [158] makes use of a classical quasi-periodic example of Bohr [21], while [73] applies a limit periodic example of Conley and Miller [27].

We now extend Theorem 3.7 in that we discuss the recurrence properties of the bounded solutions of Eqs. (3.6_{ω}). We follow the discussion in [73]. We continue to assume that $k = 2$.

PROPOSITION 3.8. *Suppose that $\int_{\Omega} a\,\mathrm{d}\nu = 0$, and suppose that $\int_0^t a(\omega \cdot s)\,\mathrm{d}s$ is unbounded for some (hence all) $\omega \in \Omega$. Suppose further that some Eq. (3.6_{ω}) admits a bounded solution. Then there is a residual set $\Omega_* \subset \Omega$ such that, if $\omega \in \Omega_*$, then (3.6_{ω}) admits a unique bounded solution which is almost automorphic.*

Of course it is not excluded that the bounded solutions in this proposition are almost periodic.

PROOF. Let $\bar{\omega} \in \Omega$ be a point such that Eq. ($3.6_{\bar{\omega}}$) admits a bounded solution $\bar{u}(t)$. Let $\bar{\theta}(t) = \cot^{-1} u(t)$, and note that $\{(\tau_t(\bar{\omega}), \bar{\theta}(t)) \mid t \in \mathbb{R}\}$ is an orbit of the projective flow defined by Eqs. (3.5_ω). The orbit closure $\text{cls}\{(\tau_t(\bar{\omega}), \bar{\theta}(t)) \mid t \in \mathbb{R}\}$ is a compact invariant subset of Σ which is disjoint from the minimal set $M_0 = \{(\omega, l_1) \mid \omega \in \Omega\}$. It therefore contains a minimal set M_1, such that $M_1 \cap M_0 = \emptyset$.

Now, it is clear that, each Eq. (3.5_ω) admits an unbounded solution. In fact there exists $\omega \in \Omega$ for which each solution $x(t) = \binom{x_1(t)}{x_2(t)}$ satisfying $x_2(t) \equiv 0$ is unbounded, and therefore every Eq. (3.5_ω) admits an unbounded solution. Taking account of Proposition 3.3, we see that M_0 and M_1 are the only minimal subsets of Σ. By Proposition 3.6, M_1 is an almost automorphic extension of Ω. This means that there is a residual subset $\Omega_1 \subset \Omega$ such that, if $\omega_1 \in \Omega_1$, then the fiber $\pi^{-1}(\omega_1) \cap M_1$ contains exactly one point $(\omega_1, \bar{\theta}_1)$. One checks that, if $\hat{\tau}_t(\omega_1, \bar{\theta}_1) = (\tau_t(\omega), \theta_1(t))$, then $\theta_1(t)$ is an almost automorphic function. Hence $u_1(t) = \cot \theta_1(t)$ is an almost automorphic solution of (3.6_{ω_1}).

It follows from the oscillation Lemma 3.1 that there is a residual set $\Omega_2 \subset \Omega$ such that, if $\omega \in \Omega_2$, Eq. (3.6_ω) admits a unique bounded solution. Set $\Omega_* = \Omega_1 \cap \Omega_2$; then Ω_* satisfies the condition of Proposition 3.8. This completes the proof. □

Proposition 3.8 is of course applicable to all one-dimensional examples of Ortega–Tarallo type, and hence to the examples in [158] and [73]. Let us note that almost automorphicity is a more specific property than that of Besicovich almost periodicity. It was noted in [158] that a bounded solution of (3.6_ω) satisfies this last property; see that reference for the definition of almost periodicity in the Besicovich sense. The nature of Besicovich almost periodic functions has recently been discussed by Andres and his collaborators [6].

Examples of Ortega–Tarallo type correspond to two-dimensional families (3.5_ω) whose projective flows $(\Sigma, \mathbb{R})$ admit exactly two minimal subsets, one of which, say M_1, is an almost automorphic, non-almost periodic extension of Ω. There is a question concerning the structure of this minimal set M_1, which, so far as we know, has not been answered. In fact, it is not known (to us) if there exists a family (3.5_ω) for which the minimal set M_1 supports more than one invariant measure. In other words, we ask if there is a family (3.5_ω) for which the projection $\Omega_* = \{\omega \in \Omega \mid \pi^{-1}(\omega) \cap M_1$ contains just one point$\}$ of the set of all automorphic points of M_1 has zero ν-measure: $\nu(\Omega_*) = 0$. It is known that the minimal set of the family (3.5_ω) in [73] supports only one invariant measure; see [76].

Another question – probably more difficult – also awaits an answer. Namely, one would like to find a family of type (3.1_ω) for which $k = 2$, and for which both minimal subsets of Σ are almost automorphic, non-almost periodic extensions of Ω. Such a family (3.1_ω) cannot have the form (3.5_ω), because for families of the latter type the minimal set $M_0 = \{(\omega, l_1) \mid \omega \in \Omega\} \subset \Sigma$ is flow isomorphic to Ω via the projection π.

We continue to assume that $(\Omega, \mathbb{R})$ is an almost periodic minimal flow, and turn to the case when the projective flow $(\Sigma, \mathbb{R})$ defined by Eq. (3.1_ω) contains just one minimal set, i.e., $k = 1$. It will turn out that the projective flow can exhibit an ample range of interesting structures, most of which have no analogues in the periodic case. We divide the discussion into three subsections, according to the dynamical behavior of the solutions of Eq. (3.1_ω).

For want of better terminology, we label these subsections as follows: (A) the strongly elliptic case; (B) the weakly elliptic case; (C) the weakly hyperbolic case. There is actually a fourth case, that in which Eqs. (3.1_ω) admit an exponential dichotomy. In this case, the two minimal sets are defined by the "traces" in $\Omega \times \mathbb{P}$ of the Sacker–Sell subbundles $W_\pm$ which were discussed in Section 2. See [78] for the details. We will not discuss this case further.

(A) Strongly elliptic case

The condition we impose here is that all solutions of all Eqs. (3.1_ω) are bounded. This condition is consistent with the requirement that $k = 1$. We examine the various flows $(\Sigma, \mathbb{R})$ which can arise. We will see that Σ is itself a minimal set. However it can exhibit various structures which were already understood by Furstenberg about fifty years ago [55].

First of all, we apply Cameron's theorem 3.2 to find a continuous, continuously invertible function $L : \Omega \to \mathrm{SL}(2, \mathbb{R})$ such that $\omega \mapsto \frac{\mathrm{d}}{\mathrm{d}t} L(\omega \cdot t)|_{t=0}$ is continuous and such that the change of variables $x = L(\omega \cdot t)y$ brings Eqs. (3.1_ω) to the form

$$y' = \begin{pmatrix} 0 & -b(\omega \cdot t) \\ b(\omega \cdot t) & 0 \end{pmatrix} y, \tag{3.7_ω}$$

Let ν be the unique ergodic measure on Ω, and let $b_0 = \int_\Omega b \, \mathrm{d}\nu$. We consider two possibilities: (1) $\int_0^t (b(\omega \cdot t) - b_0) \, \mathrm{d}s$ is bounded for some (hence all) $\omega \in \Omega$; (2) $\int_0^t (b(\omega \cdot t) - b_0) \, \mathrm{d}s$ is unbounded for some (hence all) $\omega \in \Omega$.

If the first possibility is realized, there is a continuous function $B : \Omega \to \mathbb{R}$ such that $B(\omega \cdot t) - B(\omega) = \int_0^t (b(\omega \cdot t) - b_0) \, \mathrm{d}s$, and, as in the proof of Proposition 3.3, the further change of variables $y = \left(\begin{smallmatrix} \cos B(\omega \cdot t) & -\sin B(\omega \cdot t) \\ \sin B(\omega \cdot t) & \cos B(\omega \cdot t) \end{smallmatrix}\right) z$ brings Eqs. (3.7_ω) to the form

$$z' = \begin{pmatrix} 0 & -b_0 \\ b_0 & 0 \end{pmatrix} z. \tag{3.8_ω}$$

The hypothesis that $k = 1$ imposes a condition on b_0 relative to the frequency module $\mathcal{M}_\Omega$ of $(\Omega, \mathbb{R})$, namely that there does not exist a rational number r such that $r b_0 \in \mathcal{M}_\Omega$. When this condition holds, the flow $(\Sigma, \mathbb{R})$ defined by Eqs. (3.8_ω) is minimal and almost periodic. If $(\Omega, \mathbb{R})$ is quasi-periodic, then $(\Sigma, \mathbb{R})$ is a Kronecker-type minimal flow.

If the second possibility is realized one has a less simple situation, which however can be understood thanks to [55]. First of all, it turns out that $(\Sigma, \mathbb{R})$ is minimal but not almost periodic. Further information can be obtained by distinguishing two subcases, as follows. For simplicity, set $b_0 = 0$.

(1) Suppose that there exists a ν-measurable but noncontinuous function $B : \Omega \to \mathbb{R}$ such that $B(\omega \cdot t) - B(\omega) = \int_0^t b(\omega \cdot s) \, \mathrm{d}s$ for all $t \in \mathbb{R}$, $\omega \in \Omega$. We saw earlier that the class $\mathcal{C}_1$ of functions $b \in C_0(\Omega)$ which have this property is dense in $C_0(\Omega)$. Let $\theta \in \mathbb{R}$ be an angular coordinate mod π on $\mathbb{P}$. For each fixed value $\theta \in [0, \pi)$, set $\theta_\omega = (\theta + B(\omega)) \mathrm{mod}\, \pi$, then

note that the set $\{(\omega,\theta_\omega) \mid \omega \in \Omega\}$ is a measurable invariant section of Σ. There is an ergodic measure μ_θ on Σ defined as follows:

$$\int_\Sigma h\,\mathrm{d}\mu_\theta = \int_\Omega h(\omega,\theta_\omega)\,\mathrm{d}\nu(\omega) \quad \bigl(h \in C(\Sigma)\bigr).$$

That is, the flow $(\Sigma,\mathbb{R})$ laminates into measurable invariant sections which define ergodic measures μ_θ on Σ. A similar situation was considered when $k = 2$.

(2) There exists no measurable function B with the above property. As we saw before, the class $\mathcal{C}_2 \subset C_0(\Omega)$ of such functions b is residual in $C_0(\Omega)$. When $b \in \mathcal{C}_2$, the flow $(\Sigma,\mathbb{R})$ admits a unique ergodic measure μ (see [55], Lemma 2.1). It can be verified that μ is equivalent to the product of ν with the normalized Lebesgue measure m on $\mathbb{P}$.

Before considering the situations envisioned in subsections (B) and (C), we state a lemma which gives some a priori information concerning the structure of the projective flow in these cases.

LEMMA 3.9. *Let* $(\Omega,\mathbb{R})$ *be an almost periodic minimal flow, let* $A:\Omega \to \mathrm{sl}(2,\mathbb{R})$ *be a continuous function, and let* $(\Sigma,\mathbb{R})$ *be the projective flow defined by Eqs.* (3.1_ω). *Suppose that* Σ *contains exactly one minimal set* M, *and that some Eq.* (3.1_ω) *admits an unbounded solution.*

Then either M *is a proximal extension of* Ω, *or* M *is a proximal extension of an almost periodic two-cover of* Ω. *In the latter situation,* M *is an almost automorphic extension of an almost periodic two-cover of* Ω.

See Definitions 3.5 for the meaning of the term “proximal extension”. A proof of Lemma 3.9 is given in ([83], Section 7). We only sketch it here.

To begin, suppose that $(M,\mathbb{R})$ is not a proximal extension of $(\Omega,\mathbb{R})$. Then there is a point $\bar\omega \in \Omega$ together with a distal pair $\bar m_1 = (\bar\omega,\bar l_1), \bar m_2 = (\bar\omega,\bar l_2)$ of points in M. Letting d be a metric on $\mathbb{P}$, and writing $\hat\tau_t(\bar\omega,\bar l_i) = (\tau_t(\bar\omega), l_i(t))$ $(i = 1,2)$, we can find a number $\delta > 0$ such that $d(l_1(t),l_2(t)) \geqslant \delta$ for all $t \in \mathbb{R}$. Passing to the closure of one of the orbits $\{\hat\tau_t(\bar m_i) \mid t \in \mathbb{R}\}$ and using the minimality of M, one shows that, for each $\omega \in \Omega$, the fiber $\pi^{-1}(\omega) \cap M$ contains a distal pair (m_1,m_2). In particular, each fiber $\pi^{-1}(\omega)$ contains at least two points.

Using Lemma 3.1 together with by-now familiar reasoning using matrix solutions of Eqs. (3.1_ω), one can show that there is a residual subset $\Omega_* \subset \Omega$ such that, if $\omega \in \Omega_*$, then $\pi^{-1}(\omega) \cap M$ contains exactly two points. At this point we introduce the proximal relation $\mathcal{P} = \{(m_1,m_2) \in M \times M \mid (m_1,m_2)$ is a proximal pair$\}$. It is clear that $\mathcal{P}$ is invariant in the sense that, if $(m_1,m_2) \in \mathcal{P}$, then $(\hat\tau_t(m_1,m_2)) \in \mathcal{P}$ for all $t \in \mathbb{R}$. It is also clear that, if $(m_1,m_2) \in \mathcal{P}$, then $\pi(m_1) = \pi(m_2)$. Now, it can be shown that $\mathcal{P}$ is a *closed* subset of $M \times M$. According to a general result of Ellis ([40], Lemma 5.17), this implies that $\mathcal{P}$ is an equivalence relation on M. Define Ω_2 to be the topological quotient $M/\mathcal{P}$. One checks that Ω_2 is a compact metrizable space, that it inherits a flow $\{\hat\tau_t^2\}$ from $\{\hat\tau_t\}$, and that $(\Omega_2,\{\hat\tau_t^2\})$ is an almost periodic 2-cover of Ω. One also checks that M is a proximal extension of Ω.

The statement of Lemma 3.9 follows from these considerations. Let us now turn to a discussion of the weakly elliptic case.

(B) Weakly elliptic case

Let $(\Omega, \mathbb{R})$ be an almost periodic minimal flow, and let $A \to \mathrm{sl}(2, \mathbb{R})$ be a continuous function. We impose the following conditions on Eqs. (3.1_ω):

(i) one Eq. (3.1_ω) admits an unbounded solution, hence all Eqs. (3.1_ω) have this property;

(ii) the Lyapunov exponent β of the family (3.1_ω) is zero.

Here the Lyapunov exponent is that with respect to the ergodic measure ν on Ω; see Section 2. The condition (ii) implies that $\frac{1}{t}\ln|\Phi_\omega(t)x_0|$ tends to zero uniformly in $\omega \in \Omega$ and $x_0 \in \mathbb{R}^2$ with $|x_0| = 1$ as $|t| \to \infty$; see Proposition 2.5.

We mention two types of minimal subset $M \subset \Sigma$ which are encountered when conditions (i) and (ii) hold.

First, there are weakly elliptic families (3.1_ω) for which the projective flow $(\Sigma, \mathbb{R})$ contains a (unique) minimal set M which is a genuine 2-cover of Ω. This is a remarkable phenomenon which has no analogue in the periodic case. The first example illustrating it seems to be in [88]; another is given in [123]. These examples both have the property that $(\Omega, \mathbb{R})$ is of limit periodic type. Apparently no example of quasi-periodic type has been constructed. It would be interesting to have a larger body of examples of families (3.1_ω) for which $(\Sigma, \mathbb{R})$ exhibits such a minimal set.

Second, there exist weakly elliptic families (3.1_ω) such that the projective flow $(\Sigma, \mathbb{R})$ is minimal and admits a unique invariant measure. According to Lemma 3.9 and its proof, the minimality of $(\Sigma, \mathbb{R})$ implies that it is a proximal extension of $(\Omega, \mathbb{R})$. Examples of this type were constructed in a more general context by Glasner and Weiss [61]; they used ideas of Fathi and Herman [51] and Anosov and Katok [7]. Subsequently Nerurkar and Sussmann [114,115] have developed very general methods which permit in particular to obtain examples of the present type for various particular classes of coefficients matrices $A(\cdot)$. They can treat the case – very special from their point of view – when $A(\cdot)$ has the form $\begin{pmatrix} 0 & 1 \\ q(\omega) & 0 \end{pmatrix}$, which corresponds to Eqs. (3.1_ω) of Hill–Schrödinger type; they can find functions $q(\cdot)$ for which the family (3.1_ω) gives rise to a minimal, uniquely ergodic projective flow Σ which is a proximal extension of Ω. It seems possible that such projective flows arise “frequently” even in suitable parameterized families of quasi-periodic equations of Schrödinger type with analytic potential q and Diophantine frequency vector; see, e.g., Eliasson [38,39], Puig [134,133].

We do not know of examples of weakly elliptic families (3.1_ω) whose projective flows have properties qualitatively different from those illustrated above. In this regard, it would be interesting to know if there is a weakly elliptic family for which the minimal set $M \subset \Sigma$ is an almost automorphic, non-almost periodic extension of an almost periodic 2-cover Ω_2 of Ω. It would also be satisfying to decide whether or not there are examples for which M is a proximal non-almost automorphic extension of Ω but $M \neq \Sigma$.

We turn to the

(C) Weakly hyperbolic case

Once again let $(\Omega, \mathbb{R})$ be a minimal almost periodic flow, and let $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ be a continuous function. We impose the following conditions:

(i) the family (3.1_ω) does not admit an exponential dichotomy;

(ii) the Lyapunov exponent β of the family (3.1_ω) is positive: $\beta > 0$.

We say that weakly hyperbolic families (3.1_ω) are of "M-V type", in recognition of the papers of Millionščikov [108] and Vinograd [152]. Those authors constructed the first limit periodic resp. quasi-periodic examples of families (3.1_ω) of weakly hyperbolic type. They did not explicitly study the properties of the projective flows corresponding to their families. That was done later in [78,83] and other papers.

Generally speaking, the projective flow $(\Sigma, \mathbb{R})$ of a weakly hyperbolic family (3.1_ω) has remarkable properties. We will amplify this remark in the succeeding discussion. Let us begin by recalling from Section 2 that, in the weakly hyperbolic case, the projective flow $(\Sigma, \mathbb{R})$ admits exactly two ergodic measures μ_1 and μ_2. See Proposition 2.5 and the following discussion. These are supported on the measurable invariant sections of Σ which are defined by the "traces" in Σ of the Oseledets measurable invariant subbundles; see Section 2. Moreover, according to the discussion in the present Section 3, the projective flow $(\Sigma, \mathbb{R})$ contains exactly one minimal set $(M, \mathbb{R})$. It is an exercise to show that the two ergodic measures μ_1, μ_2 are actually supported on M. According to Proposition 3.9, $(M, \mathbb{R})$ is a proximal extension of $(\Omega, \mathbb{R})$.

It seems important to us to discuss the ideas underlying the construction of the examples in [108] and [152]. This is because those ideas, albeit in somewhat amplified form, have been applied by many authors since. So let us consider a fixed Bohr almost periodic function $A : \mathbb{R} \to \mathrm{sl}(2, \mathbb{R})$ together with the corresponding two-dimensional linear system

$$x' = A(t)x. \tag{3.9}$$

If x_1, x_2 are nonzero vectors in $\mathbb{R}^2$, let $\Theta(x_1, x_2)$ denote the counterclockwise angle between x_1 and x_2. Suppose that there exist a number $\delta > 0$, sequences $s_k \to -\infty$ and $t_k \to \infty$, and solutions $x_1^{(k)}(t), x_2^{(k)}(t)$ of (4.71) such that the following conditions hold:

$$\begin{aligned}
&\bigl|x_1^{(k)}(0)\bigr| = 1 \quad \text{and} \quad \frac{1}{t_k}\ln\bigl|x_1^{(k)}(t_k)\bigr| \leqslant -\delta;\\
&\bigl|x_2^{(k)}(0)\bigr| = 1 \quad \text{and} \quad \frac{1}{s_k}\ln\bigl|x_2^{(k)}(s_k)\bigr| \geqslant \delta;\\
&\Theta\bigl(x_1^{(k)}(0), x_2^{(k)}(0)\bigr) < \frac{1}{k}.
\end{aligned} \tag{$*$}$$

Let us note that Proposition 2.5 together with either of the first two conditions in $(*)$ imply that the family (3.1_ω) obtained from (3.9) via the Bebutov construction can be neither elliptic nor weakly elliptic. There remain just two possibilities: either the family (3.1_ω) has an exponential dichotomy, or it is weakly hyperbolic. Suppose for contradiction that it has an exponential dichotomy. Then it can be verified that Eqs. (4.71) admit solutions $x_1(t), x_2(t)$, with $|x_1(0)| = |x_2(0)| = 1$, such that the following conditions are valid:

$$\lim_{|t|\to\infty} \frac{1}{t}\ln\bigl|x_1(t)\bigr| \leqslant -\delta, \qquad \lim_{|t|\to\infty} \frac{1}{t}\ln\bigl|x_2(t)\bigr| \geqslant \delta. \tag{$**$}$$

We can write $x_i^{(k)}(0) = (\cos\theta_i^{(k)}, \sin\theta_i^{(k)})$ and $x_i(0) = (\cos\theta_i, \sin\theta_i)$ $(i = 1, 2)$. Passing to subsequences, we can assume that $\theta_i^{(k)} \to \bar{\theta}_i \in \mathbb{R}$ $(i = 1, 2)$. Let us show that $\bar{\theta}_1 =$

$\theta_1 \bmod \pi$. Suppose this is not true. Let $\Psi_k(t)$ be the fundamental matrix solution of (3.9) whose columns are $x_1^{(k)}(t)$ and $x_1(t)$. Then $|\sin(\theta_1^{(k)} - \theta_1)| = |\det \Psi_k(0)| = |\det \Psi_k(t)|$ is bounded away from zero for all sufficiently large k. However $\lim_{k\to\infty} \det \Psi_k(t_k) = 0$ by $(*)$ and $(**)$, so one has a contradiction.

In a similar way, one shows that $\bar{\theta}_2 = \theta_2 \bmod \pi$ (use the existence of the sequence (s_k)). Now, however, $\theta_2 = \theta_1 \bmod \pi$, because of the relation in the third line of $(*)$. We conclude that Eq. (3.9) gives rise to a family which is weakly hyperbolic.

Two points should be made concerning the above construction. First of all, Millionščikov's example [108] satisfies the condition $(*)$. Also, Vinograd's example [152] satisfies a variant of $(*)$ wherein one must translate the origin from $t = 0$ and make use of the stronger relations which substitute for $(**)$

$$\limsup_{|t-s|\to\infty} \frac{1}{t-s} \ln \frac{|x_1(t)|}{|x_1(s)|} \leqslant -\delta,$$

$$\liminf_{|t-s|\to\infty} \frac{1}{t-s} \ln \frac{|x_2(t)|}{|x_2(s)|} \geqslant \delta.$$

Second, conditions $(*)$ give a concrete meaning to the intuitive hypothesis that "the Oseledets bundles of the family (3.1_ω) are not bounded apart". This intuitive hypothesis has been rendered explicit and applied by later authors in ways similar to conditions $(*)$; see, e.g., [19,118].

Still another point to be made is that, for discrete two-dimensional system, a subharmonic trick due to Herman [68] allows one to construct discrete weakly hyperbolic cocycles with values in $\mathrm{SL}(2,\mathbb{R})$. Herman's method and generalizations thereof have been fruitfully applied in the study of the discrete Schrödinger operator, as evidenced by a large literature which we do not attempt to review.

We now show that examples of M-V type illustrate various interesting phenomena related to the behavior of solutions of linear, two-dimensional differential systems.

We first consider a problem posed by Marcus and Moore [107] concerning disconjugate solutions of the almost periodic Hill–Schrödinger equation. Consider the second-order equation

$$-\varphi'' + q(t)\varphi = E\varphi \tag{3.10}$$

where $q(\cdot)$ is a Bohr almost periodic function, and E is a real parameter. It is well-known that there is a number E_0 such that, if $E \leqslant E_0$, then every nonzero solution of (3.10) admits at most one zero on $[0,\infty)$. That is to say, Eq. (3.10) is disconjugate on $[0,\infty)$. On the other hand, if $E > E_0$, then every nonzero solution of (3.10) has infinitely many zeroes which cluster at $t = \infty$. One says that (3.10) is oscillatory at $t = \infty$. See, e.g., [28,67]. The concept of disconjugacy has connections to the calculus of variations which we do not discuss here.

If Eq. (3.10) is disconjugate, then it turns out that it admits a "smallest", or *principal* solution $\varphi_0(t)$. In the quasi periodic case (and more generally in the case when $q(\cdot)$ is

Birkhoff recurrent), the principal solution is positive on all of $\mathbb{R}$, and is uniquely defined by the following property: if $\varphi_1(t)$ is a solution of (3.10) which is independent of $\varphi_0(t)$, then

$$\frac{\varphi_0(t)}{\varphi_1(t)} \to 0 \quad \text{as } t \to \infty.$$

This condition makes sense because $\varphi_1(t)$ is nonzero for all large t. An equivalent property is the following: φ_0 is, up to a constant multiple, the unique solution of (3.10) which satisfies

$$\int^{\infty} \frac{\mathrm{d}t}{\varphi_0(t)^2} = \infty.$$

Marcus and Moore posed the following problem. Let $\varphi_0(t)$ be the principal solution of Eq. (3.10); is it the case that the logarithmic derivative $\frac{\mathrm{d}}{\mathrm{d}t} \ln \varphi_0(t)$ is almost periodic? If q is a periodic function, then $\frac{\varphi_0'(t)}{\varphi_0(t)}$ is indeed periodic with the same period as q. Also, if q is almost periodic and $\frac{\varphi_0'(t)}{\varphi_0(t)}$ is almost periodic, then the frequency module of the latter is contained in that of the former [107]. Still another general fact is that, if $E < E_0$, then the Marcus–Moore question has a positive answer. So, in this regard, E_0 is the only problematic value of E.

It turns out that the Marcus–Moore question in general has a negative answer. We proceed to explain in outline how counterexamples can be constructed.

It is convenient to rephrase the Marcus–Moore problem by introducing the Bebutov hull $(\Omega, \mathbb{R})$ of the function q. Let $Q : \Omega \to \mathbb{R}$ be a continuous function and let $\omega_0 \in \Omega$ such that $Q(\omega_0 \cdot t) = q(t)$. We introduce the family of equations

$$-\varphi'' + Q(\omega \cdot t)\varphi = E\varphi \tag{3.10_ω}$$

and the corresponding family of differential systems

$$x' = \begin{pmatrix} 0 & 1 \\ -E + Q(\omega \cdot t) & 0 \end{pmatrix} x, \quad x = \begin{pmatrix} \varphi \\ \varphi' \end{pmatrix} \in \mathbb{R}^2. \tag{3.11_ω}$$

For each $E \in \mathbb{R}$, Eqs. (3.11_ω) determine a projective flow $(\Sigma, \{\tau_t\})$.

We state without proof some general facts; see, e.g., [86] for more discussion. To begin, if $E < E_0$, then Eqs. (3.11_ω) admit an exponential dichotomy. For each $\omega \in \Omega$, let $l_\omega^+ \in \mathbb{P}$ resp. $l_\omega^- \in \mathbb{P}$ be the fiber of the stable resp. unstable bundle. Thus in the notation of Definitions 2.2., l_ω^+ is the image of the projection $P(\omega)$, while l_ω^- is its kernel. If $\Phi_\omega(t)$ is the fundamental matrix solution of Eq. (3.11_ω) and if $x_0 \in l_\omega^\pm$, then $\Phi_\omega(t)x_0 \to 0$ exponentially as $t \to \pm\infty$.

Let θ be a π-periodic angular coordinate on $\mathbb{P}$, so that $\theta = -\pi/2$ and $\theta = \pi/2$ parameterize the φ'-axis in the $\binom{\varphi}{\varphi'}$-space, and other elements $l \in \mathbb{P}$ have parameter values in $(-\pi/2, \pi/2)$. Using the particular way in which Eqs. (3.11_ω) depend on E, one can prove that, if $\omega \in \Omega$ and E is increased from $-\infty$ to E_0 then $l_\omega^+ \equiv l_\omega^+(E)$ moves counterclockwise on $\mathbb{P}$ starting near $\theta = -\pi/2$, while l_ω^- moves clockwise on $\mathbb{P}$ starting from $\theta = \pi/2$. Letting E tend to E_0 from the left, we see that, at $E = E_0$, there are two invariant sections $s^\pm$ of the projective bundle Σ, defined by $s^\pm(\omega) = \lim_{E \to E_0^-} l_\omega^\pm(E)$. These sections are semicontinuous in ω, because they can be expressed as pointwise limits of monotone sequences of continuous functions. See again [86] for a discussion of these facts. Furthermore, it can be shown [92] that, for each $\omega \in \Omega$, the line $s^+(\omega) \in \mathbb{P}$ determines the principal solution of Eqs. (3.10_ω) in the sense that, if $0 \neq \bar{x} = \binom{\bar{\varphi}}{\bar{\varphi}'} \in s^+(\omega)$, then the solution $\varphi_0(t)$ of (3.10_ω) with $\varphi_0(0) = \bar{\varphi}$, $\varphi_0'(0) = \bar{\varphi}'$ is principal; the converse statement also holds.

Let $S_\pm = \operatorname{cls}\{(\omega, s^\pm(\omega)) \mid \omega \in \Omega\} \subset \Sigma$, and let $M_\pm$ be a minimal subset of $S_\pm$. Let us observe that, by the semicontinuity of the sections $s_\pm$, there is a residual subset $\Omega_1 \subset \Omega$ such that, if $\omega \in \Omega_1$, then the fiber $\pi^{-1}(\omega) \cap S_\pm$ contains exactly one point, and hence $\pi^{-1}(\omega) \cap M_\pm$ also contains exactly one point, for each choice of sign $\pm$.

We claim that $M_+ = M_-$. For suppose that this is not true. Then M_+ and M_- are disjoint. Let $f : \Sigma \to \mathbb{R}$ be the function of Eqs. (2.3_ω), Section 2. Then if $\omega \in \Omega$, if $x(t)$ is a solution of (3.11_ω) with $|x_0(0)| = 1$, and if $l \in \mathbb{P}$ contains $x(0)$, then

$$\ln\bigl|x(t)\bigr| = \int_0^t f\bigl(\hat{\tau}_s(\omega, l)\bigr)\,\mathrm{d}s.$$

Let $m_1 \in M_+$ and let $\pi(m_1) = \omega \in \Omega$. Suppose that $\int_0^t f(\hat{\tau}_s(m_1))\,\mathrm{d}s$ is bounded (above and below) for all $t \in \mathbb{R}$. Using a familiar argument involving a matrix solution of Eq. (3.11_ω) (see the proofs of Proposition 2.5 and Proposition 3.3), one shows that, if $m_2 \in M_-$ and $\pi(m_2) = \omega$, then $\int_0^t f(\hat{\tau}_s(m_2))\,\mathrm{d}s$ is also bounded. This implies that all solutions of (3.11_ω) are bounded. But it is then an exercise to show that Eq. (3.10_ω) cannot have a principal solution. We conclude that $\int_0^t f(\hat{\tau}_s(m_1))\,\mathrm{d}s$ is unbounded for some (hence all) $m_1 \in M_+$. The same unboundedness holds for all $m_2 \in M_-$. Now however, using the oscillation Lemma 3.1, we can determine a residual subset $\tilde{\Omega}$ of Ω such that, if $\omega \in \tilde{\Omega}$, then Eq. ($3.10_\omega$) has no principal solution. So we must conclude that $M_+ = M_-$.

Let us write M for the common value of M_+ and M_-. Some additional reasoning shows that: (i) $(M, \mathbb{R})$ is an almost automorphic extension of $(\Omega, \mathbb{R})$ with projection equal to $\pi : M \to \Omega$; (ii) the Marcus–Moore question has an affirmative answer if and only if the projection π defines a flow isomorphism of $(M, \mathbb{R})$ onto $(\Omega, \mathbb{R})$. Furthermore, (iii) if π is a flow isomorphism, then the Lyapunov exponent of the family (3.11_ω) is zero. See [86].

Now however, one can construct families (3.10_ω) for which the corresponding families (3.11_ω) are of M-V type. One such family was determined in [86], using a rotation method of the sort applied by Millionščikov. Later other examples were found, in which $(\Omega, \mathbb{R})$ is quasi-periodic with Diophantine frequency vector and $Q : \Omega \to \mathbb{R}$ is real analytic (e.g., [14]). For families (3.11_ω) of M-V type, the minimal set $M \subset \Sigma$ must be an almost automorphic extension of Ω which is not almost periodic. The Marcus–Moore question has a negative answer for each Eq. (3.10_ω) if the family (3.11_ω) is of M-V type; this follows from the positivity of the Lyapunov exponent β for families of M-V type.

If Eqs. (3.11_ω) are of M-V type, then the principal solutions of the corresponding Eqs. (3.10_ω) exhibit quite remarkable behavior. We justify this remark. First, a variant of Lemma 3.1 allows one to find a residual subset $M_0 \subset M$ such that, if $m_0 \in M_0$, then

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t f\big(\hat{\tau}_s(m_0)\big)\,\mathrm{d}s = \beta, \qquad \liminf_{t\to\infty} \frac{1}{t}\int_0^t f\big(\hat{\tau}_s(m_0)\big)\,\mathrm{d}s = -\beta.$$

Let $\Omega_0 = \pi(M_0)$; one checks that Ω_0 is residual in Ω. On the other hand, there is a residual subset $\Omega_1 \subset \Omega$ such that, if $\omega \in \Omega_1$, then $\pi^{-1}(\omega) \cap M$ contains exactly one point (ω, l). If $0 \neq \bar{x} \in l$ and $\bar{x} = \binom{\bar{\varphi}}{\bar{\varphi}'}$, then the solution $\varphi_0(t)$ of (3.10_ω) satisfying $\varphi_0(0) = \bar{\varphi}$ and $\varphi_0'(0) = \bar{\varphi}'$ is a principal solution. Now $\Omega_* = \Omega_0 \cap \Omega_1$ is a residual subset of Ω. If $\omega \in \Omega_*$, then the principal solution $\varphi_0(t)$ exhibits both exponential growth and decay as $t \to \infty$, in the sense that $\limsup_{t\to\infty} \frac{1}{t} \ln \varphi_0(t) = \beta$ and $\liminf_{t\to\infty} \frac{1}{t} \ln \varphi_0(t) = -\beta$. This is surely a curious phenomenon.

As another consequence of the M-V property, we see that the principal solution of (3.10_ω) is not a continuous function of ω. In fact, in a family (3.11_ω) of M-V type, the section $s_+(\cdot)$ cannot be continuous because if they were, the projection $\pi : (M, \mathbb{R}) \to (\Omega, \mathbb{R})$ would be a flow isomorphism. Thus the lines $l_+(\omega) \in \mathbb{P}$ defining the initial conditions of the principal solutions of Eqs. (3.10_ω) have points of discontinuity; in fact $\omega \mapsto l_+(\omega)$ is only semicontinuous.

A second problem which can be solved by constructing a differential system of M-V type is the following. Return to the family (3.11_ω). The Lyapunov exponent β of this family is a function of the parameter E. It is natural to ask if $\beta = \beta(E)$ is continuous. We are in effect asking if the Lyapunov exponent of the almost periodic Schrödinger equation (3.10_ω) is always continuous as a function of E.

It is easy to see that β is continuous for values of E for which Eqs. (3.11_ω) admit an exponential dichotomy. One can further show that β is continuous at a point $E_* \in \mathbb{R}$ if $\beta(E_*) = 0$. Thus, if β is discontinuous at a point E_*, then the family (3.11_ω) with $E = E_*$ must be of M-V type, i.e., weakly hyperbolic.

There are reasons to think that β might be continuous at all values of E. For, the rotation number α of the family (3.11_ω) does depend continuously on E; this follows from Proposition 2.7 or from a direct argument of Krylov–Bogoliubov type. Moreover, the complex combination $w(E) = -\beta(E) + \mathrm{i}\alpha(E)$ admits a holomorphic extension from the real E-axis to the upper half of the complex E-plane [89]. Thus β and α are conjugate harmonic functions of E for $\Im E > 0$. One might now hope to apply the arguments available to the effect that regularity properties of $\alpha(\cdot)$ imply regularity properties of $\beta(\cdot)$ for real values of the argument E. See, e.g., [62].

It turns out, however, that one can construct an almost periodic function q for which $\beta = \beta(E)$ is discontinuous at the right end-point E_0 of the disconjugacy set $\{E \in \mathbb{R} \mid \text{Eq. } (3.10_\omega) \text{ is disconjugate}\}$. Apparently the first example of this type was given in [80]. The family (3.11_ω) corresponding to $E = E_0$ is of M-V type. By repeating the considerations concerning the stable and unstable bundles which were made in the discussion of the Marcus–Moore problem, we see that the unique minimal subflow $(M, \mathbb{R})$ of the projective flow $(\Sigma, \mathbb{R})$ determined by Eqs. (3.11_ω) is an almost automorphic extension of $(\Omega, \mathbb{R})$.

It seems that few examples are known of almost periodic Schrödinger equations for which the Lyapunov exponent $\beta = \beta(E)$ has discontinuity points. Indeed, there are results concerning the discrete quasi-periodic Schrödinger equation which state, roughly speaking, that if the frequency vector is Diophantine and if the potential is highly regular, then the Lyapunov exponent β depends continuously on the energy parameter E. See, e.g., [23]. Assuming that such results are also valid for the continuous Schrödinger operator (3.10_ω), one is led to formulate questions concerning "minimal conditions" on $(\Omega, \mathbb{R})$ and on Q which imply that β is continuous in E. So far these questions appear to be unanswered.

We close the discussion by noting that there are very general results concerning Lyapunov exponents and so-called dominated splittings which, in the present case, yield discontinuity points $Q_* \in C(\Omega)$ of β when β is thought as a function of $Q \in C(\Omega)$. See [19] for an excellent discussion of this topic. However, it is not clear from these results how one might pick out families of functions $Q = Q(E_1, \dots, E_r)$, depending on finitely many parameters, for which $\beta = \beta(E_1, \dots, E_r)$ admits points of discontinuity.

A third theme which can be elaborated upon in a fruitful way using families (3.1_ω) of M-V type is that of strange nonchaotic attractors or SNAs. In the following lines, we will summarize a part of an excellent article by Jorba, Núñez, Obaya, and Tatjer [99]; the reader is referred to that paper for more information. The main point to be made is that certain families (3.1_ω) with the M-V property give rise to projective flows which contain SNAs.

Following [99], we discuss the concept of SNA. We work for a moment in the category of *discrete* flows: we recall that a discrete flow on a metric space Ω is defined by iterating a fixed homeomorphism $\tau : \Omega \to \Omega$ and its inverse τ^{-1}. Let $\Omega = \mathbb{T}^d$, the d-torus with $d \geqslant 1$. Let $\psi_1, \dots, \psi_d$ be angular coordinates mod 2π on $\mathbb{T}^d$, and let $\gamma_1, \dots, \gamma_d$ be real numbers such that the $d + 1$-tuple $1, \gamma_1, \dots, \gamma_d$ is linearly independent over the rational field $\mathbb{Q}$. Consider the homeomorphism $\tau : \Omega \to \Omega$ defined by

$$\tau(\omega) = (\psi_1 + \gamma_1, \dots, \psi_d + \gamma_d) \quad \text{if } \omega = (\psi_1, \dots, \psi_d) \in \Omega.$$

Of course the angular quantities are taken mod 2π. It is well-known that, for each $\omega \in \Omega$, the orbit $\{\tau^n(\omega) \mid -\infty < n < \infty\}$ is dense in Ω, so one can think of the discrete flow (Ω, τ) as a discrete version of a Kronecker winding on $\Omega = \mathbb{T}^d$.

Now we introduce a continuous map $\hat{\tau} : \Omega \times \mathbb{R} \to \Omega \times \mathbb{R}$ of the following type. Let $\varphi : \Omega \times \mathbb{R} \to \mathbb{R}$ be continuous. Assume that the partial derivative $\frac{\partial \varphi}{\partial x}(\omega, x)$ is well-defined and continuous on $\Omega \times \mathbb{R}$, and that

$$\frac{\partial \varphi}{\partial x}(\omega, x) > 0 \quad \text{for all } (\omega, x) \in \Omega \times \mathbb{R}.$$

Then of course one has the monotonicity condition $\varphi(\omega, x_1) < \varphi(\omega, x_2)$ whenever $\omega \in \Omega$ and $x_1 < x_2$. We set

$$\hat{\tau}(\omega, x) = \bigl(\tau(\omega), \varphi(\omega, x)\bigr).$$

Clearly $\hat{\tau}$ is of skew-product type in the sense that the first coordinate on the right-hand side depends on ω but not on x.

Say that a Lebesgue measurable map $c:\Omega \to \mathbb{R}$ is a τ-invariant curve if it is bounded and $\varphi(\omega, c(\omega)) = c(\tau(\omega))$ for all $\omega \in \Omega$. The corresponding $\hat{\tau}$-invariant graph is $C = \{(\omega, c(\omega)) \mid \omega \in \Omega\} \subset \Omega \times \mathbb{R}$. Let ν be the unique τ-invariant measure on Ω (which coincides with the normalized Lebesgue measure on $\Omega = \mathbb{T}^d$). We can define a $\hat{\tau}$-invariant measure μ_c on $\Omega \times \mathbb{R}$ by the formula

$$\int_{\Omega\times\mathbb{R}} h(\omega, x)\, \mathrm{d}\mu_c(\omega, x) = \int_\Omega h\bigl(\omega, c(\omega)\bigr)\, \mathrm{d}\nu(\omega)$$

for each continuous function $h : \Omega \times \mathbb{R} \to \mathbb{R}$.

We introduce the *Lyapunov exponent* β_s of c, given by

$$\beta_s(c) = \int_\Omega \ln \frac{\partial\varphi}{\partial x}\bigl(\omega, c(\omega)\bigr)\, \mathrm{d}\nu(\omega) = \int_{\Omega\times\mathbb{R}} \left(\ln \frac{\partial\varphi}{\partial x}\right) \mathrm{d}\mu_c.$$

If the Lyapunov exponent $\beta_s(c)$ is negative, it measures the "vertical" contraction along the fiber $\mathbb{R}$ towards $c(\omega)$, for ν-a.a. $\omega \in \Omega$.

Next we follow T. Jäger [70] and make the following

DEFINITION 3.10. A strange nonchaotic attractor or SNA (in $\Omega \times \mathbb{R}$) is the graph of a noncontinuous, τ-invariant curve c with a negative Lyapunov exponent.

As is pointed out in [99], it is of interest to consider subsets $M \subset \Omega \times \mathbb{R}$ which are nonempty, compact, $\hat{\tau}$-invariant in the sense that $\hat{\tau}(M) \subset M$, and minimal with respect to these properties. Such a set M is called minimal. It turns out that, when restricted to M, $\hat{\tau}$ is invertible (we did not assume that $\hat{\tau}$ is invertible on $\Omega \times \mathbb{R}$), so that $(M, \hat{\tau})$ is a discrete flow. One can show that each orbit $\{\hat{\tau}^n(m) \mid -\infty < n < \infty\}$ is dense in M, and one can further show that $(M, \hat{\tau})$ is an almost automorphic extension of (Ω, τ). That is, if $\pi : \Omega \times \mathbb{R} \to \Omega$ is the projection, then there is a residual subset $\Omega_* \subset \Omega$ such that, if $\omega_* \in \Omega_*$, then $\pi^{-1}(\omega_*) \cap M$ contains exactly one point. Such minimal sets are analyzed in [99] and we refer to that paper for more information.

Whenever there exists a τ-invariant section c as above, the boundedness of the graph C ensures the existence of a minimal set M. Such an M need not contain an SNA. However, it is explained in [99] how a quasi-periodic family of Schrödinger equations with the M-V property at $E = E_0$ determines a minimal set which contains an SNA. We now discuss this matter.

Let us return momentarily to the framework of continuous (real) flows. Let $\Omega_c = \mathbb{T}^{d+1}$ be the $(d + 1)$-torus $(d \geqslant 1)$, and let $(\psi_0, \psi_1, \dots, \psi_d)$ be angular coordinates mod 2π on Ω_c. Let $\gamma_1, \dots, \gamma_d$ be real numbers such that $1, \gamma_1, \dots, \gamma_d$ are linearly independent over the rational field $\mathbb{Q}$. If $\omega_c = (\psi_0, \psi_1, \dots, \psi_d)$ mod 2π, set $\tau_t(\omega_c) = (\psi_0 + t, \psi_1 + \gamma_1 t, \dots, \psi_d + \gamma_d t)$ mod 2π. Let $Q : \Omega_c \to \mathbb{R}$ be a continuous function such that Eqs. (10_{ω_c}) have the M-V property at $E = E_0$. Let $(\Sigma, \{\hat{\tau}_t\})$ be the projective flow defined by Eqs. (10_{ω_c}).

Next let θ be the polar angle in $\mathbb{R}^2$, which we regard as a π-periodic angular coordinate on $\mathbb{P}$. It follows from the description given earlier of the projective flow that $(\Sigma, \mathbb{R})$

contains a unique minimal subflow $(M_c, \mathbb{R})$, which is an almost automorphic extension of $(\Omega_c, \mathbb{R})$. Moreover, if $(\omega, l) \in M_c$ and θ parameterizes l, then

$$-\pi/2 < \theta < \pi/2$$

for an appropriate branch of θ.

Next, consider the differential equation (4_{ω_c}) for θ of Section 2. We have

$$\theta' = g\big(\hat{\tau}_t(\omega_c, \theta)\big). \tag{3.12}$$

Let $(\omega_c, \bar{\theta}) \in \Omega_c \times \mathbb{R}$. Let $\theta(t) = \bar{\theta} + \int_0^t g(\hat{\tau}_s(\omega_c, \bar{\theta}))\, \mathrm{d}s$ be the solution of (3.12) satisfying $\theta(0) = \bar{\theta}$. We abuse notation and write $\hat{\tau}_t(\omega_c, \bar{\theta}) = (\tau_t(\omega_0), \theta(t))$. Then $\{\hat{\tau}_t\}$ defines a real flow on $\Omega \times \mathbb{R}$. If values of θ are identified mod π, then $\{\hat{\tau}_t\}$ becomes a flow on Σ defined by Eqs. (3.10_{ω_c}). We identify M_c in the natural way with a subset of $\Omega_c \times (-\pi/2, \pi/2)$; we call this subset M_c, as well.

Let us identify the d-torus $\Omega = \mathbb{T}^d$ with $\{\omega_c = (0, \omega) \mid \omega = (\psi_1, \ldots, \psi_d) \bmod 2\pi\} \subset \Omega_c$. Thus Ω is the section $\psi_0 = 0$ of Ω_c. We define $\tau : \Omega \to \Omega$: $\tau(\omega) = \tau_1(0, \omega)$, where τ_1 is the time-1 map of $\{\tau_t\}$. Then (Ω, τ) is a minimal discrete flow. We also define $\hat{\tau} : \Omega \times \mathbb{R} \to \Omega \times \mathbb{R}$ by $\hat{\tau}(\omega, \bar{\theta}) = \hat{\tau}_1(\omega, \bar{\theta})$. Let

$$M = M_c \cap \big\{(0, \omega, \bar{\theta}) \mid \omega \in \Omega, -\pi/2 < \bar{\theta} < \pi/2\big\}.$$

Then M is invariant with respect to $\hat{\tau}$, and it can be checked that $(M, \hat{\tau})$ is a minimal almost automorphic extension of (Ω, τ).

Now we return to the measurable invariant sections $s^\pm = s^\pm(\omega_c)$ of Σ which we encountered in our discussion of the Marcus–Moore problem. Let $\theta^\pm(\omega_c) \in (-\pi/2, \pi/2)$ be the corresponding values of the angular variable θ. Let $\beta > 0$ be the Lyapunov exponent of Eqs. (3.10_{ω_c}). Let us write $c^\pm(\omega) = \theta^\pm((0, \omega))$ for $\omega \in \Omega$. It can be shown that $\beta_s(c^\pm) = \mp\beta$. It follows that $C^+ = \{(\omega, c^+(\omega)) \mid \omega \in \Omega\}$ satisfies the condition of Definition 3.10, so C^+ is an SNA contained in M. See [99] for a detailed discussion and for further examples of SNAs obtained from quasiperiodic families (3.10_ω), and from quasiperiodic families of the more general form (3.1_ω) which have the M-V property.

We turn to a fourth issue which can be resolved by the construction of an almost periodic family (3.1_ω) which has the M-V property, namely a certain question concerning the behavior of the projective flow when Eqs. (3.1_ω) have unbounded mean motion. As usual, let $(\Omega, \mathbb{R})$ be an almost periodic minimal flow with unique invariant measure ν, let $A : \Omega \to \mathrm{sl}(2, \mathbb{R})$ be a continuous function, and let $(\Sigma, \{\hat{\tau}_t\})$ be the projective flow of the corresponding family (3.1_ω).

In Section 2 we defined the rotation number α of the family (3.1_ω) with respect to the measure ν. We recall the construction. If $\omega \in \Omega$ and $\bar{l} \in \mathbb{P}$, let $\hat{\tau}_t(\omega, \bar{l}) = (\tau_t(\omega), l(t))$. Introduce the polar angle θ in $\mathbb{R}^2$, and view θ as an angular coordinate mod π on $\mathbb{P}$. Letting $\theta(t)$ be a continuous parametrization of $l(t)$, we have Eq. (2.4_ω) of Section 2:

$$\theta' = g\big(\hat{\tau}_t(\omega, \bar{\theta})\big).$$

The rotation number α is by definition $\alpha = \lim_{t\to\infty}\frac{\theta(t)}{t}$. It turns out that the limit determining α is well-defined in the following sense: if ν is an ergodic measure on Ω, then there is a set $\Omega_1 \subset \Omega$ with $\nu(\Omega_1) = 1$ such that, if $(\omega, \bar{\theta}) \in \Omega_1 \times \mathbb{P}$, then the limit exists and does not depend on $(\omega, \bar{\theta})$. See [79]. In the present case, the flow $(\Omega, \mathbb{R})$ supports just one ergodic measure ν. Then, as noted in Proposition 2.7, the following stronger statement holds:

$$\alpha = \lim_{|t|\to\infty} \frac{1}{t} \int_0^t g\big(\hat{\tau}_s(\sigma)\big)\, \mathrm{d}s$$

where the limit is uniform in $\sigma \in \Sigma$.

It is natural to compare αt and $\int_0^t g(\hat{\tau}_s(\sigma))\, \mathrm{d}s$.

DEFINITION 3.11. Say that Eqs. (3.1_ω) have *bounded mean motion* if, for some $\sigma \in \Sigma$, there holds

$$\sup_{t\in\mathbb{R}} \left| \int_0^t g\big(\hat{\tau}_s(\sigma)\big)\, \mathrm{d}s - \alpha t \right| < \infty. \tag{$*$}$$

We now follow the discussion of Yi ([154]; also [16,71]). Yi works with general nonlinear skew-product flows on a circle bundle over Ω, so our case is special from his point of view. First of all, if Eqs. (3.1_ω) have bounded mean motion in the sense of Definition 3.11, then it turns out that condition $(*)$ holds for all $\sigma \in \Sigma$. See ([154], Proposition 3.1).

Second, if Eqs. (3.1_ω) have bounded mean motion, then one can draw deep conclusions about the structure of a minimal subflow $(M, \mathbb{R})$ of the projective flow $(\Sigma, \mathbb{R})$. We refer to [154] for precise statements and proofs, and only summarize the situation here. Assume for simplicity that $(\Omega, \mathbb{R})$ is quasiperiodic. Let $\mathcal{M}_\Omega$ be the frequency module of $(\Omega, \mathbb{R})$; we can write $\mathcal{M}_\Omega = \{n_1\gamma_1 + \cdots + n_d\gamma_d \mid n_1, \ldots, n_d \in \mathbb{Z}\}$ where $\gamma_1, \ldots, \gamma_d \in \mathbb{R}$ are linearly independent over $\mathbb{Q}$. Let $\mathcal{M}_1 = \{n_0\alpha + n_1\gamma_1 + \cdots + n_d\gamma_d \mid n_0, n_1, \ldots, n_d \in \mathbb{Z}\}$; then $\mathcal{M}_1$ is the frequency module of a quasiperiodic flow $(\Omega_1, \mathbb{R})$. The relation between $(\Omega_1, \mathbb{R})$ and $(\Omega, \mathbb{R})$ can be described in terms of the existence and nature of integral relations between $\alpha, \gamma_1, \ldots, \gamma_d$ [154].

It turns out that $(M, \mathbb{R})$ is an almost periodic minimal flow $(\Omega_*, \mathbb{R})$ which is "intermediate" between $(\Omega_1, \mathbb{R})$ and $(\Omega, \mathbb{R})$. If $n_0\alpha \notin \mathcal{M}_\Omega$ for all integers n_0, then $(\Omega_*, \mathbb{R}) = (\Omega_1, \mathbb{R})$. One thus has a general description of the minimal subsets of Σ when bounded mean motion is present. Yi's theory can be extended to the case of a general almost periodic minimal flow $(\Omega, \mathbb{R})$. One needs to define $\mathcal{M}_*$ to be the smallest subgroup of $\mathbb{R}$ which contains α and $\mathcal{M}_\Omega$.

The case when Eqs. (3.1_ω) have unbounded mean motion is less well-understood. Suppose for example that there does not exist an integer $r \neq 0$ such that $r\alpha \in \mathcal{M}_\Omega$. We say that α is irrationally related to $\mathcal{M}_\Omega$. Suppose in addition that Eqs. (3.1_ω) have unbounded mean motion. It has been asked in the literature if these conditions imply that $(\Sigma, \mathbb{R})$ is minimal.

The point we wish to make is that the answer to this question is no. In fact, as Yi notes, an example of [75] has the following properties: (i) there is no integer r such that $r\alpha \in \mathcal{M}_\Omega$;

(ii) Eqs. (3.1_ω) have the M-V property; (iii) the unique minimal set $M \subset \Sigma$ is an almost automorphic extension of Ω. In particular, $M \neq \Sigma$.

So far, we have seen that almost periodic families (3.1_ω) with the M-V property can be constructed which illustrate Marcus–Moore disconjugacy, a discontinuous Lyapunov exponent, and strange nonchaotic attractors. We have also seen that they may give rise to interesting minimal subsets $M \subset \Sigma$ when the bounded mean motion property is absent. All the minimal sets $M \subset \Sigma$ which have arisen have been almost automorphic extensions of Ω.

We note in passing that an almost automorphic minimal subset M of the projective flow $(\Sigma, \mathbb{R})$ determined by an almost periodic flow $(\Omega, \mathbb{R})$ may have interesting topological properties. For instance, the original Vinograd example [152] gives rise to an almost automorphic minimal set $M \subset \Sigma$ which is connected, locally connected at some points, but not locally connected at all points [84]. See [128] for other examples exhibiting this behavior which are invariant sets for 2-dimensional (nonlinear) differential systems. As another instance, we note that the minimal set M mentioned above in connection with mean motion property has "more" Čech cohomology than Ω in a precise sense, despite the fact that M is an almost automorphic extension of Ω. See [17].

We consider a final issue which can be resolved via the construction of an appropriate almost periodic family (3.1_ω) with the M-V property. The issue is that of the existence of minimal flows which have the property of Li–Yorke chaos, but which do not exhibit such traditional indicators of complicated orbital behavior as weak mixing or positive topological entropy. We refer to [18] for a general discussion of flows which do/do not exhibit Li–Yorke chaos. The concept itself derives from a classical paper by Li and Yorke [103].

Let us begin our discussion with the

DEFINITION 3.12. Let Ω be a metric space with metric d and let $(\Omega, \mathbb{R})$ be a flow. A pair $\{\omega_1, \omega_2\} \subset \Omega$ is a *Li–Yorke pair* if $\sup_{t>0}\{d(\omega_1 \cdot t, \omega_2 \cdot t)\} > 0$ and $\inf_{t>0}\{d(\omega_1 \cdot t, \omega_2 \cdot t)\} = 0$. A set $S \subset \Omega$ is called *scrambled* if each pair $\{\omega_1, \omega_2\} \subset S$ is a Li–Yorke pair. The flow $(\Omega, \mathbb{R})$ is *chaotic* in the *sense of Li and Yorke* if Ω contains an uncountable scrambled set.

Let us now focus on the problem of determining almost periodic families (3.1_ω) for which the projective flow $(\Sigma, \mathbb{R})$ admits a minimal subflow $(M, \mathbb{R})$ which exhibits Li–Yorke chaos. Let us note that such a minimal set cannot be weakly mixing. This is because a weakly mixing flow $(X, \mathbb{R})$ has by definition the property that there is a pair $(x_1, x_2) \in X \times X$ with $x_1 \neq x_2$ such that the set $\{(x_1 \cdot t, x_2 \cdot t) \mid t \in \mathbb{R}\}$ is dense in $X \times X$. If a pair $(m_1, m_2) \in M \times M$ had this property, then the pair $(\omega_1, \omega_2) \in \Omega \times \Omega$ of images $\omega_i = \pi(m_i)$ $(i = 1, 2)$ would have the property that $\{(\omega_1 \cdot t, \omega_2 \cdot t) \mid t \in \mathbb{R}\}$ is dense in $\Omega \times \Omega$. However, no such pair exists.

We now follow the remarkable thesis of Bjerklöv ([13]; see also [14]). Let Ω be the 2-torus $\mathbb{T}^2$ with angular coordinates (ψ_1, ψ_2) mod 1 Let γ be an irrational number, and set $\tau_t(\psi_1, \psi_2) = (\psi_1 + t, \psi_2 + t)$ mod 1. Let $Q : \Omega \to \mathbb{R}$ be a C^3 function which has a unique minimum on $\Omega = \mathbb{T}^2$. Suppose further that Q is quadratic in a neighborhood of the point ω_0 where it assumes its minimum value. Thus, assuming for convenience that Q attains its minimum value at $(\psi_1, \psi_2) = (0, 0)$, it is required that $Q(\psi_1, \psi_2) = B(\psi_1, \psi_2) + \mathrm{O}((\psi_1^2 + \psi_2^2)^{3/2})$ where B is a positive definite bilinear form.

Let us consider the following family of linear differential systems of Schrödinger type:

$$x' = \begin{pmatrix} 0 & 1 \\ -E + \lambda Q\bigl(\tau_t(\omega)\bigr) & 0 \end{pmatrix} x. \tag{3.14$_\omega$}$$

Here λ is a real parameter. Among other results, Bjerklöv shows that it is possible to find a (large) λ to which there correspond a (Diophantine) frequency γ and a (large) number E such that the corresponding family (3.14$_\omega$) is of M-V type, and determines a projective flow $(\Sigma, \mathbb{R})$ which is minimal. Such a minimal projective flow differs essentially those of Glasner–Weiss type which we encountered in the weakly elliptic case, because (3.14$_\omega$) has a positive Lyapunov exponent and hence $(\Sigma, \mathbb{R})$ supports exactly two ergodic measures.

Now, using an old triangularization technique (see [83], Section 5), one can show that there is a residual subset $\Omega_* \subset \Omega$ with the following property: if $\omega \in \Omega_*$, then $\pi^{-1}(\omega)$ is a scrambled subset of Σ. In fact, if $l_1, l_2 \in \pi^{-1}(\omega)$, let $\Theta(l_1, l_2)$ be the counterclockwise angle from l_1 to l_2. Let $\Phi_\omega(t)$ be the fundamental matrix solution of (3.14$_\omega$), and set $l_i(t) = \Phi_\omega(t) l_i$ $(i = 1, 2)$. Then one can show that

$$\inf_{t\in\mathbb{R}} \Theta\bigl(l_1(t), l_2(t)\bigr) = 0 \quad \text{and} \quad \sup_{t\in\mathbb{R}} \Theta\bigl(l_1(t), l_2(t)\bigr) = \pi.$$

Thus these examples have the Li–Yorke property. They have zero topological entropy because of a general result of Bowen [22]. See [17] for details. We note that it turns out that the Glasner–Weiss examples also have the Li–Yorke property; see [17].

We close the section by posing a question concerning the projective flow determined by almost periodic families (3.1$_\omega$) of linear differential systems. Namely, can one determine a family (3.1$_\omega$) for which $(\Sigma, \mathbb{R})$ admits a minimal subset M with the property that, for a residual set of $\omega \in \Omega$, the fiber $\pi^{-1}(\omega) \cap M$ is perfect and nowhere dense in $\mathbb{P}$? That is, does there exist an almost periodic, $\mathrm{SL}(2, \mathbb{R})$-valued "Denjoy cocycle"? According to a private communication of T. Jäger, this cannot happen when Ω is a 2-torus. Can other phase spaces Ω be excluded as well?

4. Algebro-geometric Sturm–Liouville coefficients

This section is devoted to the discussion of an inverse spectral problem for the classical Sturm–Liouville operator. The present discussion has interest for various reasons, which we want briefly to explain. First, we exploit methods from the theory of nonautonomous differential systems in dimension 2, by using techniques from ergodic theory, dynamical systems and other fields as well. It is our opinion that such an approach to the study of the inverse spectral properties of the Sturm–Liouville operator allows us to retrieve more information than is present in other sources. Second, it is well known that certain Sturm–Liouville operators have the property that their isospectral classes are preserved by the solutions of a corresponding nonlinear evolution equation, and indeed by the solution of a whole commuting hierarchy of such equations. A prototypical and extensively studied example of this phenomenon is the following. Let $u_t(x) = u(t,x)$ be the solution of the Korteweg–de Vries (K-dV) equation

$$\frac{\partial u}{\partial t} = 3u\frac{\partial u}{\partial x} - \frac{1}{2}\frac{\partial^3 u}{\partial x^3},$$

with appropriate initial condition $u_0(x) = u(0,x)$; then the spectrum $\Sigma(L_t)$ of the Schrödinger operator

$$L_t = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u_t(x)$$

acting in $L^2(\mathbb{R})$ does not depend on t [56]. This fact permits one to explicitly solve the K-dV equation for an ample class of initial data u_0, as a vast literature testifies. The K-dV equation is one of an infinite family of commuting nonlinear evolution equations whose solutions preserve isospectral classes of the Schrödinger operator.

Another example is furnished by the Camassa–Holm equation

$$4\frac{\partial u}{\partial t} - \frac{\partial^3 u}{\partial x^2 \partial t} - 2u\frac{\partial^3 u}{\partial x^3} - 4\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2} + 24u\frac{\partial u}{\partial x} = 0.$$

In this case, the corresponding operator is of Sturm–Liouville type with a nonconstant density function. Actually more than one operator can be used. Following [11], we choose $-\frac{\mathrm{d}^2}{\mathrm{d}x^2} + 1$; introducing a positive density function y, the relevant spectral problem is

$$-\frac{\mathrm{d}^2\varphi}{\mathrm{d}x^2} + \varphi = \lambda y(x)\varphi. \tag{4.1}$$

It turns out that, if $u_t(x) = u(t,x)$ is an appropriate solution of the Camassa–Holm equation, then there is a t-dependent density $y_t = y_t(x)$ such that the spectrum of (4.1) does not depend on t.

We mention that there are also nonlinear evolution equations which are related to isospectral classes of ordinary differential operators which are not of Sturm–Liouville type. As an example, we mention the (nonfocusing) nonlinear Schrödinger (NLS) equation:

$$-\mathrm{i}\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = 2|u|^2 u,$$

together with the AKNS operator

$$L = J^{-1}\left[\frac{\mathrm{d}}{\mathrm{d}x} - \begin{pmatrix} a & b \\ b & -a \end{pmatrix}\right], \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

acting on $L^2(\mathbb{R}, \mathbb{C}^2)$. Here, a and b are real-valued functions of x. For appropriate solutions $u_t(x) = u(t,x)$ of the NLS equation, there is a transformation $u_t \mapsto (a_t, b_t)$ such that the spectrum of

$$L_t = J^{-1}\left[\frac{\mathrm{d}}{\mathrm{d}x} - \left(\begin{pmatrix} a_t & b_t \\ b_t & -a_t \end{pmatrix}\right)\right]$$

does not depend on t. See [1] and much additional literature for more information.

Roughly speaking, there are two classical methods which are used to study the isospectral classes of an operator of Sturm–Liouville type: the first is that of the "inverse scattering method" (see, for instance [11,132]), the second is that in which methods of the theory of algebraic curves are used [35,118,34,96,95,155].

These facts provide a wonderful demonstration of the interplay between the theory of nonautonomous differential systems, algebraic curves and partial differential equations.

In the last two decades, many papers concerning the inverse spectral theory of the Schrödinger operator have been published (see, among others, [11,35,118,132]). We take inspiration from these works, and extend some of those well-known results to a general one dimensional Sturm–Liouville operator L, namely

$$L(\varphi) = (p\varphi')' - q\varphi = -\lambda y\varphi, \quad ' = \frac{\mathrm{d}}{\mathrm{d}t} \tag{4.2}$$

acting on $L^2(\mathbb{R})$.

Here is a more detailed formulation of the problem we study. Equation (4.2) can be written in system form as

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}' = \begin{pmatrix} 0 & \frac{1}{p(t)} \\ q(t) - \lambda y(t) & 0 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}. \tag{4.3}$$

Here p, q, y are uniformly continuous functions, p, y are strictly positive, and $p \in C^1(\mathbb{R})$ has bounded uniformly continuous derivative. This system has, in the nonautonomous case, a maximal Lyapunov exponent $\beta = \beta(\lambda)$. We assume that:

- (H1) The spectrum $\Sigma(L)$ of (4.2) is a finite union of intervals: $\Sigma(L) = [\lambda_0, \lambda_1] \cup [\lambda_2, \lambda_3] \cup \cdots \cup [\lambda_{2g}, \infty)$, where $-\infty < \lambda_0 < \lambda_1 < \cdots < \lambda_{2g}$;
- (H2) The Lyapunov exponent β vanishes on $\Sigma(L)$: $\beta(\lambda) = 0$ for all $\lambda \in \Sigma(L)$.

As we will see, these mild-looking assumptions are sufficient to permit the reconstruction of p, q, and y in terms of algebro-geometric data. In particular, we will see that $\sqrt{py}$ can be described as the restriction of a meromorphic function defined on a generalized Jacobian of the Riemann surface $\mathcal{R}$ of the algebraic relation

$$w^2 = -\prod_{i=0}^{2g}(\lambda - \lambda_i)$$

to a t-motion we will describe in detail and which is general nonlinear (unless $y/p = const$). Some words concerning the assumptions on the spectrum (H1) and (H2): in general, the spectrum $\Sigma(L)$ of a Sturm–Liouville operator L can have a very variegated structure. It can contain isolated points, bands, Cantor parts, or even more complicated sets. One can say that, since L (at least when $p(t)$ is of class $C^1(\mathbb{R})$) defines a self-adjoint operator on the weighted space $L^2(\mathbb{R}, \sqrt{y})$, the spectrum $\Sigma(L)$ is contained in $\mathbb{R}$, is bounded below by a number λ_0 and the set $\mathbb{R} \setminus \Sigma(L)$ is at most a countable union of disjoint open intervals $(\lambda_{2i-1}, \lambda_{2i})$ ($i \in \mathbb{N}$): $\mathbb{R} \setminus \Sigma(L) = (-\infty, \lambda_0) \bigcup_{i=1}^{\infty} (\lambda_{2i-1}, \lambda_{2i})$. However, it is fairly clear that it can be very difficult to study the properties of the spectrum of a Sturm–Liouville operator, as well as to formulate a consistent setting for an inverse problem to be solved. For this reason it is necessary to give assumptions on the functions p, q, y in order to have spectral structures which are "not too wild": those assumptions are equivalent to requiring that the Green function $G(t, s, \lambda)$ associated to Eq. (4.2) behaves "well" at the endpoints of the spectral gaps. This happens, for instance, in the case when we consider potentials which are called "reflectionless", i.e. potentials for which the nontangential limit $\lim_{\varepsilon \to 0^+} \Re G(t, t, \lambda + i\varepsilon) = 0$ for all $t \in \mathbb{R}$ and for Lebesgue a.a. $\lambda \in \Sigma(L)$. This class of potentials contains periodic potentials [106], ergodic potentials [34], algebro-geometric potentials [35,96,95], Sato–Segal–Wilson potentials [141,85], Eliasson potentials [38] and others as well: of course the potentials we consider here are reflectionless. It is possible to extend the results we will obtain under the Hypotheses (H1) and (H2) to some of the more general classes of potentials listed above, by using certain limit procedures (see [97]): in fact, all such potentials are reflectionless and have a spectrum $\Sigma(L)$ which is a countably infinite union of closed intervals such that the length of the spectral gaps satisfy certain specific assumptions. It is not yet known if all the potentials obtained by the limit procedure in [97] are almost periodic (see [34] for a detailed discussion in the case of the Schrödinger operator).

We follow the approach taken in [31] and [57], where analogous inverse problems were posed and solved for the AKNS operator and for the Verblunsky operator arising in the theory of orthogonal polynomials on the unit circle [148].

The key element we use to study our inverse spectral problem is a "dynamical" definition of the Weyl m-functions $m_\pm(\lambda)$. An ample discussion concerning the Weyl m-functions is present in the following. We will sketch the main results of the Gilbert–Person theory for the Schrödinger operator, which can be easily adapted to our more general Sturm–Liouville operator.

We now give a brief summary of the content of this section. It is divided into four subsections.

In Section 4.1, we review some basic facts concerning the Sturm–Liouville operator. Although these facts are very well known, we will systematically use them, hence it could be helpful for the reader to have a quick guide in order to retrieve the necessary information.

We begin Section 4.2 by describing the ergodic-dynamical setting. We define a family $\mathcal{F}$ of Sturm–Liouville systems (4.3), where the functions p, q, y vary in the hull of a given triple (p_0, q_0, y_0) of continuous functions which satisfies certain assumptions. We will apply the concept of exponential dichotomy, and define the Weyl m-functions in a dynamical way.

In Section 4.3 we consider the projective flow in the Sturm–Liouville setting. In particular, we let Ω be a compact metric space, and $\{\tau_t\}$ be a flow on Ω: the projective flow is built in analogy to that of the preceding sections, as $(\Sigma = \Omega \times \mathbb{P}(\mathbb{C}), \{\hat{\tau}_t\})$. Then we introduce the Floquet exponent, the rotation number, the Lyapunov exponent and we extend Kotani's seminal work on the Schrödinger operator [101]. We use systematically the projective flow. We will draw many important conclusions about the behavior of the Weyl m-functions when λ crosses the real line. Moreover we prove that the spectra of the family of Sturm–Liouville equations $\mathcal{F}$ are invariant, i.e. that for a.e. equation in $\mathcal{F}$, the spectrum equals a fixed closed set with no isolated eigenvalues and coincides with the non-dichotomy set of the family $\mathcal{F}$.

In Section 4.4 we pose and solve the inverse problem. In particular, first we find relations occurring between the potentials p, q, y in terms of the finite poles of a meromorphic function which is directly linked to the Weyl m-functions, then we characterize all the ergodic potentials p, q, y satisfying (H1) and (H2).

4.1. *Basic results on the Sturm–Liouville operator*

This part mainly refers to Atkinson [10], Coddington and Levinson [32] and Weinberger [153]. Consider the following differential equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(p(t)\frac{\mathrm{d}f}{\mathrm{d}t}\right) - q(t)f = -\lambda y(t)f(t), \quad t \in [0, b], \tag{4.4}$$

where p, q and y are real valued functions such that $p(t)$ is positive and of class C^1, $y(t)$ is positive and continuous, and $q(t)$ is continuous, together with the boundary conditions

(4.4a) $f(0)\cos\alpha + p(0)f'(0)\sin\alpha = 0$,

(4.4b) $f(b)\cos\beta + p(b)f'(b)\sin\beta = 0$,

where $\alpha, \beta \in [0, \pi)$.

DEFINITION 4.1. The values of $\lambda \in \mathbb{C}$ such that Eq. (4.4) together with the boundary conditions (4.4a) and (4.4b) has a nontrivial solution are the *eigenvalues*. The corresponding solutions are called *eigenfunctions*.

PROPOSITION 4.2. *Eigenfunctions corresponding to different eigenvalues are orthogonal with respect the weight function y.*

All the eigenvalues are real and positive. The set of eigenvalues is at most countable, and has a unique cluster point at ∞.

Equation (4.4) can be written in the following matrix form

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}' = \begin{pmatrix} 0 & 1/p \\ q - \lambda y & 0 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \tag{4.5}$$

which is equivalent to the system

$$\begin{cases} p u_1' = u_2, \\ u_2' = (q - \lambda y)u_1. \end{cases} \tag{4.6}$$

Let $u(t,\lambda)=\binom{u_1(t,\lambda)}{u_2(t,\lambda)}$ be the solution of (4.5) satisfying some fixed initial condition. As $|\lambda|\to\infty$, both u_1 and u_2 behave as follows:

$$u_1(t,\lambda), u_2(t,\lambda)=\mathcal{O}\bigl\{\mathrm{e}^{c\sqrt{|\lambda|}}\bigr\}, \tag{4.7}$$

where c is a constant.

From Eq. (4.7) we obtain:

- (4.7a) the maps $\lambda\mapsto u_{1,2}(t,\lambda)$ are entire and of order at most $1/2$ for every fixed $t\in(0,b)$;
- (4.7b) $u_{1,2}(t,\lambda)$ are entire functions if $t=b$, hence the map $\lambda\mapsto u_1(b,\lambda)\cos\beta+u_2(b,\lambda)\sin\beta$ is entire; this implies that this function can have only countably many zeros, and of course these zeroes are the eigenvalues;
- (4.7c) $\sum_n\lambda_n^{-1/2-\varepsilon}<\infty$ for each $\varepsilon>0$.

For results concerning the exponential growth of the zeros of an entire function, i.e. to prove (4.7c), see, among others, [149, Section 8.22]. In addition the eigenvalues can cluster only at ∞.

Let us now consider Eq. (4.4) together with the boundary conditions

$$f(0)=f(b)=0. \tag{4.8}$$

Let λ_1 be the smallest eigenvalue of Eq. (4.4) with boundary conditions (4.8), and let χ_1 be the corresponding eigenfunction. Then

$$0\neq\lambda_1=\frac{\int_0^b(p(\chi_1')^2+q\chi_1^2)\,\mathrm{d}t}{\int_0^b y\chi_1^2\,\mathrm{d}t}.$$

It is easy to prove that χ_1 does not vanish in $(0,b)$. Since the eigenfunctions are orthogonal, all the other eigenfunctions *must* change sign in $(0,b)$: even more, if $\lambda<\rho$ are different eigenvalues, χ and ψ are the corresponding eigenfunctions and t_0,t_1 are two consecutive zeroes of χ, then there exists $\bar t\in(t_0,t_1)$ such that $\psi(\bar t)=0$. This implies that

PROPOSITION 4.3. *The kth eigenfunction χ_k of Eq.* (4.4) *together with the boundary conditions* (4.8) *has exactly $k-1$ zeroes in* $(0,b)$.

Starting from Eq. (4.4) (which is considered in the interval $[0,b]$, $b\in\mathbb{R}$), we now retrieve information concerning the solutions of the differential equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(p(t)\frac{\mathrm{d}f}{\mathrm{d}t}\right)-q(t)f=-\lambda y(t)f(t),\quad t\in[0,\infty). \tag{4.9}$$

To this end we introduce the Weyl m-functions for the Sturm–Liouville operator.

Let φ_α and ψ_α two linearly independent solutions of (4.4) satisfying the following initial conditions at 0

- (4.9a) $\varphi_\alpha(0,\lambda)=\sin\alpha$, $\psi_\alpha(0,\lambda)=\cos\alpha$
- (4.9b) $p(0)\varphi_\alpha'(0,\lambda)=-\cos\alpha$, $p(0)\psi_\alpha'(0,\lambda)=\sin\alpha$,

where $0 \leqslant \alpha < \pi$. Note that φ satisfies the condition (4.4a). Any other solution χ of Eq. (4.4) (except for ψ) has the form

$$\chi(t) = \varphi_\alpha(t) + m(\alpha, \lambda)\psi_\alpha(t),$$

where $m(\alpha, \lambda) \in \mathbb{C}$. We omit for the moment the α-dependence of the functions involved. If we require that χ satisfies the boundary condition (4.4b), namely

$$\chi(b)\cos\beta + p(b)\chi'(b)\sin\beta = 0,$$

then m must satisfy

$$m = -\frac{\varphi(b,\lambda)\cot\beta + p(b)\varphi'(b,\lambda)}{\psi(b,\lambda)\cot\beta + p(b)\psi'(b,\lambda)}.$$

Clearly, now we have $m = m(\alpha, \beta, b, \lambda) \in \mathbb{C}$.

From the above observations, all the functions $\varphi, \varphi', \psi, \psi'$ are entire functions in λ, hence m is meromorphic in the variable λ. Let us set $z = \cot\beta$; then for fixed (λ, b) we obtain

$$m = -\frac{Az + B}{Cz + D} \tag{4.10}$$

where z varies on the real line, and A, B, C, D are determined by the expression above. The image of the real line is a circle $C_b(\lambda)$ in the m-plane. Thus χ satisfies the boundary conditions in b if and only if $m \in C_b(\lambda)$.

If we use the notation

$$[f, g](t) = p(t)\big(f(t)\bar{g}(t)' - f(t)'\bar{g}(t)\big), \quad f, g \in C^1(0, b)$$

than the equation of the circle $C_b(\lambda)$ is

$$[\chi, \chi](b) = 0, \tag{4.11}$$

that is

$$C_b(\lambda) = \big\{m \in \mathbb{C} \mid [\chi, \chi](b) = 0\big\}.$$

The center c and the radius r of $C_b(\lambda)$ are

$$c = -\frac{[\varphi, \psi](b)}{[\psi, \psi](b)} \tag{4.12}$$

$$r = \frac{1}{|[\psi, \psi](b)|}, \tag{4.13}$$

The interior of the circle $C_b(\lambda)$ is given by the relation

$$\frac{[\chi,\chi](b)}{[\psi,\psi](b)} < 0.$$

Moreover

$$[\psi,\psi](b) = 2\mathrm{i}\Im\lambda \int_0^b y|\psi|^2\,\mathrm{d}t,$$

and

$$[\chi,\chi](b) - [\chi,\chi](0) = 2\mathrm{i}\Im\lambda \int_0^b y|\chi|^2\,\mathrm{d}t.$$

Since $[\chi,\chi](0) = -2\mathrm{i}\Im m$, the interior of the circle is given by

$$\int_0^b y|\chi|^2\,\mathrm{d}t < \frac{\Im m}{\Im\lambda} \quad (\Im\lambda \neq 0).$$

Points m are on the circle if and only if

$$\int_0^b y|\chi|^2\,\mathrm{d}t = \frac{\Im m}{\Im\lambda} \quad (\Im\lambda \neq 0). \tag{4.14}$$

The radius r is given, if $\Im\lambda \neq 0$, by

$$\frac{1}{r} = 2|\Im\lambda| \int_0^b y|\psi|^2\,\mathrm{d}t.$$

Let $0 < a < b < \infty$. If m is inside or on the circle $C_b(\lambda)$, we have

$$\int_0^a y|\chi|^2\,\mathrm{d}t < \int_0^b y|\chi|^2\,\mathrm{d}t \leqslant \frac{\Im m}{\Im\lambda},$$

so m is inside or on the circle $C_a(\lambda)$ as well. This means that if $a < b$, then $C_a(\lambda)$ contains $C_b(\lambda)$. For fixed λ with $\Im\lambda \neq 0$, the map $b \mapsto r(b) = (2|\Im\lambda| \int_0^b y|\psi|^2\,\mathrm{d}t)^{-1}$ is monotone decreasing, and hence the limit $\lim_{b\to+\infty} r(b) := r_+$ exists. We have two possibilities: either $r_+ = 0$ or $r_+ > 0$. In the first case the circles $C_b(\lambda)$ tend to a point $m_+(\lambda)$, in the second case the $C_b(\lambda)$ tend to a circle $C_+(\lambda)$. In the first case, since $r(b) \to 0$, then $\psi(t) \notin L^2([0,\infty), y)$, hence there exists only one solution (up to a constant multiple) which belongs to $L^2([0,\infty), y)$, and this solution is surely χ. In the other case, we can easily see that $\psi \in L^2([0,\infty), y)$. If $\hat{m}$ is any point of $C_+(\lambda)$ then $\hat{m}$ is inside every $C_b(\lambda)$, for all $b > 0$, so

$$\int_0^b y|\chi|^2\,\mathrm{d}t \leqslant \frac{\Im\hat{m}}{\Im\lambda},$$

and if $b\to\infty$, this proves that every solution $\chi=\varphi+\hat{m}\psi$ is in $L^2([0,\infty),y)$.

REMARK 4.4. The discussion we made above shows that solutions of (4.9) which are in $L^2([0,\infty),y)$ always exist: in the limit circle case, every solution which satisfies the boundary conditions mentioned above is square integrable, while in the limit point case there is (up to a constant multiple) only one solution which is square integrable, if $\Im\lambda\neq 0$, and this solution is $\chi(t)$.

We recall

PROPOSITION 4.5. *Let p,q,y be real valued bounded continuous functions such that $p(t)$ is positive and of class C^1, and $y(t)$ is positive. Then Eq.* (4.4) *together with the boundary conditions* (4.9a) *and* (4.9b) *is in the limit point case at ∞.*

As a consequence of Proposition 4.5, for every fixed λ with $\Im\lambda\neq 0$ there exists only one square integrable solution of (4.9) (up to a constant multiple) which is in $L^2([0,\infty),y)$. It turns out that the limit $\lim_{b\to\infty}C_b(\lambda)$ does not depend on the particular choice of β in the boundary conditions. In particular, if we put $\beta=0$ we obtain

$$m_+(\alpha,\lambda)=-\lim_{b\to\infty}\frac{\varphi_\alpha(b,\lambda)}{\psi_\alpha(b,\lambda)}.$$

REMARK 4.6. From now on, unless explicitly stated otherwise, we only consider $\alpha=\frac{\pi}{2}$ and set $m_+(\lambda)=m_+(\pi/2,\lambda)$, to obtain the particularly important relation

$$m_+(\lambda)=\frac{p(0)\chi'(0)}{\chi(0)}, \tag{4.15}$$

where $\chi(t)$ is the only solution of (4.9) which is in $L^2([0,\infty),y)$.

One can retrieve $m_+(\alpha,\lambda)$ from $m_+(\lambda)$ and vice-versa, by using the following simple formulas:

$$m_+(\lambda)=-\frac{\cos\alpha-m_+(\alpha,\lambda)\sin\alpha}{\sin\alpha+m_+(\alpha,\lambda)\cos\alpha},$$

$$m_+(\alpha,\lambda)=\frac{\cos\alpha+m_+(\lambda)\sin\alpha}{\sin\alpha-m_+(\lambda)\cos\alpha}.$$

The function $m_+(\lambda)$ is the *Weyl m-function* at $+\infty$. As is easily seen, an analogous construction can be made for the problem in the negative half-line, giving a Weyl m-function at $-\infty$. We will denote this function with $m_-(\lambda)$. Let $\varphi_+(t,\lambda)$ and $\varphi_-(t,\lambda)$ be the (essentially unique) solutions of (4.9) which are square integrable on the positive and negative half lines respectively (obviously with respect to the weighted measure $y\,\mathrm{d}t$). From (4.15) we have the following important formulas

$$m_+(\lambda) = \frac{p(0)\varphi'_+(0,\lambda)}{\varphi_+(0,\lambda)}, \qquad m_-(\lambda) = \frac{p(0)\varphi'_-(0,\lambda)}{\varphi_-(0,\lambda)}. \tag{4.16}$$

We have

PROPOSITION 4.7. *If* $\Im(\lambda) \neq 0$, $m_\pm$ *are analytic functions of* λ. *In addition,* $\operatorname{Sgn}(\Im m_\pm \Im\lambda) = \pm 1$. *If* $m_\pm$ *have zeroes or poles, they are all real and simple.*

Consider the operator

$$L(\varphi) = \frac{1}{y}\left[\frac{\mathrm{d}}{\mathrm{d}t}\left(p\frac{\mathrm{d}}{\mathrm{d}t}\varphi\right) - q\varphi\right]. \tag{4.17}$$

We will denote by L the self-adjoint closure of operator (4.17) on $L^2(\mathbb{R}, y)$ and with $L^\pm$ the closures of (4.17) on $L^2([0,\infty), y)$ and $L^2((-\infty,0], y)$ respectively.

Consider Eq. (4.4) in the interval $[0,b]$, together with the boundary conditions

$$u(0) = 0, \qquad p(b)u'(b) = 1.$$

Let $(\lambda_{b_n}) \subset \mathbb{R}$ be the sequence of eigenvalues of Eq. (4.4), and let (u_{b_n}) be the corresponding sequence of eigenfunctions. If ψ is the solution of (4.4) which satisfies the second half of the conditions (4.9a) and (4.9b), then ψ satisfies $\psi(0) = 0$, hence we must have $u_{b_n}(t) = r_{b_n}\psi(t,\lambda_{b_n})$, where $r_{b_n} \in \mathbb{C}$.

Let $\rho_b : \mathbb{R} \to \mathbb{R}$ be the monotone nondecreasing step function having jumps of $|r_{b_n}|^2$ at each eigenvalue λ_{b_n}. We take ρ_b to be right-continuous, and $\rho_b(0) = 0$. The function ρ defines a measure, that we still denote by ρ_b, called the spectral measure for Eq. (4.4) in the interval $(0,b)$. If σ is a measure of Lebesgue–Stieltjes type on $\mathbb{R}$, let $L^2(\mathbb{R},\sigma)$ be the set of all the functions $h(\lambda)$ which are σ-measurable and such that

$$\int_{-\infty}^{\infty} \left|h(\lambda)\right|^2 \mathrm{d}\sigma(\lambda) < \infty.$$

We have the following important

THEOREM 4.8.

(i) *There is a monotone nondecreasing function* $\rho(\lambda)$ *defined on the real line, such that*

$$\rho(\lambda) - \rho(\mu) = \lim_{b\to\infty}\bigl(\rho_b(\lambda) - \rho_b(\mu)\bigr),$$

at every point of continuity λ, μ *of* ρ.

(ii) *If* $f \in L^2(0,\infty)$*, there exists a function* $g(\lambda) \in L^2(\mathbb{R},\rho)$ *such that*

$$\lim_{b\to\infty} \int_{-\infty}^{\infty} \left| g(\lambda) - \int_0^b f(t)y(t)\psi(t,\lambda)\,\mathrm{d}t \right|^2 \mathrm{d}\rho(\lambda) = 0$$

and

$$\int_0^\infty y(t)\left|f(t)\right|^2 \mathrm{d}t = \int_{-\infty}^{\infty} \left|g(\lambda)\right|^2 \mathrm{d}\rho(\lambda).$$

(iii) *The map*

$$t \mapsto \int_{-\infty}^{\infty} g(\lambda)\psi(t,\lambda)\,\mathrm{d}\rho(\lambda)$$

converges in $L^2(0,\infty)$ *to* fy.

(iv) *If* $m_+(\lambda)$ *is the Weyl function at* ∞*, then*

$$\frac{\rho(\mu+0^+)-\rho(\mu+0^-)}{2} - \frac{\rho(\lambda+0^+)-\rho(\lambda+0^-)}{2} + \int_\lambda^\mu \mathrm{d}\rho$$
$$= \lim_{\varepsilon\to 0^+} \frac{1}{\pi} \int_\mu^\lambda \Im m_+(\nu + \mathrm{i}\varepsilon)\,\mathrm{d}\nu.$$

(v) *If* $\Im\lambda_0, \Im\lambda_1 \neq 0$*, then*

$$m_+(\lambda_0) - m_+(\lambda_1) = \int_{-\infty}^{\infty} \left(\frac{1}{\lambda-\lambda_0} - \frac{1}{\lambda-\lambda_1} \right) \mathrm{d}\rho(\lambda).$$

Analogous relations hold for the operator L^- *and the Weyl* m*-function* m_- *at* $-\infty$.

The above theorem can be extended to Sturm–Liouville operators on the whole line. As before, we start from the problem in an interval $I = [a,b]$ with $a < 0 < b$, and the boundary conditions

$$\cos\alpha u(a) + \sin\alpha p(a)u'(a) = 0, \tag{4.18}$$

$$\cos\beta u(b) + \sin\beta p(b)u'(b) = 0. \tag{4.19}$$

There is a matrix $P_I = (\rho_{jk})$ (called the *spectral matrix*) associated with Eq. (4.4) in the interval I. Its entries are nondecreasing step functions satisfying

$$\rho_{jk}(\lambda_n+) - \rho_{jk}(\lambda_n-) = r_j \bar{r}_k,$$

and otherwise constant. If we require that $P_I(\lambda+) = P_I(\lambda)$ then P_I is Hermitian, and, if $\lambda > \mu$, $P_I(\lambda) - P_I(\mu)$ is positive semidefinite. If we let $I \to \mathbb{R}$, then $P_I(\lambda) \to P(\lambda)$, where $P(\lambda)$ is a hermitian, positive semidefinite matrix.

REMARK 4.9. Since the matrix $P(\lambda)$ is Hermitian and nondecreasing, if follows that, for every interval $I = [\lambda, \mu]$,

$$\left|\rho_{jk}(\mu) - \rho_{jk}(\lambda)\right|^2 \leqslant \left(\rho_{jj}(\mu) - \rho_{jj}(\lambda)\right)\left(\rho_{kk}(\mu) - \rho_{kk}(\lambda)\right).$$

From this we conclude that the points of nonconstancy of the spectral matrix $P(\lambda)$ are the same of the points of nonconstancy of the trace $\mathrm{Tr}(P(\lambda))$.

We use the notation $\Sigma(L)$, $R(L)$ for the spectrum and the resolvent set of the full-line operator L and $\Sigma^{\pm}(L)$, $R^{\pm}(L)$ for the spectrum and the resolvent set of the positive and negative Sturm–Liouville operators $L^{\pm}$ respectively.

REMARK 4.10. The sets $\Sigma(L)$, $\Sigma^{\pm}(L)$ are closed subsets of $\mathbb{R}$. The set of the points of growth of the spectral matrix $P(\lambda)$ (i.e., of the trace $\mathrm{Tr}(P(\lambda))$) equals the set $\Sigma(L)$.

We finish this subsection by giving a brief summary of the theory of Gilbert and Pearson [60] adapted to the Sturm–Liouville operator. The original paper of Gilbert and Pearson deals with the Schrödinger operator. Using the weighted measure $\kappa = y\,\mathrm{d}t$ instead of the Lebesgue measure on $\mathbb{R}$, we can prove the results stated in the following lines.

We define a set $\mathcal{M} \subset \mathbb{R}$ to be a minimal support for a measure ι on $\mathbb{R}$ if:

(1) $\iota(\mathbb{R} \setminus \mathcal{M}) = 0$;

(2) if $\mathcal{M}_0 \subset \mathcal{M}$ and $\iota(\mathcal{M}_0) = 0$, then $\ell(\mathcal{M}_0) = 0$, where ℓ is the Lebesgue measure on $\mathbb{R}$.

A minimal support of a measure ι determines where the measure is concentrated, and is defined up to a set of Lebesgue (and ι) 0 measure.

Let $E = \{\lambda \in \mathbb{R} \mid (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda)\text{exists}\}$, where ρ^+ is the spectral measure for Eq. (4.9) and $\mathrm{d}\rho^+/\mathrm{d}\ell$ is the Radon–Nikodym derivative of ρ^+ with respect to the measure ℓ. Note that $\mathrm{d}\kappa/\mathrm{d}\ell = y > 0$. Then $\ell(\mathbb{R} \setminus E) = 0$ and the minimal support $\mathcal{M}$ of ρ^+ has the decomposition $\mathcal{M} = \mathcal{M}_{ac} \cup \mathcal{M}_s = \mathcal{M}_{ac} \cup \mathcal{M}_{sc} \cup \mathcal{M}_p$, where $\mathcal{M}_{ac}$ and $\mathcal{M}_s$ are the absolutely continuous part and the singular part of $\mathcal{M}$ respectively. In particular

(i) $\mathcal{M} = \{\lambda \in \mathbb{R} \mid 0 < (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda) \leqslant \infty\}$,

(ii) $\mathcal{M}_{ac} = \{\lambda \in \mathbb{R} \mid 0 < (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda) < \infty\}$,

(iii) $\mathcal{M}_s = \{\lambda \in \mathbb{R} \mid (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda) = \infty\}$,

(iv) $\mathcal{M}_{sc} = \{\lambda \in \mathbb{R} \mid (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda) = \infty, \lim_{\delta\to 0^+} \rho^+(\lambda+\delta) - \rho^+(\lambda-\delta) = 0\}$,

(v) $\mathcal{M}_p = \{\lambda \in \mathbb{R} \mid (\mathrm{d}\rho^+/\mathrm{d}\ell)(\lambda) = \infty, \lim_{\delta\to 0^+} \rho^+(\lambda+\delta) - \rho^+(\lambda-\delta) > 0\}$.

Let $\lambda \in \mathbb{C}$. A solution $u_s(t,\lambda)$ of Eq. (4.9) is called *subordinate* at infinity if for every other linearly independent solution $u(t,\lambda)$ of Eq. (4.9), one has

$$\lim_{N\to\infty} \frac{\|u_s(t,\lambda)\|_N}{\|u(t,\lambda)\|_N} = 0,$$

where $\|\cdot\|_N$ denotes the $L^2((0,N), y)$-norm. Let $\alpha \in [0,\pi)$. Consider Eq. (4.9) together with the boundary condition (4.18) at $t = 0$, i.e.,

$$u(0)\cos\alpha + p(0)u'(0)\sin\alpha = 0.$$

The principal results of Gilbert and Pearson can be summarized as follows (see [60]):

THEOREM 4.11. *There exists a set* $E_1 \subset E$ *of full Lebesgue measure and full* ρ^+ *measure such that the nontangential limit*

$$\lim_{\varepsilon\to 0} m_+(\lambda + \mathrm{i}\varepsilon) = m_+(\lambda) \tag{4.20}$$

exists for every $\lambda \in E$, *and*

$$\frac{\mathrm{d}\rho^+}{\mathrm{d}\ell}(\lambda) = \frac{1}{\pi}\Im m_+(\lambda). \tag{4.21}$$

Moreover, we have

- (i) $\mathcal{M} = \{\lambda \in \mathbb{R} \mid 0 < \Im m_+(\lambda) \leqslant \infty\}$,
- (ii) $\mathcal{M}_{ac} = \{\lambda \in \mathbb{R} \mid 0 < \Im m_+(\lambda) < \infty\}$,
- (iii) $\mathcal{M}_s = \{\lambda \in \mathbb{R} \mid \Im m_+(\lambda) = \infty\}$,
- (iv) $\mathcal{M}_{sc} = \{\lambda \in \mathbb{R} \mid \Im m_+(\lambda) = \infty, \lim_{\delta\to 0^+} \rho^+(\lambda+\delta) - \rho^+(\lambda-\delta) = 0\}$,
- (v) $\mathcal{M}_p = \{\lambda \in \mathbb{R} \mid \Im m_+(\lambda) = \infty, \lim_{\delta\to 0^+} \rho^+(\lambda+\delta) - \rho^+(\lambda-\delta) > 0\}$

and

- (i) $\mathcal{M}^c = \{\lambda \in \mathbb{R} \mid$ *a subordinate solution of Eq.* (4.9) *exists and does not satisfy the boundary condition* (4.18)$\}$,
- (ii) $\mathcal{M}_{ac} = \{\lambda \in \mathbb{R} \mid$ *no subordinate solution of Eq.* (4.9) *exists*$\}$,
- (iii) $\mathcal{M}_s = \{\lambda \in \mathbb{R} \mid$ *a subordinate solution of Eq.* (4.9) *exists and satisfies the boundary condition* (4.18)$\}$,
- (iv) $\mathcal{M}_{sc} = \{\lambda \in \mathbb{R} \mid$ *a subordinate solution of Eq.* (4.9) *exists and satisfies the boundary condition* (4.18), *but it is not in* $L^2([0,\infty), y)\}$,
- (v) $\mathcal{M}_p = \{\lambda \in \mathbb{R} \mid$ *a subordinate solution of Eq.* (4.9) *exists, satisfies the boundary condition* (4.18) *and is in* $L^2([0,\infty), y)\}$.

Finally,

$$\Sigma^+(L) = \mathcal{M},$$

up to a set of 0 Lebesgue (*and* ρ^+) *measure.*

The theorem is still valid for Eq. (4.9) on $(-\infty, 0]$, with the spectral measure $\mathrm{d}\rho^-$ and the function m_-, with the appropriate changes of signs. From this theorem we derive the following important observations:

COROLLARY 4.12.

- (i) *The spectral measures* $\rho^\pm(\lambda)$, $P(\lambda)$ *increase exactly in the points of the spectra* $\Sigma^\pm(L)$, $\Sigma(L)$ *respectively;*
- (ii) *the nontangential limit* (4.20) *exists for Lebesgue a.e.* $\lambda \in \mathbb{R}$, $\Im m_+(\lambda) > 0$ ($\Im m_-(\lambda) < 0$) *for Lebesgue a.e* $\lambda \in \Sigma^+(L)$ ($\Sigma^-(L)$), *and* $\Im m_\pm(\lambda) = 0$ *for Lebesgue a.e.* $\lambda \in R^\pm(L)$;
- (iii) $|m_\pm(\lambda + \mathrm{i}\varepsilon)| \to \infty$ *for* $\varepsilon \to 0$ *if and only if* λ *is an eigenvalue of* $L^\pm$.

PROOF. The only thing we have to prove is that the measure $P(\lambda)$ increases exactly in the points of the spectrum $\Sigma(L)$. From Remark 4.9, the points of nonconstancy of $P(\lambda)$ are exactly the points of nonconstancy of the trace $\mathrm{Tr}(P(\lambda))$, and these are exactly the points λ for which

$$\Im\left(\frac{1}{m_-(\lambda)-m_+(\lambda)}+\frac{m_-(\lambda)m_+(\lambda)}{m_-(\lambda)-m_+(\lambda)}\right) \tag{4.22}$$

is positive. We now rewrite (4.22) in the following way

$$\Im\left(\frac{(1+m_-m_+)(\overline{m_- - m_+})}{\|m_- - m_+\|^2}\right). \tag{4.23}$$

From Theorem 4.11, it easy to conclude that (4.23) is not 0 exactly in the points of the spectrum. □

4.2. *The Sturm–Liouville equation as a nonautonomous differential system*

Let Ω be a compact metric space, and let $(\Omega, \{\tau_t\})$ be a flow. We suppose that there is a $\{\tau_t\}$-ergodic measure ν on Ω such that $\operatorname{Supp}\nu = \Omega$. We recall that the topological support $\operatorname{Supp}\nu$ of the measure ν is the complement of the largest open subset $U \subset \Omega$ satisfying $\nu(U) = 0$.

Suppose that $p, q, y : \Omega \to \mathbb{R}$ are continuous functions, and that p and y are strictly positive. For each $\omega \in \Omega$, we introduce the matrix function

$$t \mapsto \begin{pmatrix} 0 & \frac{1}{p(\omega\cdot t)} \\ q(\omega\cdot t)-\lambda y(\omega\cdot t) & 0 \end{pmatrix}$$

which by abuse of notation we call $\omega(t)$. We study the family of differential equations

$$\begin{pmatrix} \varphi \\ \psi \end{pmatrix}' = \begin{pmatrix} 0 & \frac{1}{p(\omega\cdot t)} \\ q(\omega\cdot t)-\lambda y(\omega\cdot t) & 0 \end{pmatrix}\begin{pmatrix} \varphi \\ \psi \end{pmatrix} \tag{SL_ω}$$

where ω ranges over Ω and λ is a complex parameter. If the function $p' : \Omega \to \mathbb{R} : \omega \mapsto \frac{\mathrm{d}}{\mathrm{d}t} p(\omega\cdot t)|_{t=0}$ is well defined and continuous, then (SL_ω) is equivalent to

$$-\big(p(\omega\cdot t)\varphi(t)'\big)' + q(\omega\cdot t)\varphi(t) = \lambda y(\omega\cdot t)\varphi(t). \tag{4.24_ω}$$

We have the following

PROPOSITION 4.13. *Suppose that* $\operatorname{Supp}\nu = \Omega$. *There is a set* $\Omega' \subset \Omega$ *with* $\nu(\Omega') = 1$ *and such that, if* $\omega \in \Omega'$, *then the orbit* $\{\omega\cdot t \mid t \in \mathbb{R}\}$ *is dense in* Ω. *Moreover,* Ω' *can be chosen such that each* $\omega \in \Omega'$ *is both positively and negatively Poisson recurrent.*

Recall that $\omega \in \Omega$ is positively (resp. negatively) Poisson recurrent if there is a sequence $\{t_n\} \to \infty$ (resp. $\{t_n\} \to -\infty$) such that $\lim_{n\to\infty} \omega \cdot t_n = \omega$.

PROOF. The proof is an easy consequence of the Birkhoff ergodic theorem. For, let $V_1, \dots, V_n, \dots$ be a countable base for the topology of Ω. Let χ_i be the characteristic function corresponding to V_i. Using the Birkhoff ergodic theorem, one checks easily that the sets $\Omega_i = \{\omega \in \Omega \mid \lim_{t\to\infty} \frac{1}{t}\int_0^t \chi_i(\omega \cdot s)\,\mathrm{d}s = \nu(V_i) > 0\}$ have ν-measure 1. It follows that if $\omega \in \Omega_i$, then the orbit of ω intersects V_i ($i \in \mathbb{N}$). It is clear now that each $\omega \in \Omega_i$ has dense orbit (in fact, it has dense positive semi-orbit). The set $\Omega' = \bigcap_{i=1}^{\infty} \Omega_i$ is the desired set.

The set Ω' consists of those points with dense positive semi-orbit; such points are in particular positively Poisson recurrent.

Using the fact that $\lim_{t\to-\infty} \frac{1}{t}\int_0^t \chi_i(\omega \cdot s)\,\mathrm{d}s = \nu(V_i)$ for ν-a.a. $\omega \in \Omega$, we see that there is a subset of Ω' of ν-measure 1 consisting of points which are negatively Poisson recurrent as well; we abuse notation slightly and let Ω' denote this set. This completes the proof. □

Let $\Phi_\omega(t)$ be the fundamental matrix solution of (SL_ω) with $\Phi_\omega(0) = I$. Define $\Sigma^{\mathrm{ed}}(L) = \{\lambda \in \mathbb{R} \mid$ the family (SL_ω) does NOT have exponential dichotomy$\}$, and $R^{\mathrm{ed}}(L) = \mathbb{C} \setminus \Sigma^{\mathrm{ed}}(L)$.

We next give a dichotomy-theoretic interpretation of the Weyl m-functions $m_\pm = m_\pm(\omega, \lambda)$ of Eqs. (4.24_ω) ($\omega \in \Omega$).

To begin with, let $\omega \in \Omega$ and $\lambda \in \mathbb{C} \setminus \Sigma^{\mathrm{ed}}(L)$. Define $m_+(\omega,\lambda)$ to be the unique (extended) complex number such that $\operatorname{Im} P_\omega = \operatorname{Span}\binom{1}{m_+(\omega,\lambda)}$. Here $m_+(\omega,\lambda) = \infty$ if and only if $\operatorname{Im} P_\omega = \operatorname{Span}\binom{0}{1}$. One can show that $\Im m_+(\omega,\lambda)\Im\lambda > 0$ whenever $\Im\lambda \neq 0$. In a similar way, we define $\operatorname{Ker} P_\omega = \operatorname{Span}\binom{1}{m_-(\omega,\lambda)}$ where $\Im m_-(\omega,\lambda)\Im\lambda < 0$ if $\Im\lambda \neq 0$. For every $\omega \in \Omega$, if $\Im\lambda \neq 0$ the maps $\lambda \mapsto m_\pm(\omega,\lambda)$ coincide with the classical Weyl m-functions of problem (4.24_ω). In fact, let $\omega \in \Omega$ and $\lambda \in \mathbb{C}$ with $\Im\lambda \neq 0$. Let $0 \neq u = (u_1, u_2) \in \mathbb{C}^2$ such that $\frac{u_2}{u_1} = m_+(\omega,\lambda)$ and let $u(t)$ be the solution of (SL_ω) with $u(0) = u$. Such a solution decays exponentially as $t \to \infty$, hence $u(t) \in L^2(0,\infty)$. Since (SL_ω) is in the limit-point case at ∞, the only L^2 solution at ∞ is $u(t)$. It is easy to check that $\frac{u_2}{u_1} = \frac{p(\omega)u_1'(0)}{u_1(0)}$. The same holds for $m_-(\omega,\lambda)$. We showed that the two definitions of the Weyl m-functions coincide. It follows that for each $\omega \in \Omega$, the maps $\lambda \mapsto m_\pm(\omega,\lambda)$ are holomorphic on $\mathbb{C} \setminus \mathbb{R}$ and meromorphic on $\mathbb{C} \setminus \Sigma^{\mathrm{ed}}(L)$.

The next proposition provides a result concerning the behavior of the Weyl m-functions when ω varies along an orbit.

PROPOSITION 4.14. *Let $\omega \in \Omega$ have dense orbit. Let $\bar\omega \in \Omega$ and let $\{t_n\} \subset \mathbb{R}$ be a sequence with $\lim_{n\to\infty} \omega \cdot t_n = \bar\omega$. Then the Weyl m functions $m_\pm(\omega \cdot t_n, \lambda)$ are well defined and*

$$\lim_{n\to\infty} m_\pm(\omega \cdot t_n, \lambda) = m_\pm(\bar\omega, \lambda),$$

uniformly on compact subsets of the upper (*lower*) *half-plane.*

PROOF. Let $\chi(t,\lambda)$ be a solution of Eq. (4.4) (in the interval $[0,b]$) satisfying the boundary conditions (4.4b) at $t=b$, and let $C_b(\lambda)$ be the circle defined by this solution as in Section 4.1. Let $D_b(\lambda)$ be the closure of $C_b(\lambda)$. Since $D_{b'}(\lambda)\subsetneq D_b(\lambda)$ for every $b'>b$, one has that $m_+(\omega,\lambda)$ is contained in every $D_b(\lambda)$. In an analogous way, we define the (closed) discs $D_b^n(\lambda)$ corresponding to $\omega\cdot t_n$. Let $\varepsilon>0$, and choose $b\in\mathbb{R}$ such that $\operatorname{diam} D_b(\lambda)<\varepsilon$. Fix any $b'>b$: it is easy to check that $C_{b'}^n(\lambda)$ converges to $C_{b'}(\lambda)$ as $n\to\infty$. This immediately implies that $|m_+(\omega\cdot t_n,\lambda)-m_+(\omega,\lambda)|<\varepsilon$. □

Now we turn to the first basic result concerning the spectrum of the family (SL_ω), namely (see [79])

PROPOSITION 4.15. *Let $\omega\in\Omega$ have dense orbit. Then a complex number λ lies in $R(L_\omega)$ if and only if the family (SL_ω) admits an exponential dichotomy: $R(L_\omega)=R^{\mathrm{ed}}(L)$.*

PROOF. Let $\lambda\in R^{\mathrm{ed}}(L)$: then the family (SL_ω) admits an exponential dichotomy over Ω. An easy consequence of the definition of the exponential dichotomy is that for every $\omega\in\Omega$, there exist two solutions $\varphi_\pm(\cdot,\omega,\lambda)$ of (4.24_ω) which are square integrable on the positive and negative half-lines respectively. Indeed $\varphi_\pm(\cdot,\omega,\lambda)$ are exponentially decreasing at ∞ and $-\infty$ respectively, for every $\omega\in\Omega$. Since $\varphi_\pm(\cdot,\omega,\lambda)$ are linearly independent, the Wronskian $W(\varphi_+,\varphi_-)=p(\varphi_+\varphi_-'-\varphi_+'\varphi_-)\neq 0$. It follows that a Green's function

$$G(t,s,\omega,\lambda)=\begin{cases}\dfrac{\varphi_+(t)\varphi_-(s)}{W(\varphi_+,\varphi_-)}y(s) & t\geqslant s,\\[2ex] \dfrac{\varphi_-(t)\varphi_+(s)}{W(\varphi_+,\varphi_-)}y(s) & t\leqslant s\end{cases}$$

is well defined, hence $\lambda\in R(L_\omega)$.

Conversely, assume that $\lambda\in R(L_\omega)$. We must prove that the family (SL_ω) admits exponential dichotomy over Ω. From a result of Sacker–Sell [137] and Selgrade [142], it is sufficient to show that the only bounded solution of the family is the trivial one. Suppose for contradiction that there exists $\bar\omega\in\Omega$ such that the corresponding differential equation $(\mathrm{SL}_{\bar\omega})$ has a nonzero bounded solution (hence $\lambda\notin R(L_{\bar\omega})$). Let $\{t_n\}\to\infty$ be a real sequence such that $\lim_{n\to\infty}\omega\cdot t_n=\bar\omega$. The Weyl m-functions $m_\pm(\omega\cdot t_n,\lambda)$ are defined, and $m_\pm(\omega\cdot t_n,\lambda)\to m_\pm(\bar\omega,\lambda)$ uniformly on every compact subset of the upper complex half-plane as $n\to\infty$ (see Proposition 4.14). It's clear then that the measure $\operatorname{Tr}P_n(\omega,\lambda):=\operatorname{Tr}P(\omega\cdot t_n,\lambda)$ weakly converges to $\operatorname{Tr}P(\bar\omega,\lambda)$ (note that the spectral matrix P depends on $\omega\in\Omega$). This means that for every $f\in C_c(\mathbb{R})$ we have

$$\int_{\mathbb{R}} f(\lambda)\,\mathrm{d}\big(\operatorname{Tr}P_n(\omega,\lambda)\big)\to\int_{\mathbb{R}} f(\lambda)\,\mathrm{d}\big(\operatorname{Tr}P(\bar\omega,\lambda)\big).$$

Since the resolvent set $R(L_\omega)$ is open, there is an interval I such that $\lambda\in I\subset R(L_\omega)$. Now, the resolvent set is invariant under the flow $(\Omega,\{\tau_t\})$ (in fact, one can easily check that if a Green's function corresponding to $\omega\in\Omega$ is well defined, then a Green's function corresponding to $\omega\cdot t\in\Omega$ is well defined as well, for every $t\in\mathbb{R}$), hence $\operatorname{Tr}P_n$ is constant on I. From Remark 4.10, it is straightforward to show that $\operatorname{Tr} P$ is constant on I, so $\lambda \in R(L_{\bar{\omega}})$, a contradiction. □

It will be often useful to think at the functions $p, q, y, m_\pm$ as functions of t, as follows: for every fixed $\omega \in \Omega$, we consider the map $t \mapsto p(\omega \cdot t)$ obtained by "following the orbit through $\omega \in \Omega$". The same holds for all the functions involved; for instance, for fixed $\omega \in \Omega$, we consider the maps $m_\pm(\cdot, \omega, \lambda) : t \mapsto m_\pm(\omega \cdot t, \lambda)$. We will often suppress the dependence with respect to $\omega \in \Omega$, unless it is strictly necessary.

If $\omega \in \Omega$, then $m_\pm(t, \omega, \lambda)$ is obtained from $m_\pm(\omega, \lambda)$ by "translating" the (unique) L^2 solutions at $\pm\infty$ of Eq. (4.24_ω): if we denote these solutions with $\varphi_\pm(t, \omega, \lambda)$, then

$$m_\pm(t, \omega, \lambda) = \frac{p(\omega \cdot t)\varphi'_\pm(t, \omega, \lambda)}{\varphi_\pm(t, \omega, \lambda)}.$$

Both m_+ and m_- are analytic in the upper and lower λ-half-planes respectively. The following proposition is fundamental.

PROPOSITION 4.16. *Let $\omega \in \Omega$. For every fixed $\lambda \in \mathbb{C}$ with $\Im\lambda \neq 0$ the Weyl m-functions $m_\pm(t, \lambda) \equiv m_\pm(t, \omega, \lambda)$ satisfy the Riccati equation*

$$m'_\pm(t, \lambda) + \frac{1}{p(t)} m^2_\pm(t, \lambda) = q(t) - \lambda y(t). \tag{4.25}$$

PROOF. Since

$$m_\pm(t, \lambda) = \frac{p(t)\varphi'_\pm(t)}{\varphi_\pm(t)},$$

differentiating with respect to t, we have

$$m'_\pm = \frac{(p\varphi'_\pm)'\varphi_\pm - p(\varphi'_\pm)^2}{\varphi^2_\pm}.$$

Hence

$$m'_\pm + \frac{1}{p} m^2_\pm = \frac{(p\varphi'_\pm)'}{\varphi_\pm} = q - \lambda y.$$

□

REMARK 4.17. Note that, if $\Im\lambda \neq 0$ and $\omega \in \Omega$, then

$$\varphi_\pm(t, \lambda) = \exp\left\{ \int_0^t \frac{m_\pm(s, \lambda)}{p(s)} \, \mathrm{d}s \right\} \tag{4.26}$$

is a solution of (4.24_ω) satisfying $\varphi_\pm(0, \lambda) = 1$ and $p(\omega)\varphi'_\pm(0, \lambda) = m_\pm(\omega, \lambda)$.

4.3. *The projective flow in the Sturm–Liouville setting*

We have already noted the importance of the projective flow in the study of nonautonomous differential systems. This subsection provides a further demonstration of this fact, since from the properties of the projective flow associated to a family of Sturm–Liouville differential systems, we will retrieve many important results concerning both the spectrum of the family (SL_ω) and the Weyl m-functions. We will use the notation and the terminology of Sections 2 and 3. Some proofs given in those sections will be repeated here, when they will lead to particular facts concerning the Sturm–Liouville operator.

Let Ω be a compact metric space, let $(\Omega, \{\tau_t\})$ be a real flow and let ν be a $\{\tau_t\}$-ergodic measure on Ω with $\operatorname{Supp}\nu = \Omega$. Consider the family of two-dimensional nonautonomous differential systems (SL_ω) defined as before. Let $(\Sigma, \mathbb{R})$ be the projective flow associated to $(\Omega, \mathbb{R})$, i.e. $\Sigma = \Omega \times \mathbb{P}(\mathbb{C})$ and $\hat{\tau}_t(\omega, l) = (\omega \cdot t, \Phi_\omega(t)l)$.

Fix $\omega \in \Omega$ and $\lambda \in \mathbb{R}$. The flow $(\Omega, \{\hat{\tau}_t\})$ induces a flow, which we still denote by $\{\hat{\tau}_t\}$, on $\Omega \times \mathbb{P}(\mathbb{R})$ as well. Following the developments of Section 2, we express Eqs. (SL_ω) in polar coordinates (r, θ), to obtain

$$\begin{cases} \dfrac{r'}{r} = \left(\dfrac{1}{p(\omega \cdot t)} + q(\omega \cdot t) - \lambda y(\omega \cdot t)\right)\sin\theta\cos\theta = f\big(\hat{\tau}_t(\omega, \theta)\big), \\ \theta' = \big(q(\omega \cdot t) - \lambda y(\omega \cdot t)\big)\cos^2\theta - \dfrac{1}{p(\omega \cdot t)}\sin^2\theta = g\big(\hat{\tau}_t(\omega, \theta)\big). \end{cases} \tag{4.27}$$

It is understood that we identify θ with the line through the origin it parametrizes, hence θ is taken mod π. If $\theta_0 \in \mathbb{P}(\mathbb{R})$ parametrizes the line l_0, then $\hat{\tau}_t(\omega, l_0) = \hat{\tau}_t(\omega, \theta_0) = (\omega \cdot t, \theta(t))$, where $\theta(t)$ satisfies the θ-equation in (4.27) with $\theta(0) = \theta_0$.

Recall that for every fixed $\omega \in \Omega$, the *rotation number* $\alpha_\omega(\lambda)$ is defined as

$$\alpha_\omega(\lambda) = -\lim_{t\to\infty} \frac{1}{t}\big(\theta(t, \lambda) - \theta_0(\lambda)\big) \quad (\lambda \in \mathbb{R}). \tag{4.28}$$

In the above formula, we explicitly wrote the fact that $\theta(\cdot)$ depends on the fixed $\lambda \in \mathbb{R}$. The questions we will answer in the following lines concern: (i) the existence of the limit (4.28); (ii) the independence of (4.28) with respect to the initial condition (ω, θ_0); (iii) continuity and monotonicity of the map $\lambda \mapsto \alpha(\lambda)$; (iv) the constancy of $\alpha(\lambda)$ in every interval $I \subset R^{\mathrm{ed}}(L)$. We will need the following

LEMMA 4.18. *Let $F : \Sigma \to \mathbb{R}$ be a continuous function such that $\int_\Sigma F(\sigma)\,\mathrm{d}\mu = 0$ for every invariant measure μ on Σ. Then $\frac{1}{t}\int_0^t F(\hat{\tau}_s(\sigma))\,\mathrm{d}s \to 0$ as $t \to \infty$, for all $\sigma \in \Sigma$. Moreover, the convergence is uniform with respect to $\sigma \in \Sigma$.*

PROOF. The proof uses techniques from Proposition 2.5; see, e.g. [89]. The space $C(\Sigma) = \{F : \Sigma \to \mathbb{R} \mid F \text{ is continuous}\}$ is separable, hence it contains a dense subset $C_1(\Sigma)$ which is generated by a countable family $\mathcal{F}$ of functions. We may assume that $F \in \mathcal{F}$. By contradiction, suppose that there exist sequences $\{t_n\} \to \infty$ and $\{\sigma_n\} = \{(\omega_n, \theta_n)\} \subset \Sigma$ such that

$$\frac{1}{t_n} \int_0^{t_n} F\big(\hat{\tau}_s(\sigma_n)\big)\,\mathrm{d}s \to \Delta(F) \neq 0.$$

We can assume that $\{\sigma_n\} \to \sigma = (\omega, \theta) \in \Sigma$. Let $F_1 \in \mathcal{F}$, and choose subsequences $\{t_n^{(1)}\} \subset \{t_n\}$ and $\{\sigma_n^{(1)}\} \subset \{\sigma_n\}$ such that

$$\lim_{t_n^{(1)} \to \infty} \frac{1}{t_n^{(1)}} \int_0^{t_n^{(1)}} F_1\big(\hat{\tau}_s\big(\sigma_n^{(1)}\big)\big)\,\mathrm{d}s$$

exists. Call it $\Delta(F_1)$. Continuing this way, for every $F_k \in \mathcal{F}$, we can find subsequences $\{t_n^{(k)}\} \subset \{t_n^{(k-1)}\}$ and $\{\sigma_n^{(k)}\} \subset \{\sigma_n^{(k-1)}\}$ such that

$$\lim_{t_n^{(k)} \to \infty} \frac{1}{t_n^{(k)}} \int_0^{t_n^{(k)}} F_k\big(\hat{\tau}_s\big(\sigma_n^{(k)}\big)\big)\,\mathrm{d}s$$

exists. Call it $\Delta(F_k)$. Now we choose the diagonal sequences $\{t_n^{(n)}\}$ and $\{\sigma_n^{(n)}\}$. For every $G \in \mathcal{F}$, one has

$$\Delta(G) = \lim_{t_n^{(n)} \to \infty} \frac{1}{t_n^{(n)}} \int_0^{t_n^{(n)}} G\big(\hat{\tau}_s\big(\sigma_n^{(n)}\big)\big)\,\mathrm{d}s.$$

Note that $\Delta(G)$ is $\mathbb{Q}$-linear, $\Delta(G) \geqslant 1$ if $G \geqslant 0$, and $\Delta(1) = 1$. It follows that the above limit defines a linear functional $l_1 : C_1(\Sigma) \to \mathbb{R}$ with $|l_1| = 1$, hence it extends to a unique linear functional $l : C(\Sigma) \to \mathbb{R}$ (here $|\cdot|$ denotes the L^∞ norm). By the Riesz representation theorem, l defines a measure μ_l on Σ such that $l(G) = \int_\Sigma G\,\mathrm{d}\mu_l$ for every $G \in C(\Sigma)$. Further, l is invariant in the sense that, if $t \in \mathbb{R}$ and $G \in C(\Sigma)$, then $l(G(\hat{\tau}_{-t}(\cdot))) = l(G(\cdot))$; this is because $t_n^{(n)} \to \infty$. But now we have

$$0 \neq \Delta(F) = \lim_{t_n^{(n)} \to \infty} \frac{1}{t_n^{(n)}} \int_0^{t_n^{(n)}} F\big(\hat{\tau}_s\big(\sigma_n^{(n)}\big)\big)\,\mathrm{d}s = \int_\Sigma F d\mu_l = l(F) = 0,$$

a contradiction. □

We use Lemma 4.18 in the proof of the following important theorem, which answers the questions (i), (ii) and (iii) posed before (for an analogous result in the case of the Schrödinger operator, see [89]).

THEOREM 4.19.

(a) *There exists a set* $\Omega_\nu \subset \Omega$ *with* $\nu(\Omega_\nu) = 1$, *such that* $\alpha_\omega(\lambda)$ *exists for every* $\omega \in \Omega_\nu$ *and does not depend on the choice of* $(\omega, \theta) \in \Omega_\nu \times \mathbb{P}(\mathbb{R})$: $\alpha_\omega(\lambda) = \alpha(\lambda)$, *for every* $\omega \in \Omega_\nu$;

(b) *if* ν *is the only ergodic measure on* Ω (*for instance if* $(\Omega, \mathbb{R})$ *is minimal and almost periodic*), *then* $\Omega_\nu = \Omega$, *and the limit* (4.28) *is uniform in* $t \in \mathbb{R}$ *and* $\sigma \in \Sigma$;

(c) *for every* $\omega \in \Omega$, *the maps* $\lambda \mapsto \alpha_\omega(\lambda)$ *are continuous, monotone nondecreasing, and* $\lim_{\lambda\to\infty} \alpha_\omega(\lambda) = +\infty$.

PROOF. Recall that the angular variable θ is defined mod π. First of all, we claim that the limit (4.28) does not depend on the choice of $\theta \in \mathbb{P}(\mathbb{R})$. For, let $0 < \theta_1 - \theta_0 < \pi$, and let $\sigma_1 = (\omega, \theta_1), \sigma_0 = (\omega, \theta_0) \in \Sigma$. It follows that $0 < \theta(t, \sigma_1) - \theta(t, \sigma_0) < \pi$ for all $t \in \mathbb{R}$, otherwise there would exists $t_0 \in \mathbb{R}$ such that $\theta(t_0, \sigma_1) - \theta(t_0, \sigma_0) = \pi$, and hence, by uniqueness, $\theta(t, \sigma_1) - \theta(t, \sigma_0)$ for all $t \in \mathbb{R}$, a contradiction. The claim now is obvious, since $|\theta(t, \sigma_1) - \theta(t, \sigma_0)|$ is bounded, for every $t \in \mathbb{R}$ and $\sigma_0, \sigma_1 \in \Sigma$.

Now, let μ be a $\{\hat{\tau}_t\}$-ergodic measure on Σ. Using the Birkhoff ergodic theorem, one finds a set Σ_μ with $\mu(\Sigma_\mu) = 1$ and such that the limit (4.28) exists for all $\sigma \in \Sigma_\mu$. Moreover we have

$$\alpha_\omega(\lambda) = -\int_\Sigma g(\omega, \theta)\, \mathrm{d}\mu,$$

hence the limit (4.28) does not depend on the choice of $(\omega, \theta) \in \Sigma_\mu$. Note that if ν is any $\{\tau_t\}$-ergodic measure on Ω, then $\Omega_\nu := \pi(\Sigma_\mu)$ has ν-measure 1. From the observations above, the function $g(\cdot) : \Sigma \to \mathbb{R}$ can be viewed as a function of the single variable $\omega \in \Omega$, since, when it exists, the limit (4.28) is independent of the choice of $\theta \in \mathbb{P}(\mathbb{R})$. It follows that for every $\omega \in \Omega_\nu$, the limit (4.28) exists and does not depend on the choice of $\omega \in \Omega_\nu$. We have proved (a).

To prove (b), we use Lemma 4.18. Let μ be any invariant measure on Σ. Then, by the Birkhoff ergodic theorem we conclude that there exists a set Σ_μ with $\mu(\Sigma_\mu) = 1$, and such that the limit (4.28) exists for all $\sigma = (\omega, \theta) \in \Sigma_\mu$. This limit defines a function $g^* : \Sigma_\mu \to \mathbb{R}$, which is μ-integrable and such that

$$\int_\Sigma g^*(\sigma)\, \mathrm{d}\mu = \int_\Sigma g(\sigma)\, \mathrm{d}\mu.$$

Arguing as above, the function g^* can be viewed as a function of the single variable $\omega \in \Omega$. Now we use the unique ergodicity of Ω. Since g^* is invariant with respect to the flow $(\Omega, \{\tau_t\})$, we conclude that $g^* = const$ on a set $\Omega_\nu \subset \Omega$ with $\nu(\Omega_\nu) = 1$. By the Birkhoff ergodic theorem, this constant is exactly the rotation number $\alpha(\lambda)$. At this point, (b) follows easily, applying Lemma 4.18 to the function $g(\cdot) + \alpha$.

To prove (c), let $\{\lambda_j\} \subset \mathbb{R}$ be a sequence which converges to $\lambda_0 \in \mathbb{R}$. Let $g_j(\sigma) = g(\sigma, \lambda_j)$, $g_0(\sigma) = g(\sigma, \lambda_0)$, and let $(\Sigma, \{\hat{\tau}_t^j\})$ be the corresponding projective flows (depending on λ_j). Let μ_j be any $\{\hat{\tau}_t^j\}$-ergodic measure on Σ. Then

$$\alpha(\lambda_j) = -\int_\Sigma g_j(\sigma)\, \mathrm{d}\mu_j.$$

Without loss of generality, we may assume that μ_j weakly converges to $\tilde{\mu}$, where $\tilde{\mu}$ is a $\{\hat{\tau}_t\}$-invariant measure on Σ. It follows that

$$\int_\Sigma g_0(\sigma)\,\mathrm{d}\mu_j \to \int_\Sigma g_0(\sigma)\,\mathrm{d}\tilde{\mu}.$$

Moreover

$$\left|g_j(\sigma) - g_0(\sigma)\right| \leqslant \max_{\omega\in\Omega}\left|y(\omega)\right| \cdot |\lambda_j - \lambda_0| \to 0$$

as $j \to \infty$. Using this inequality, we obtain

$$\alpha(\lambda_j) = -\int_\Sigma g_j(\sigma)\,\mathrm{d}\mu_j = -\int_\Sigma (g_j - g_0)(\sigma)\,\mathrm{d}\mu_j - \int_\Sigma g_0(\sigma)\,\mathrm{d}\mu_j \to \alpha(\lambda)$$

as $j \to \infty$. The monotonicity property and the asymptotic behavior of the map $\lambda \mapsto \alpha(\lambda)$ follow directly from the definition of the rotation number. ☐

REMARK 4.20. Any zero of the solution φ of Eq. (4.24$_\omega$) corresponds to a value $\bar{t} \in \mathbb{R}$ such that $\theta(\bar{t}, \lambda) = \frac{\pi}{2} \bmod \pi$. By (4.27), one has $\theta'(\bar{t}) = -\frac{1}{p(\omega\cdot\bar{t})} < 0$. It follows that θ decreases at such zero: this shows that there is exactly one more zero every time θ is increased by π. Let $N(t, \lambda)$ be the number of the zeros of the solution φ of (4.24$_\omega$) in $[0, t]$. Then we must have

$$\alpha(\lambda) = \pi \lim_{t\to\infty} \frac{1}{t} N(t, \lambda). \tag{4.29}$$

There remains to discuss the assertion that $\alpha(\lambda)$ is constant in every open interval $I \subset R^{\mathrm{ed}}(L)$. Actually, this and other considerations will enable us to prove a key fact concerning the spectrum of the family (SL$_\omega$). In fact, we will see that the points of growth of $\alpha(\lambda)$ *coincide* with the points of the spectrum $\Sigma(L_\omega)$, for Lebesgue a.a. $\lambda \in \mathbb{R}$. Since $\alpha(\lambda)$ does not depend on ω, for ν-a.a. $\omega \in \Omega$, it follows that $\Sigma(L_\omega)$ equals a fixed closed set $\Sigma(L)$ for ν-a.a. $\omega \in \Omega$. Moreover $\Sigma(L) = \Sigma^{\mathrm{ed}}(L)$.

We summarize these last remarks in the following theorem. In the remainder of Section 4.3 we will discuss its proof together with various facts concerning the spectral theory of the family (SL$_\omega$). We will also illustrate several methods which have proved useful in the study of 2-dimensional, nonautonomous linear systems.

THEOREM 4.21.

(i) *For ν-a.a. $\omega \in \Omega$, say $\omega \in \Omega_\nu$, the spectrum of Eq.* (4.24$_\omega$) *equals a closed set $\Sigma(L)$ which does not depend on $\omega \in \Omega_\nu$. Also, $R^{\mathrm{ed}}(L) = R(L)$; i.e., $R(L) := \mathbb{C} \setminus \Sigma(L) =$ $\{\lambda \in \mathbb{C} \mid$ the family* (SL$_\omega$) *has an exponential dichotomy over* $\Omega\}$.

(ii) *The set $\Sigma(L)$ contains no isolated points.*

(iii) *If $I \subset \mathbb{R}$ is an open interval, then $I \subset R(L)$ if and only if the rotation number α is constant on I.*

First, we note that Propositions 4.13 and 4.15 imply that there is a set $\Omega_\nu \subset \Omega$ with $\nu(\Omega_\nu) = 1$ such that, if $\omega \in \Omega_\nu$, then the spectrum of Eq. (4.24$_\omega$) equals the complement in $\mathbb{R}$ of $R^{\mathrm{ed}}(L)$. Thus point (i) of Theorem 4.21 has already been proved.

Second, we turn to a proof of the above mentioned constancy property of the rotation number. We need some arguments of Schwarzmann [140]. We sketch some facts of his theory. Let $H(\Omega, S^1)$ be the set of all the homotopy classes of the maps $f : \Omega \to S^1 \subset \mathbb{C}$. Each class in $H(\Omega, S^1)$ contains a map f such that the map $f' : \Omega \to \mathbb{C} : \omega \mapsto \frac{\mathrm{d}}{\mathrm{d}t} f(\omega \cdot t)_{|t=0}$ is well defined and continuous. Let $h : H(\Omega, S^1) \to \mathbb{R}$ be defined as follows: $h[f] = \Im \int_\Omega \frac{f'(\omega)}{f(\omega)} \mathrm{d}\nu(\omega)$, where, as usual, ν is a $\{\tau_t\}$-ergodic measure on Ω. Using the Birkhoff ergodic theorem, one can show that for ν-a.a. $\omega \in \Omega$, $h[f]$ equals $\lim_{t\to\infty} \frac{1}{t} \arg f(\omega \cdot t)$. Schwarzmann proved that the map h induces a homomorphism between the groups $H(\Omega, S^1)$ and $(\mathbb{R}, +)$. For, let C be the subgroup of $H(\Omega, S^1)$ consisting on the homotopy classes of the maps $g(\omega) = \mathrm{e}^{2\mathrm{i}s(\omega)}$, where $s : \Omega \to \mathbb{R}$ is a given continuous function. For every $g \in C$, one has $h[g] = 0$, hence the map h induces a homomorphism from $\tilde{H}(\Omega, \mathbb{Z}) = H(\Omega, S^1)/C$ into $(\mathbb{R}, +)$. This homomorphism is called the "Schwarzmann homomorphism". We can now prove the following result:

THEOREM 4.22. *Let $I \subset R(L) \cap \mathbb{R}$ be an open interval. Then $\alpha(\lambda)$ is constant in I.*

PROOF. We use the Schwarzmann homomorphism. Let us temporarily identify the projective circle $\mathbb{P}(\mathbb{R})$ with the circle $S^1 \in \mathbb{C}$ by mapping the line l parametrized by $\theta \in \mathbb{R}$ to $\mathrm{e}^{2\mathrm{i}\theta} \in S^1$ (recall that θ is a π-periodic coordinate on $\mathbb{P}(\mathbb{R})$). Let $i : \mathbb{P}(\mathbb{R}) \to S^1$ denote this map. Next note that, for each fixed $\lambda \in I$, the map $\tilde{g}_\lambda : \Omega \to \mathbb{P}(\mathbb{R}) : \omega \mapsto m_+(\omega, \lambda)$ is a continuous function. The composition $g_\lambda = i \circ \tilde{g}_\lambda$ lies in $H(\Omega, S^1)$.

Let us now calculate the image of g_λ under the Schwarzmann homomorphism h. Let $\omega \in \Omega$, and let θ_0 be a parameter value of $m_+(\omega, \lambda)$. Let $\theta(t)$ be the solution of (4.27) with initial value θ_0. We then obtain for ν-a.a. $\omega \in \Omega$:

$$-h[g_\lambda] = -2 \lim_{t\to\infty} \frac{\theta(t)}{t} = 2\alpha(\lambda).$$

This shows that $2\alpha \in h(\tilde{H}(\Omega, \mathbb{Z}))$, and the continuity of $\alpha(\lambda)$ implies that $\alpha(\lambda)$ is constant on I. □

The other useful quantity in the study of nonautonomous differential systems is the upper Lyapunov exponent $\beta(\lambda)$. It has been already defined and studied in detail in Section 2. All the properties of $\beta(\lambda)$ which were stated in that section retain validity in our case.

It is convenient to extend the concepts of the rotation number and the Lyapunov exponent to complex λ. To do this we define the Floquet exponent. We write z instead of λ, and use λ to denote real numbers.

Fix $z \in \mathbb{C}$ with $\Im z \neq 0$, and recall that for the family (SL$_\omega$), the Weyl m-functions are defined. Such functions satisfy the Riccati equation (4.25).

Let $\omega \in \Omega$ be fixed. For $\Im z \neq 0$ we define the Floquet exponent $w(\omega, z)$ as follows

$$w(\omega, z) = \frac{1}{2} \lim_{t\to\infty} \frac{1}{t} \int_0^t \frac{1}{p(\omega \cdot s)} \big(m_+(\omega \cdot s, z) - m_-(\omega \cdot s, z)\big)\, \mathrm{d}s. \tag{4.30}$$

Using the Birkhoff ergodic theorem, one sees that, for a fixed ergodic measure ν on Ω,

$$w(\omega, z) = \frac{1}{2}\int_\Omega \frac{[m_+(\omega, z) - m_-(\omega, z)]}{p(\omega)}\, \mathrm{d}\nu(\omega) = w(z), \tag{4.31}$$

for ν-a.a. $\omega \in \Omega$. In particular, it follows that $w(\omega, z)$ does not depend on the choice of $\omega \in \Omega$, for ν-a.a $\omega \in \Omega$, and we will write simply $w(z)$ instead of $w(\omega, z)$.

We have the following

PROPOSITION 4.23. *For* $\Im z \neq 0$, *we have*

$$w(z) = \int_\Omega \frac{1}{p(\omega)} m_+(\omega, z)\, \mathrm{d}\mu = -\int_\Omega \frac{1}{p(\omega)} m_-(\omega, z)\, \mathrm{d}\mu. \tag{4.32}$$

PROOF. For fixed $\omega \in \Omega$, consider the map (where the notation has an obvious meaning)

$$f(t, z) = \frac{m_+(t, z) + m_-(t, z)}{p(t)} = \frac{\varphi_+'(t, z)\varphi_-(t, z) + \varphi_-'(t, z)\varphi_+(t, z)}{\varphi_+(t, z)\varphi_-(t, z)}.$$

It is obvious that f is the derivative with respect to t of the function

$$\ln\bigl(\varphi_+(t, z)\varphi_-(t, z)\bigr).$$

Integrating between 0 and t we obtain

$$\begin{aligned}\int_0^t \frac{1}{p(s)}\bigl[m_+(s, z) + m_-(s, z)\bigr]\, \mathrm{d}s = {} & \ln\bigl(\varphi_+(t, z)\varphi_-(t, z)\bigr) \\ & - \ln\bigl(\varphi_+(0, z)\varphi_-(0, z)\bigr).\end{aligned}$$

If we divide both sides by t and pass to the limit as $t \to \infty$, we obtain (4.32). □

From (4.26), the solutions $\varphi_\pm(t, \lambda)$ have the asymptotic form

$$\varphi_\pm(t, \lambda) \sim \mathrm{e}^{\pm(\Re w(\lambda)t + i\Im w(\lambda)t)}. \tag{4.33}$$

It is quite natural to define the Lyapunov exponent and the rotation number for complex z in the following way:

DEFINITION 4.24. Let $z \in \mathbb{C} \setminus \mathbb{R}$. We define

$$\tilde{\beta}(z) = \Re w(z) \quad \text{(Lyapunov exponent)}$$

and

$$\tilde{\alpha}(z) = \Im w(z) \quad \text{(Rotation number)}.$$

Now we prove important results of convergence. Recall that for Lebesgue a.a. $\lambda \in \mathbb{R}$ there exists the nontangential limit of $m_\pm(z)$ as $z \to \lambda$, and that $|m_\pm(z)| \to \infty$ as $z \to \lambda$ if and only if λ is an eigenvalue for the operator $L^\pm$ respectively (see again Theorem 4.11 and Corollary 4.12).

Moreover, if $z \in \mathbb{C}$ is such that $\Im z \neq 0$, then the projective flow $(\Sigma, \mathbb{R})$ is defined as $(\Sigma = \Omega \times \mathbb{P}(\mathbb{C}), \{\hat{\tau}_t\})$, where $\{\hat{\tau}_t\}$ is the skew-product flow induced by $\{\tau_t\}$ and the solutions of (SL_ω). We prove the following

PROPOSITION 4.25. *For every* $\lambda \in \mathbb{R}$,

$$\lim_{\varepsilon \to 0} \tilde{\beta}(\lambda + \mathrm{i}\varepsilon) = \beta(\lambda). \tag{4.34}$$

PROOF. Recall that we have only two possibilities for $\lambda \in \mathbb{R}$: namely, either $\beta(\lambda) = 0$ or $\beta(\lambda) < 0$.

For every z with $\Im z \neq 0$ the Weyl m-function $m_+(z)$ defines an invariant (minimal) section in Σ, hence an ergodic measure μ_z on Σ expressed as follows

$$\int_\Sigma f(\sigma)\,\mathrm{d}\mu_z = \int_\Omega f\bigl(\omega, m_+(\omega, z)\bigr)\,\mathrm{d}\nu(\omega), \tag{4.35}$$

for every continuous function $f : \Sigma \to \mathbb{R}$. It is easy to check that μ_z is indeed $\{\hat{\tau}_t\}$-ergodic and that it projects to ν. Next, for every $z \in \mathbb{C}$, we define a continuous function $f_z : \Sigma \to \mathbb{R}$ as follows:

$$f_z(\sigma) = \Re \frac{\langle [y(\omega)\left(\begin{smallmatrix} 0 & 0 \\ -z & 0 \end{smallmatrix}\right) + C(\omega)]u, u\rangle}{\langle u, u\rangle}, \tag{4.36}$$

where $\sigma = (\omega, l) \in \Sigma$, u is any nonzero vector in l, $\langle \cdot, \cdot \rangle$ is the usual inner product in $\mathbb{C}$, and

$$C(\omega) = \begin{pmatrix} 0 & 1/p(\omega) \\ q(\omega) & 0 \end{pmatrix}.$$

For every sequence $z_n \to \lambda$, f_{z_n} converges to f_λ uniformly on Σ. Moreover, if $u(t)$ is any nonzero solution of Eq. (SL_ω), then

$$\frac{1}{t} \ln \frac{|u(t)|}{|u(0)|} = \frac{1}{t} \int_0^t f_z\bigl(\hat{\tau}_s(\omega, l_u)\bigr)\,\mathrm{d}s, \tag{4.37}$$

where l_u is the line in $\mathbb{C}$ containing 0 and $u(0)$.

From the Birkhoff ergodic theorem, (4.37), the definition of μ_z, and (4.33), we have

$$\tilde{\beta}(z) = \int_\Sigma f_z(\sigma)\,\mathrm{d}\mu_z = \int_\Omega f_z\bigl(\omega, m_+(\omega, z)\bigr)\,\mathrm{d}\nu \quad (\Im z > 0). \tag{4.38}$$

Suppose first that $\beta(\lambda) = 0$. Simple applications of the Choquet theorem [131], the Oseledets theorem [8,129] and the Birkhoff ergodic theorem show that for every invariant measure μ on Σ, we have

$$\int_\Sigma f_\lambda(\sigma)\,\mathrm{d}\mu = 0. \tag{4.39}$$

In fact, suppose that there exists an invariant measure μ on Σ such that

$$\int_\Sigma f_\lambda(\sigma)\,\mathrm{d}\mu < 0.$$

Then we apply the Choquet theorem to the set Γ of the $\{\hat{\tau}_t\}$-invariant measures on Σ which project to ν (Γ is weak-$*$ compact and convex), to show that there exists an ergodic measure μ_1 on Σ such that $\int_\Sigma f\,\mathrm{d}\mu_1 = \eta < 0$. Now, use the Birkhoff ergodic theorem to find a set $\Sigma_1 \subset \Sigma$ with $\mu_1(\Sigma_1) = 1$, and such that

$$\lim_{|t|\to\infty} \frac{1}{t}\int_0^t f\big(\hat{\tau}_s(\sigma)\big)\,\mathrm{d}s = \eta, \quad \text{for all } \sigma \in \Sigma_1.$$

Since $\beta(\lambda) = 0$, we apply the Oseledets theorem to find a set Ω_* with $\nu(\Omega_*) = 1$ and such that, if θ_0 is any initial value, then

$$\lim_{|t|\to\infty} \frac{1}{t}\int_0^t f\big(\hat{\tau}_s(\omega,\theta_0)\big)\,\mathrm{d}s = 0, \quad \text{for all } a \in \Omega_*.$$

Let $\Omega_1 = \pi(\Sigma_1)$, and choose $\omega \in \Omega_1 \cap \Omega_*$. Take points $(\omega, l_1) \in \Sigma_1$, $(\omega, l_2) \in \Sigma_2 = \pi^{-1}(\Omega_*)$. Clearly $l_1 \neq l_2$. If we let x_1, x_2 be unit vectors in l_1 and l_2 respectively, then x_1 and x_2 are linearly independent. Let $x_i(t) = \Phi_\omega(t)x_i$ $(i = 1, 2)$. Let $\Psi(t)$ be the fundamental matrix solution of (SL_ω) whose columns are $x_1(t)$ and $x_2(t)$. By Liouville's formula, we argue that $\det\Psi(t) = \det\Psi(0) = \text{const.}$ for all $t \in \mathbb{R}$. But also $\lim_{t\to-\infty}\det\Psi(t) = 0$, a contradiction.

We claim now that, if $\beta(\lambda) = 0$, then $\tilde{\beta}(z)$ converges to $\beta(\lambda)$ as $z \to \lambda$, and this convergence need not be nontangential, i.e. is nonrestricted. Suppose for contradiction that there exists a sequence $\{z_n\}$ of complex numbers converging to λ and such that

$$\tilde{\beta}(z_n) \to \beta^* \neq \beta(\lambda).$$

Using weak compactness of measures, we can assume that $\mu_{z_n} \rightharpoonup \mu_\lambda$, where μ_λ is invariant with respect to the flow $(\Sigma, \{\hat{\tau}_t^{(\lambda)}\})$. So we have, using Lemma 4.18,

$$\tilde{\beta}(z_n) = \int_\Sigma f_{z_n}(\sigma)\,\mathrm{d}\mu_{z_n} \to \int_\Sigma f_{z_n}(\sigma)\,\mathrm{d}\mu_\lambda \to \int_\Sigma f_\lambda(\sigma)\,\mathrm{d}\mu_\lambda = 0,$$

a contradiction.

Now we consider the case when $\beta(\lambda) < 0$. From the Oseledets theorem 2.1, there is a set $\Omega_\nu \subset \Omega$ with $\nu(\Omega_\nu) = 1$ which has the following property: if $\omega \in \Omega_\nu$, there is a vector $0 \neq u \in \mathbb{R}^2$ such that

$$\lim_{t\to\infty} \ln\left|\Phi_\omega(t)u\right| = \beta(\lambda) < 0. \tag{4.40}$$

In particular, it follows that the solution $\Phi_\omega(t)u \in L^2(0,\infty)$. Using Liouville's formula, one checks that u is unique up to a constant multiple.

Let $l_\omega \in \mathbb{P}(\mathbb{R})$ be the line containing u. Then l_ω contains the unit vector $\left(\begin{smallmatrix}\cos\alpha\\ \sin\alpha\end{smallmatrix}\right)$ for exactly one number $\alpha \in [0,\pi)$. Consider the following spectral problem:

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t}\left(p(\omega\cdot t)\dfrac{\mathrm{d}\varphi}{\mathrm{d}t}\right) - q(\omega\cdot t)\varphi = -zy(\omega\cdot t)\varphi, \quad t \in [0,\infty), \\ \varphi(0) = \cos\alpha. \\ p(0)\varphi'(0) = \sin\alpha. \end{cases} \tag{$*$}$$

Note that the number λ which we are considering is an eigenvalue of this spectral problem. As stated previously, a Weyl m-function $m_+(\alpha,\omega,z)$ is associated to the spectral problem $(*)$; see Proposition 4.5 and the discussion preceding it. We have

$$m_+(\omega,z) = m_+(\pi/2,\omega,z) \quad (\Im z > 0);$$

see Remark 4.6.

Let us temporarily write

$$m_\alpha(z) = m_+(\alpha,\omega,z), \qquad m(z) = m_+(\omega,z).$$

One can check that

$$m(z) = -\frac{\cos\alpha - m_\alpha(z)\sin\alpha}{\sin\alpha + m_\alpha(z)\cos\alpha} \quad (\Im z \neq 0)$$

(see Remark 4.6 again). Now, an analogue of the Gilbert–Pearson theory is valid for the spectral problem $(*)$; in particular, there holds a statement corresponding to point (iii) in Corollary 4.12. This means that

$$m_\alpha(z) \to \infty \quad \text{when } z \to \lambda \text{ nontangentially.}$$

This in turn means that $m(z) \to \tan\alpha$ as $z \to \lambda$ nontangentially. That is, if we identify $m(z)$ with the complex line it parametrizes, we have

$$m(z) \to l_\omega \quad \text{when } z \to \lambda \text{ nontangentially.}$$

We conclude that, if $z \to \lambda$ nontangentially, then $f_z(\omega, m_+(\omega,z)) \to f_\lambda(\omega, l_\omega)$ for all $\omega \in \Omega_\nu$. Using (4.38), we obtain

$$\tilde{\beta}(z) = \int_\Omega f_z\big(\omega, m_+(\omega, z)\big)\,\mathrm{d}\nu \to \int_\Omega f_\lambda(\omega, l_\omega)\,\mathrm{d}\nu = \beta(\lambda). \qquad \square$$

Now we turn to $\Im w(z)$, and prove an analogous proposition, i.e.

PROPOSITION 4.26. *For every $\lambda \in \mathbb{R}$, we have*

$$\lim_{\varepsilon\to 0} \tilde{\alpha}(\lambda + \mathrm{i}\varepsilon) = \alpha(\lambda). \tag{4.41}$$

PROOF. Before proving this proposition, we want to give an equivalent definition of the rotation number for each complex number z with $\Im z \neq 0$. Let $\omega \in \Omega$. For $\Im z > 0$, consider a solution $u(t)$ of (4.24_ω) such that

$$\Im W[u, \bar{u}] > 0, \tag{4.42}$$

where $W[u, v] = p(uv' - uv')$ is the Wronskian of u and v. Note that $W[u, \bar{u}]$ is not constant, since $\bar{u}(t)$ is not a solution of (4.24_ω).

Let

$$h(t, z) = -\frac{1}{t} \arg \frac{u(t, z)}{u(0, z)} = -\frac{1}{t} \int_0^t \Im \frac{u'(s, z)}{u(s, z)}\,\mathrm{d}s. \tag{4.43}$$

We define the rotation number as the limit

$$\lim_{t\to\infty} h(t, z). \tag{4.44}$$

Suppose for the moment that the limit (4.44) exists and does not depend on the particular choice of the solution. Then

$$\lim_{t\to\infty} h(t, z) = \lim_{t\to\infty} \frac{1}{t} \int_0^t \frac{\Im m_+(s, z)}{p(s)}\,\mathrm{d}s = -\lim_{t\to\infty} \frac{1}{t} \int_0^t \frac{\Im m_-(s, z)}{p(s)}\,\mathrm{d}s = \tilde{\alpha}(z), \tag{4.45}$$

and the given definitions turn out to be equivalent. To prove the existence of the limit (4.44), and its invariance with respect to the particular solution, we may proceed as follows. Since $\Im W[u, \bar{u}] = -2p|u|^2 \Im \frac{u'}{u}$, the assumption (4.42) is equivalent to

$$\Im \frac{u'}{u} < 0, \tag{4.46}$$

hence $h(t, z) > 0$. Now, let v any other solution of (4.24_ω) satisfying (4.42). We may assume that $v(0, z) = 1 = u(0, z)$ (the assumption (4.42) retains validity if we replace u by cu, where c is a non zero constant). We claim that

$$\left| \int_0^t \Im \left(\frac{u'}{u} - \frac{v'}{v} \right) \mathrm{d}s \right| < \pi. \tag{4.47}$$

If true, this proves that if the limit exists for a particular solution, then it exists for any other solution, and does not depend on the choice of the solution. Let us prove the claim. The assumption (4.42) implies that both $\Im u'(0,z)$ and $\Im v'(0,z)$ are negative. If our claim were false, then there would exist $t^* > 0$ such that $\arg(u(t^*,z) - v(t^*,z)) = \pm\pi$, and so there would exist a positive constant c such that

$$u(t^*,z) + cv(t^*,z) = 0.$$

But $u + cv$ is a solution of (4.24_ω) satisfying (4.42), which in turn implies that $u + cv$ has no zeros, a contradiction. The existence of the limit follows easily.

Now we turn to the proof of Proposition 4.26. The function $w(z)$ is analytic in the upper complex half plane and has positive imaginary part there: hence it is an Herglotz function. From the theory of Herglotz functions [36], there is a nondecreasing function $\rho(\lambda)$ such that

$$\Im w(z) = \Im z \int_{-\infty}^{\infty} \frac{\mathrm{d}\rho(\lambda)}{|\lambda - z|^2} + c,$$

where c is a constant (it is well known that the asymptotic behavior of m_+ as $\Im z \to \infty$ ensures that $c = 0$). In addition the following relation holds

$$\rho(\lambda_2) - \rho(\lambda_1) = \frac{1}{\pi} \lim_{\varepsilon \to 0} \int_{\lambda_1}^{\lambda_2} \Im w(\lambda + \mathrm{i}\varepsilon)\,\mathrm{d}\lambda$$

at all continuity points of ρ. If $\{w_n(z)\}$ is a sequence of analytic functions with $\Im w_n(z) > 0$ if $\Im z > 0$, and if $w_n(z) \to w(z)$ pointwise, then we have that the corresponding sequence of measures $\{\mathrm{d}\rho_n(\lambda)\}$ weakly converges to $\mathrm{d}\rho(\lambda)$ (with abuse of notation).

Let $\Im z > 0$, and put

$$h(t,z) = -\frac{1}{t} \int_0^t \Im \frac{\varphi_+'(s,z)}{\varphi_+(s,z)}\,\mathrm{d}s.$$

For every fixed $t \in \mathbb{R}$, the map $z \mapsto h(t,z)$ is analytic in the upper complex half plane, has positive imaginary part, and pointwise converges to $\Im w(z)$ as $t \to \infty$. It follows that the corresponding densities define measures which are weakly convergent to the measure $\mathrm{d}\rho(\lambda)$. If we denote these densities by $\rho(t,\lambda)$ we obtain easily

$$\rho(t,\lambda_2) - \rho(t,\lambda_1) = \frac{1}{\pi} \int_{\lambda_1}^{\lambda_2} h(t,\lambda)\,\mathrm{d}\lambda,$$

since $h(t,\lambda)$ is continuous for $\Im z \geqslant 0$. Using the fact that, as $t \to \infty$, $\rho(t,\lambda)$ converges to $\rho(\lambda)$ at all points λ of continuity of ρ, we can write

$$\rho(\lambda_2) - \rho(\lambda_1) = \frac{1}{\pi} \lim_{t \to \infty} \int_{\lambda_1}^{\lambda_2} h(t,\lambda)\,\mathrm{d}\lambda$$

at all continuity points λ_1, λ_2 of ρ.

Recall that if $\lambda \in \mathbb{R}$, then $h(t,\lambda) \to \alpha(\lambda)$ as $t \to \infty$ (this is an easy consequence of Corollary 4.12). Using Sturm's comparison theorem we can also prove that this convergence is bounded on $[\lambda_1, \lambda_2]$, hence we can write

$$\rho(\lambda_2) - \rho(\lambda_1) = \frac{1}{\pi} \int_{\lambda_1}^{\lambda_2} \alpha(\lambda)\,\mathrm{d}\lambda.$$

From these facts we obtain

$$\Im w(z) = \tilde{\alpha}(z) = \frac{\Im z}{\pi} \int_{\mathbb{R}} \frac{\alpha(\lambda)\,\mathrm{d}\lambda}{|\lambda - z|^2}, \quad \Im z > 0. \tag{4.48}$$

Next we put $z = \eta + \mathrm{i}\varepsilon$ and compute the limit for $\varepsilon \to 0$: we have, using standard arguments,

$$\lim_{\varepsilon \to 0} \tilde{\alpha}(\eta + \mathrm{i}\varepsilon) = \lim_{\varepsilon \to 0} \frac{\varepsilon}{\pi} \int_{\mathbb{R}} \frac{\alpha(\lambda)\,\mathrm{d}\lambda}{(\lambda - \eta)^2 + \varepsilon^2} = \alpha(\eta)$$

for all $\eta \in \mathbb{R}$. □

REMARK 4.27. Using (4.48), we can obtain the following representation

$$\frac{w(z) - w(z_0)}{z - z_0} = \frac{1}{\pi} \int_{\mathbb{R}} \frac{\alpha(\lambda)\,\mathrm{d}\lambda}{(\lambda - z_0)(\lambda - z)} \quad (\Im z, \Im z_0 > 0), \tag{4.49}$$

which allows us to determine $w(z)$ up to an additive constant if $\alpha(\lambda)$ is known.

Now we go deeper in the examination of the properties of the sets $\Sigma(L)$ and $R(L)$. In particular, we will retrieve some useful information about the existence of isolated eigenvalues for the full-line operator, as well for the half-line operators. We will prove that the assumptions on Ω and on the functions p, q, y ensure that the spectrum $\Sigma(L)$ of the family (SL_ω) has no isolated points. Moreover, at most one of the Weyl m-functions can have a pole in a given open interval $J \subset R(L)$; that is, if $J \subset R(L)$ is an open interval, then $m_+(\omega,\lambda)$ and $m_-(\omega,\lambda)$ have at most one pole $P(\omega) \in J$, and such a point $P(\omega)$ satisfies $\lim_{\varepsilon\to 0} |\Im m_+(\omega, P(\omega) + \mathrm{i}\varepsilon)| = \infty$ and $\lim_{\varepsilon \to 0} |m_-(\omega, P(\omega) + \mathrm{i}\varepsilon)| < \infty$, or vice-versa.

Let $\omega \in \Omega$, and define $\mathrm{RE}^{\pm}(L_\omega) = R^{\pm}(L_\omega) \cup \{\lambda \in \Sigma(L) \mid \lambda \text{is an isolated point}\}$. We begin with the following proposition, whose proof is straightforward.

PROPOSITION 4.28. *Let $\omega \in \Omega$. If $J \subset R(L)$ is any open interval, then both $m_+(\omega,\cdot)$ and $m_-(\omega,\cdot)$ extend meromorphically through J. In particular $m_\pm(\omega,\cdot)$ has a pole at every point $\lambda_0 \in J \cap \{\mathrm{RE}^{\pm}(L_\omega) \setminus R^{\pm}(L_\omega)\}$.*

REMARK 4.29. For every $\lambda \in J \subset R(L)$, $m_+(\omega,\lambda)$ and $m_-(\omega,\lambda)$ are elements of $\mathbb{P}(\mathbb{R})$. Moreover, the maps $\lambda \mapsto m_\pm(\omega,\lambda)$ rotate without rest in opposite directions in $\mathbb{P}(\mathbb{R})$ as λ increases in J. In particular, $m_+(\omega,\cdot)$ rotates counterclockwise, and $m_-(\omega,\cdot)$ rotates clockwise. In fact, this is a simple restatement of the following elementary facts: (i) for $\Im\lambda = 0$, $\mathrm{d}m_-/\mathrm{d}\lambda < 0$ if $m_- \neq \infty$, and $\mathrm{d}(1/m_-)/\mathrm{d}\lambda > 0$ for $m_- \neq 0$; (ii) for $\Im\lambda = 0$, $\mathrm{d}m_+/\mathrm{d}\lambda > 0$ if $m_+ \neq \infty$, and $\mathrm{d}(1/m_+)/\mathrm{d}\lambda < 0$ for $m_+ \neq 0$.

We now consider point (ii) of Theorem 4.21.

PROPOSITION 4.30. *The spectrum $\Sigma(L)$ of the family (SL_ω) does not contain any isolated point.*

PROOF. We argue by contradiction. Suppose that $\lambda_0 \in \Sigma(L)$ is an isolated point. Let $D \subset \mathbb{C}$ be a disc centered in λ_0 such that $D \cap \Sigma(L) = \{\lambda_0\}$. Then $D \subset \mathrm{RE}^{\pm}(L_\omega)$ for every $\omega \in \Omega$, and both $m_+(\omega, \cdot)$ and $m_-(\omega, \cdot)$ extend meromorphically through $D \cap \mathbb{R} = J$, for ν a.a. $\omega \in \Omega$. Set $m(\omega) = m_+(\omega, \lambda_0)$. Consider the set $C = \{\omega \in \Omega \mid L_\omega \text{has no eigenvalue at} \lambda_0\}$. We claim that C is closed. To prove the claim, we can argue as follows: first, we note that the set C is $\{\tau_t\}$-invariant. Let $\bar{\omega} \in C$, and let $\{t_n\} \subset \mathbb{R}$ be a sequence such that $t_n \to \infty$ as $n \to \infty$. Let $\omega_0 = \lim_{n\to\infty} \bar{\omega} \cdot t_n$. Let $P_n(\bar{\omega})$ denote the spectral matrix corresponding to $\bar{\omega} \cdot t_n$, for every $n \in \mathbb{N}$. Since λ_0 is an isolated point, then the trace $\operatorname{Tr} P_n(\bar{\omega})$ is constant in an open interval I_0 centered at λ_0, for every $n \in \mathbb{N}$. Since $\operatorname{Tr} P_n(\bar{\omega})$ weakly converges to $\operatorname{Tr} P(\omega_0)$, it follows that $\operatorname{Tr} P(\omega_0)$ is constant on I_0 as well, and hence $\omega_0 \in C$ (because the points of growth of $\operatorname{Tr} P(\omega_0)$ coincide with the points in the spectrum of the operator L_{ω_0}). We have proved the claim.

The complement set $\Omega_1 = \Omega \setminus C$ is open and dense, since, if $\omega \in \Omega_1$ has dense orbit (such a point exists, since ν is ergodic), then $\omega \cdot t \in \Omega_1$, for all $t \in \mathbb{R}$. Consider the function $h_n : \Omega \to \mathbb{P}(\mathbb{R}) : \omega \mapsto m_+(\omega, \lambda_0 + 1/n)$. It follows that $m(\omega) = \lim_{n\to\infty} h_n(\omega)$ is a pointwise limit of continuous functions, hence it has a residual set Ω_2 of continuity points. It is easy to check that Ω_2 is $\{\tau_t\}$-invariant. Let Ω_3 be the set of all $\omega \in \Omega$ with dense orbit in Ω. Then Ω_3 is a residual set as well. Choose a point $\bar{\omega} \in \Omega_1 \cap \Omega_2 \cap \Omega_3$. Then λ_0 is an isolated eigenvalue of $L_{\bar{\omega}}$, the function $m(\omega)$ is continuous at $\bar{\omega}$, and $\{\omega \cdot t \mid t \in \mathbb{R}\}$ is dense in Ω. Let Σ_1 be the closure of the set

$$\big\{(\bar{\omega} \cdot t, m(\bar{\omega} \cdot t)) \mid t \in \mathbb{R}\big\} \subset \Omega \times \mathbb{P}(\mathbb{R}) \subset \Omega \times \mathbb{P}(\mathbb{C}) = \Sigma.$$

As we already noted, the flow $(\Sigma, \{\hat{\tau}_t\})$ induces a flow $\{\hat{\tau}_t\}$ in $\Omega \times \mathbb{P}(\mathbb{R})$ (abusing the notation slightly). It follows that Σ_1 is compact and $\{\hat{\tau}_t\}$-invariant . Moreover, it is not difficult to show that Σ_1 contains a residual set of points $\sigma = (\omega, l)$ such that $\{\hat{\tau}_t(\sigma) \mid t \in \mathbb{R}\}$ is dense in Σ_1; in fact, Σ_1 is the α-limit set of the point $(\bar{\omega}, m(\bar{\omega}))$. Let $\sigma_0 = (\omega, l_0)$ be such a point. Let $\Sigma_2 = \Sigma_1 \cap \{\Omega_1 \times \mathbb{P}(\mathbb{R})\}$. Then Σ_2 is an open, dense and $\{\hat{\tau}_t\}$-invariant subset of Σ_1. Let $\sigma = (\omega, l) \in \Sigma_2$ and let $f_{\lambda_0}(\sigma)$ as in Eq. (4.36). Let u_0 be a vector of norm 1 which is contained in l. Then

$$\ln\big|u(t)\big| = \int_0^t f_{\lambda_0}\big(\hat{\tau}_s(\sigma)\big)\,\mathrm{d}s \to -\infty$$

as $t \to \pm\infty$. By the Baire category theorem, there exists an integer N and a set $\Sigma_3 \subset \Sigma_2$ such that for every $\sigma \in \Sigma_3$,

$$\int_0^t f_{\lambda_0}\bigl(\hat{\tau}(\sigma)\bigr)\,\mathrm{d}s \leqslant N$$

for every large $t \in \mathbb{R}$. But then $\hat{\tau}_t(\sigma_0) \in \Sigma_3$ for every large t, a contradiction. $\square$

The following result is of independent interest.

PROPOSITION 4.31. *For ν a.a $\omega \in \Omega$, the following relations hold*:

$$\mathrm{RE}^+(L_\omega) = \mathrm{RE}^-(L_\omega) = R(L) = R^{\mathrm{ed}}(L).$$

PROOF. According to Proposition 4.13, there is a set $\Omega_\nu \subset \Omega$ with $\nu(\Omega_\nu) = 1$ such that, if $\omega \in \Omega_\nu$, then ω has dense orbit and is positive and negative Poisson recurrent in the sense that there are sequences $\{t_n\} \to \infty$ and $\{s_n\} \to -\infty$ such that $\lim_{n\to\infty} \omega \cdot t_n = \lim_{n\to\infty} \omega \cdot s_n = \omega$.

Let $T > 0$, and consider Eq. (4.24_ω) on the interval $[0, T]$ together with the boundary conditions $\varphi(0) = \varphi(T) = 0$. There is a corresponding self-adjoint differential operator L_ω^T on the weighted space $L^2[0, T]$ with density $y(t)$. Let $J = (\lambda', \lambda'') \subset \mathbb{R}$ be an open interval containing exactly $k \geqslant 0$ eigenvalues of the half-line operator L_ω^+. We will use a beautiful argument of Hartman [66] to show that J contains no more than $k+1$ eigenvalues of L_ω^T.

To prove this statement, let $\varphi(t, \lambda_1), \ldots, \varphi(t, \lambda_k)$ be eigenfunctions of L_ω^+ corresponding to the eigenvalues $\lambda_1, \ldots, \lambda_k \in J$. Suppose for contradiction that L_ω^T admits $N \geqslant k+2$ eigenvalues in J with corresponding eigenfunctions $\varphi_1(t), \ldots, \varphi_N(t)$; thus $\varphi_j(0) = \varphi_j(T) = 0$ $(1 \leqslant j \leqslant N)$. Write

$$z(t) = \sum_{j=1}^N c_j \varphi_j(t) \quad (0 \leqslant t \leqslant T), \tag{4.50}$$

then determine coefficients $c_1, \ldots, c_N$, not all zero, such that

$$\begin{aligned} &z'(T) = 0,\\ &\int_0^T z(t)\varphi(t, \lambda_j) y(t)\,\mathrm{d}t = 0 \quad (1 \leqslant j \leqslant k). \end{aligned} \tag{4.51}$$

This is possible because $N \geqslant k+2$, while (4.51) consists of only $k+1$ linear relations.

Next extend $z(t)$ to all of $[0, \infty)$ by setting $z(t) = 0$ for $t \geqslant T$. Then z is in the domain of L_ω^+. Let $\bar{\lambda} = \frac{\lambda' + \lambda''}{2}$, and set $w = L_\omega^+(z) - \bar{\lambda} z$. Using (4.50) together with the spectral theorem for self-adjoint operators, we see that

$$\int_0^\infty w^2(t) y(t)\,\mathrm{d}t \geqslant \frac{(\lambda'' - \lambda')^2}{4} \int_0^\infty z^2(t) y(t)\,\mathrm{d}t.$$

On the other hand, condition (4.50) together with the fact that $L^T_\omega(z) = L^+_\omega(z)$ for $0 \leqslant t < T$ imply that

$$\int_0^\infty w^2(t)y(t)\,\mathrm{d}t = \int_0^T w^2(t)y(t)\,\mathrm{d}t < \frac{(\lambda'' - \lambda')^2}{4}\int_0^T z^2(t)y(t)\,\mathrm{d}t$$
$$= \frac{(\lambda'' - \lambda')^2}{4}\int_0^\infty z^2(t)y(t)\,\mathrm{d}t.$$

These relations are inconsistent, so $N \leqslant k + 1$ as stated.

Continuing, we claim that J contains no more than $2k + 2$ eigenvalues of $L^+_{\omega\cdot T}$. It is easiest to prove this by passing to the $u = \binom{u_1}{u_2}$-plane. The proof is by contradiction. Let $u(t,\lambda) = \binom{u_1(t,\lambda)}{u_2(t,\lambda)}$ satisfy (SL_ω) and $u_1(0,\lambda) = 0, u_2(0,\lambda) = 1$ ($\lambda \in J, 0 \leqslant t \leqslant T$). Furthermore, write $m(t,\lambda) = m_+(\omega\cdot t,\lambda)$ ($\lambda \in J, 0 \leqslant t \leqslant T$). Let us parametrize $u(t,\lambda)$ in a continuous way using the polar coordinate θ in the u-plane, then identify $u(t,\lambda)$ with its θ-value; we carry out the same operation on $m(t,\lambda)$ ($\lambda \in J, 0 \leqslant t \leqslant T$). It is clear that the interval $(m(T,\lambda'), m(T,\lambda''))$ contains $2k + 3$ consecutive numbers of the form $\frac{\pi}{2} + j\pi$, $j \in \mathbb{Z}$. A moment's thought shows that the interval $(u(T,\lambda'), u(T,\lambda''))$ contains $k+2$ consecutive numbers of the form $\frac{\pi}{2} + l\pi$, $l \in \mathbb{Z}$. But then L^T_ω has at least $k+2$ eigenvalues in J, contradicting the previous result. So in fact J contains non more than $2k + 2$ eigenvalues of $L^+_{\omega\cdot T}$, for each $T > 0$.

Now, let $\omega_1 \in \Omega$, and let $\{t_n\} \subset \mathbb{R}$ be a sequence of positive real numbers such that $\lim_{n\to\infty} \omega\cdot t_n = \omega_1$. Let $\rho^+_n := \rho^+_{\omega\cdot t_n}$ be the spectral measure corresponding to the half-line operator $L^+_{\omega\cdot t_n}$. Then ρ^+_n weakly converges to ρ^+, where ρ^+ is the spectral measure associated to $L^+_{\omega_1}$. The eigenvalues of $L^+_{\omega_1}$ correspond to the discontinuity points of ρ^+. It follows that ρ^+ has no more than $2k+3$ discontinuity points, because the previous remarks apply to each t_n.

Now, consider Eq. ($4.24_{\omega\cdot(-T)}$) in the interval $[0, T]$, together with the boundary conditions $u(0) = u(T) = 0$ ($T > 0$). It follows again that J contains no more than $2k + 3$ eigenvalues of the operator $L^+_{\omega\cdot(-T)}$. If we consider Eq. (4.24_ω) with the boundary conditions

$$u(0) = u(-T) = 0$$

then the number of eigenvalues in J of the operator L^{-T}_ω is equal to the number of eigenvalues, always in J, of the operator $L^T_{\omega\cdot(-T)}$, hence it is $\leqslant 2k + 3$.

Let $\{s_n\} \subset \mathbb{R}$ be a sequence of positive real numbers such that $\lim_{n\to\infty} \omega\cdot(-s_n) = \omega_1$. For every $n \in \mathbb{N}$, consider the spectral measure, which we still denote by ρ^+_n, corresponding to Eq. ($4.24_{\omega\cdot(-s_n)}$) in the interval $[-s_n, 0]$, together with the boundary conditions $u(0) = u(-s_n) = 0$. Recall that ρ^+_n is piecewise constant, with a jump of discontinuity equal to

$$\left(\int_{-s_n}^0 y(t)\left\|\chi_i(t)\right\|^2 \mathrm{d}t\right)^{-1}$$

at every eigenvalue λ_i of Eq. (4.24$_{\omega\cdot(-s_n)}$), where $\chi_i(t)$ is the normalized eigenfunction corresponding to the eigenvalue λ_i. It can be shown that ρ_n^+ converges weakly to $\rho_{\omega_1}^-$, where $\rho_{\omega_1}^-$ is the spectral measure for the negative half-line operator $L_{\omega_1}^-$. As before, we can prove that $\rho_{\omega_1}^-$ has at most $2k+3$ discontinuity points in J. We conclude that both $m_+(\omega,\cdot)$ and $m_-(\omega,\cdot)$ extend meromorphically through J. It follows that the spectral matrix M of the full line operator extends meromorphically through J, hence the full line operator L_ω has at most isolated eigenvalues on J. However, the spectrum of L_ω contains no isolated eigenvalues and in fact $R(L_\omega) = R(L)$, which in turn equals $R^{\mathrm{ed}}(L)$ by Proposition 4.15. All this implies that $R^+(L_\omega) \cup R^-(L_\omega) \subset R^{\mathrm{ed}}(L)$. Since $R^{\mathrm{ed}}(L) \subset R^+(L_\omega) \cup R^-(L_\omega)$, we have proved Proposition 4.31. □

Let us note that the statement of Proposition 4.31 holds on the orbit closure of any point ω which is positive and negative Poisson recurrent.

The final result concerning the structure of the spectrum is stated in the following

THEOREM 4.32. *Let $\omega \in \Omega$ have dense orbit, and let J be an open interval with $J \subset \mathrm{RE}^+(L_\omega)$. Then the half-line operator L_ω^+ has at most one eigenvalue in J. If L_ω^+ has an eigenvalue in J, then L_ω^- has no eigenvalue in J, and vice-versa. In particular, if $m_+(\omega,\cdot)$ has a pole $\lambda_0 \in J$, then λ_0 is a regular point for $m_-(\omega,\cdot)$ and vice-versa.*

PROOF. By some results of Coppel [29], the bundles Ker P_ω and Im P_ω vary continuously with respect to λ. Since $J \subset \mathrm{RE}^+(L_\omega)$, we have that $m_+(\omega,\lambda) \neq m_-(\omega,\lambda)$ for all $\lambda \in J$. Moreover, the above observations ensure that only one of $m_+(\omega,\cdot)$ and $m_-(\omega,\cdot)$ can attain the value ∞, and such a value can be attained at most once. This concludes the proof, since, from Theorem 4.11, $m_+(\omega,\cdot)$ and $m_-(\omega,\cdot)$ attain the values ∞ only at those points $\lambda \in J$ which are isolated eigenvalues for L_ω^+ and L_ω^- respectively. □

Our next goal is to complete the proof of point (iii) of Theorem 4.21. We need a formula for the z-derivative of $w(z)$ which involves the potential $y(\omega)$ and the Weyl m-functions as well. This formula will turn to be very useful also in the following, when we will discuss a theory of Kotani-type for the general Sturm–Liouville operator. In [59,31,89], and also in [81], one can find very interesting (trace) formulas for $\mathrm{d}w/\mathrm{d}z$ and its representation in terms of the trace of the spectral matrix $P(\lambda)$ arising from the Green (matrix) function. In our case, it is not very difficult to compute directly such a derivative. Let $\mathcal{L} = \{f : \Omega \to \mathbb{R} \mid f \text{ is continuous and strictly positive}\}$. Then $\mathcal{L}$ can be regarded as an open subset of the Banach space $C(\Omega)$ of continuous real-valued functions on Ω. By a direct observation of the Riccati equation (4.25), letting $\tilde{z} = zy$, the Floquet exponent $w(\cdot)$ can be considered as a functional from $\mathcal{L}$ into $\mathbb{C}$, as follows: $w(z,\cdot) : \mathcal{L} \to \mathbb{C} : y \mapsto w(zy)$, for each fixed $z \in \mathbb{C}$. We now adapt to our Sturm–Liouville setting the developments in [89].

PROPOSITION 4.33. *For every fixed $z \in \mathbb{C} \setminus \mathbb{R}$, the functional $w(z,\cdot)$ defined above admits a Frechet derivative $D_f w(z,\cdot)$ along every direction $f \in \mathcal{L}$. Moreover, for every $z \in \mathbb{C}$ with $\Im z \neq 0$, and for every ergodic measure ν on Ω, we have*

$$\frac{\mathrm{d}}{\mathrm{d}z} w(z) = \int_\Omega \frac{y(\omega)}{m_-(\omega,z) - m_+(\omega,z)} \,\mathrm{d}\nu(\omega). \tag{4.52}$$

PROOF. Let $z \in \mathbb{C} \setminus \mathbb{R}$. Consider the functionals $m_\pm : \mathcal{L} \to \mathbb{C} : y \mapsto m_\pm(z, y)$, and suppose for the moment that $m_\pm$ are Frechet differentiable at $y \in \mathcal{L}$. Let $f \in \mathcal{L}$ and denote by $D_f m_\pm(z, y)$ the Frechet derivatives of $m_\pm(z, \cdot)$ computed at $y \in \mathcal{L}$ in the direction $f \in \mathcal{L}$. Then we have

$$D_f w(z, y) = \int_\Omega \frac{D_f m_+(z, y(\omega)) - D_f m_-(z, y(\omega))}{2p(\omega)} \, \mathrm{d}\nu, \tag{4.53}$$

where ν is a fixed ergodic measure on Ω. This shows that w is Frechet differentiable at $y \in \mathcal{L}$.

We compute $D_f m_\pm(z, y)$. From the Riccati equation (4.25) it follows that $D_f m_\pm(z, y)$ must satisfy

$$\big(D_f m_\pm(z, y)\big)' + \frac{2}{p} m_\pm D_f m_\pm(z, y) = -zf. \tag{4.54}$$

The solutions $\hat{D}_f m_\pm(z, y)$ of these first order differential equations are

$$\begin{aligned} \hat{D}_f m_-(z, y) &= \int_{-\infty}^{t} -zf(s) \exp\left\{2 \int_t^s \frac{m_-}{p} \, \mathrm{d}r\right\} \mathrm{d}s, \\ \hat{D}_f m_+(z, y) &= \int_t^{\infty} zf(s) \exp\left\{2 \int_t^s \frac{m_+}{p} \, \mathrm{d}r\right\} \mathrm{d}s \end{aligned} \tag{4.55}$$

hence

$$\hat{D}_f m_-(z, y) = \int_{-\infty}^{t} -zf(s) \frac{\varphi_-^2(s)}{\varphi_-^2(t)} \, \mathrm{d}s \tag{4.56}$$

and

$$\hat{D}_f m_+(z, y) = \int_t^{\infty} zf(s) \frac{\varphi_+^2(s)}{\varphi_+^2(t)} \, \mathrm{d}s. \tag{4.57}$$

Now we show that $D_f m_\pm(z, y)$ actually exist and equal the solutions $\hat{D}_f m_\pm(z, y)$ defined in (4.56) and (4.57). We prove this only for m_+. Let us simplify the notation and omit the dependence with respect to $z \in \mathbb{C} \setminus \mathbb{R}$. Let $\Delta m_+ = m_+(y + \varepsilon f) - m_+(y)$. Then the Riccati equation (4.25) ensures that

$$(\Delta m_+)' + \frac{1}{p}\big(m_+(y + \varepsilon f) + m_+(y)\big)\Delta m_+ = -z\varepsilon f. \tag{4.58}$$

Since $\Im z \neq 0$, the family (SL_ω) admits an exponential dichotomy, and an estimate of Coppel ([29], page 34) ensures that $m_+(y + \varepsilon f) = m_+(y) + \mathcal{O}(\varepsilon f)$. It follows that Eq. (4.58) admits a unique bounded solution which (obviously) must be Δm_+. Moreover

$$\Delta m_+(t) = \int_t^{\infty} z\varepsilon f(s) \exp\left\{\int_t^s \frac{2m_+(y) + \mathcal{O}(\varepsilon f)}{p} \, \mathrm{d}r\right\} \mathrm{d}s.$$

It is now easy to see that

$$\lim_{\varepsilon\to 0}\frac{|\Delta m_+ - \varepsilon\hat{D}_f m_+(z,y)|}{\varepsilon}=0,$$

where the limit is appropriately uniform in $f\in\mathcal{L}$. This shows that $D_f m_+(z,y)$ exists and equals $\hat{D}_f m_+(z,y)$ for every $f\in\mathcal{L}$. The same holds for m_-.

It remains to prove the formula (4.52). Let us consider the Frechet derivatives $D_y m_\pm(z,y)$ along the direction y. By a direct computation, we get

$$\begin{aligned}D_y w(z,y)&=\lim_{\varepsilon\to 0}\frac{w(z(y+\varepsilon y))-w(zy)}{\varepsilon}=\lim_{\varepsilon\to 0}\frac{w(zy(1+\varepsilon))-w(zy)}{\varepsilon}\\&=z\frac{\mathrm{d}}{\mathrm{d}z}w(z,y).\end{aligned}$$

We calculate $D_y w(z,y)$: we have

$$\begin{aligned}&\frac{D_y m_+(z,y)-D_y m_-(z,y)}{p}\\&\quad=\frac{z}{p}\left[\left(\int_t^\infty\frac{\varphi_+^2(s)}{\varphi_+^2(t)}y(s)\,\mathrm{d}s+\int_{-\infty}^t\frac{\varphi_-^2(s)}{\varphi_-^2(t)}y(s)\,\mathrm{d}s\right)\right].\end{aligned}\tag{4.59}$$

Next we observe that

$$\left(\frac{\varphi_+}{\varphi_-}\right)'=\frac{\varphi_+'\varphi_- - \varphi_+\varphi_-'}{\varphi_-^2}=-\frac{W}{p\varphi_-^2}\quad\text{and}\quad\left(\frac{\varphi_-}{\varphi_+}\right)'=\frac{\varphi_-'\varphi_+ - \varphi_-\varphi_+'}{\varphi_+^2}=\frac{W}{p\varphi_+^2}$$

where W is the Wronskian of φ_+ and φ_-. We obtain

$$\begin{aligned}&\frac{D_y m_+(z,y)-D_y m_-(z,y)}{2p}\\&\quad=\frac{z}{2W}\left[\left(\frac{\varphi_-}{\varphi_+}\right)'\int_t^\infty\varphi_+^2(s)y(s)\,\mathrm{d}s-\left(\frac{\varphi_+}{\varphi_-}\right)'\int_{-\infty}^t\varphi_-^2(s)y(s)\,\mathrm{d}s\right].\end{aligned}\tag{4.60}$$

It follows that

$$\begin{aligned}D_y w(z,y)=\lim_{T\to\infty}\frac{1}{T}\int_0^T\frac{z}{2W}\bigg[&\left(\frac{\varphi_-}{\varphi_+}\right)'\int_t^\infty\varphi_+^2(s)y(s)\,\mathrm{d}s\\&-\left(\frac{\varphi_+}{\varphi_-}\right)'\int_{-\infty}^t\varphi_-^2(s)y(s)\,\mathrm{d}s\bigg]\mathrm{d}t.\end{aligned}\tag{4.61}$$

To make the computation easier, we add in the integral the derivative with respect to t of the function

$$h(t)=\frac{z}{2W}\left[\left(-\frac{\varphi_-}{\varphi_+}\right)\int_t^\infty \varphi_+^2(s)y(s)\,\mathrm{d}s+\left(\frac{\varphi_+}{\varphi_-}\right)\int_{-\infty}^t \varphi_-^2(s)y(s)\,\mathrm{d}s\right]. \tag{4.62}$$

Note that $h'(t)$ gives no contribution to the integral (4.61). We obtain

$$\begin{aligned}&\lim_{T\to\infty}\frac{z}{T}\int_0^T\frac{1}{2W}\left[\left(\frac{\varphi_-}{\varphi_+}\right)'\int_t^\infty \varphi_+^2(s)y(s)\,\mathrm{d}s-\left(\frac{\varphi_+}{\varphi_-}\right)'\int_{-\infty}^t \varphi_-^2(s)\,\mathrm{d}s\right]\mathrm{d}t\\ &\quad=\lim_{T\to\infty}\frac{z}{T}\int_0^T\frac{1}{2W}\left[\left(\frac{\varphi_-}{\varphi_+}\right)'\int_t^\infty \varphi_+^2(s)y(s)\,\mathrm{d}s\right.\\ &\qquad\left.-\left(\frac{\varphi_+}{\varphi_-}\right)'\int_{-\infty}^t \varphi_-^2(s)y(s)\,\mathrm{d}s+h'(s)\right]\mathrm{d}t\\ &\quad=\lim_{T\to\infty}\frac{z}{T}\int_0^T\frac{y(t)(\varphi_+(t)+\varphi_-(t))}{2(m_-(\omega\cdot t,z)-m_+(\omega\cdot t,z))}\,\mathrm{d}t.\end{aligned} \tag{4.63}$$

Using the Birkhoff ergodic theorem we have

$$\frac{\mathrm{d}w}{\mathrm{d}z}=\int_\Omega\frac{y(\omega)(\varphi_+(0)+\varphi_-(0))}{2(m_-(\omega,z)-m_+(\omega,z))}\,\mathrm{d}\nu(\omega)=\int_\Omega\frac{y(\omega)}{m_-(\omega,z)-m_+(\omega,z)}\,\mathrm{d}\nu(\omega)$$

for every $\{\tau_t\}$-ergodic measure ν on Ω. The proof is complete. □

We can now return to point (iii) of Theorem 4.21. Arguing as in [89, Section 6], and using our formula (4.52) for $\frac{\mathrm{d}w}{\mathrm{d}z}$ together with (4.49), we can show that, if $\alpha(\lambda)$ is constant in an interval $I\subset\mathbb{R}$, then $I\subset R(L)$. We omit the details as they are similar to those in the cited paper [89].

In the rest of Section 4.3 we discuss a theory of Kotani-type for the Sturm–Liouville operator. We begin with the following lemmas.

LEMMA 4.34. *If* $\Im z\neq 0$, *then*

$$\Re w(z)=\mp\frac{\Im z}{2}\int_\Omega\frac{y(\omega)}{\Im m_\pm(\omega,z)}\,\mathrm{d}\nu. \tag{4.64}$$

In particular,

$$\Re w(z)\leqslant 0.$$

PROOF. We consider the imaginary parts in the Riccati equation for m_+, obtaining

$$\Im m_+'+\frac{2}{p}\Re m_+\Im m_+=-y\Im z.$$

Now, dividing by $\Im m_+$ on both sides of the equation, we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\ln(\Im m_+) + \frac{2}{p}\Re m_+ = -\frac{y\Im z}{\Im m_+},$$

and hence the proof follows integrating both sides on Ω with respect to the ergodic measure ν, and using the Birkhoff ergodic theorem. □

Let us denote by $H^\pm$ the upper and lower complex half-planes respectively.

LEMMA 4.35. *Let $I \subset \mathbb{R}$ be an open interval and let $f : H^+ \to H^+$ be analytic.*

Suppose that $\lim_{\varepsilon\to 0^+}\Re(f(\lambda + \mathrm{i}\varepsilon)) = 0$ *for Lebesgue a.a. $\lambda \in I$. Then f extends analytically through I, and its extension $\bar{f}$ has positive imaginary part on I.*

Lemma 4.35 is a standard result from the theory of complex functions, hence we will not give the proof. Instead we refer to a standard text such as [64] for more details.

Recall that $\lim_{\varepsilon\to 0}\Re w(\lambda + \mathrm{i}\varepsilon) = \beta(\lambda)$ and $\lim_{\varepsilon\to 0}\Im w(\lambda + \mathrm{i}\varepsilon) = \alpha(\lambda)$, for every $\lambda \in \mathbb{R}$. Motivated by Kotani's seminal work on the Schrödinger operator [101], and using the above formulas (4.64) and (4.52), we obtain, after omitting to write the dependence with respect to z of the functions involved:

$$\begin{aligned}
&-4\left(\frac{\Re w}{\Im z} + \Im\frac{\mathrm{d}w}{\mathrm{d}z}\right) \\
&\quad = \int_\Omega \frac{y(\omega)(\Im m_-(\omega) - \Im m_+(\omega))}{\Im m_-(\omega)\Im m_+(\omega)}\left(1 + 4\frac{\Im m_-(\omega)\Im m_+(\omega)}{|m_-(\omega) - m_+(\omega)|^2}\right)\mathrm{d}\nu \\
&\quad = \int_\Omega y(\omega)\left(\frac{1}{\Im m_+(\omega)} - \frac{1}{\Im m_-(\omega)}\right) \\
&\qquad \times \left(\frac{[\Re(m_-(\omega) - m_+(\omega))]^2 + [\Im(m_-(\omega) + m_+(\omega))]^2}{|m_-(\omega) - m_+(\omega)|^2}\right)\mathrm{d}\nu.
\end{aligned}$$

Let $I \subset \mathbb{R}$ be an open interval such that $\beta(\lambda) = 0$ for Lebesgue a.a. $\lambda \in I$. Note that the function $-w(\cdot)$ is analytic in the upper half-plane H^+ and has positive real part there. In addition $-w(\cdot)$ is bounded in every compact subset of H^+. We apply the Schwarz reflection principle [136], to prove that $w(\cdot)$ admits an analytic extension from H^+ through I to the set $H = I \cup \{\lambda \in \mathbb{C} \mid \Im\lambda \neq 0\}$. Since $\beta(\lambda) = 0$ for Lebesgue a.a. $\lambda \in I$, we have $\Re w(\lambda) = 0$. It follows that

$$\Im\frac{\mathrm{d}w}{\mathrm{d}\lambda}(\lambda) = -\lim_{\varepsilon\to 0^+}\frac{\Re w(\lambda + \mathrm{i}\varepsilon)}{\varepsilon}.$$

Since the limits $\lim_{\varepsilon\to 0^+} m_\pm(\omega, \lambda + \mathrm{i}\varepsilon) := m_\pm(\omega, \lambda)$ exist for Lebesgue a.a. $\lambda \in I$ and for ν a.a. $\omega \in \Omega$, we can use Fatou's Lemma and the computation above to obtain that $\Re m_+(\omega, \lambda) = \Re m_-(\omega, \lambda)$ and $\Im m_+(\omega, \lambda) = -\Im m_-(\omega, \lambda)$, for Lebesgue a.a. $\lambda \in I$ and for ν a.a. $\omega \in \Omega$. We claim that the maps $(m_+ - m_-)(\omega, \cdot)$ and $\frac{m_- m_+}{m_- - m_+}(\omega, \cdot)$ extend analytically through I to H. To prove the claim, we first describe a general fact concerning functions which are analytic in H^+. Let $f(z)$ be an analytic function on H^+ with $\Im f(z) > 0$ for all $z \in H^+$. Put

$$F(z) = \ln f(z) = \ln\bigl|f(z)\bigr| + \mathrm{i} \arg f(z) = u(z) + \mathrm{i} v(z),$$

where $0 \leqslant \arg f(z) < \pi$. It follows that $u(z)$ is harmonic in H^+, and that $v(z)$ is harmonic and bounded in H^+. For $F(z)$ a generalized version of the Schwarz reflection principle holds [64]: namely, if $\Im F(\lambda) = 0$ for Lebesgue a.a $\lambda \in I$, then $F(z)$ extends analytically through I from $H \cap H^+$ to $H \cap H^-$. In our case, it follows that for ν-a.a $\omega \in \Omega$, the function $m(\omega, \cdot) := m_+(\omega, \cdot) - m_-(\omega, \cdot)$ has the properties that $\Im m(\omega, z) > 0$, for every $z \in H^+$, $\Re m(\omega, \lambda) = 0$ and $\Im m_+(\omega, \lambda) = -\Im m_-(\omega, \lambda)$, for Lebesgue a.a $\lambda \in I$. Letting $G(z) = \ln m(\omega, z)$, we have $G(z) = \ln|m(\omega, z)| + i\pi/2$. The function $F(z) = G(z) - \mathrm{i}\pi/2$ satisfies $\Im F(\lambda) = 0$ for Lebesgue a.a. $\lambda \in I$. From the above observations, it follows that $m_+(\omega, z) - m_-(\omega, z)$ extends analytically through I to H^-. The same holds for the function $\frac{m_- m_+}{m_- - m_+}$. Now, it is easy to prove that both m_+ and m_- extend analytically through I from $H \cap H^+$ to $H \cap H^-$. We proved the first part of the following important

THEOREM 4.36. *Let $I \subset \mathbb{R}$ be an open interval, and suppose that $\beta(\lambda) = 0$ for Lebesgue a.a. $\lambda \in I$. Then, for ν a.a. $\omega \in \Omega$, the Weyl m-functions $m_\pm(\omega, \cdot)$ admit analytic extensions through I from H^+ to H^-. If we denote these extensions with $h_\pm(\omega, \cdot)$, then*

$$h_+(\omega, \lambda) = \begin{cases} m_+(\omega, \lambda), & \Im\lambda > 0, \\ m_-(\omega, \lambda), & \Im\lambda < 0 \end{cases} \quad \textit{and} \quad h_-(\omega, \lambda) + \begin{cases} m_-(\omega, \lambda), & \Im\lambda > 0, \\ m_+(\omega, \lambda), & \Im\lambda < 0. \end{cases}$$

PROOF. We give the proof only for $h_+(\omega, \cdot)$. Let $\Omega_1 \subset \Omega$ such that both m_+ and m_- extend analytically through I. Let $\Omega_2 \subset \Omega$ be the set consisting on those points $\omega \in \Omega$ with dense orbit. Then $\nu(\Omega_1 \cap \Omega_2) = 1$. Choose $\bar{\omega} \in \Omega_1 \cap \Omega_2$. Let $\lambda \in \mathbb{C}$ with $\Im\lambda \neq 0$, and define $h_+(\lambda) := h_+(\bar{\omega}, \lambda)$. We write down the Riccati equation (4.25)

$$m' + \frac{1}{p} m^2 = q - \lambda y.$$

Suppose that $\Im\lambda < 0$. Then, for every initial condition $m_0 \in \mathbb{R}$ and for every $t > 0$, we have $\Im m(t, \lambda) > 0$ and $\Im n(t, \lambda) := \Im \frac{1}{m(t, \lambda)} < 0$, where $m(t, \lambda)$ is the solution of Eq. (4.25) satisfying $m(0, \lambda) = m_0 \in \mathbb{R}$. We define a flow $\{\tilde{\tau}_t\}$ on $\Omega \times \mathbb{P}(\mathbb{C}) = \Sigma$ by setting

$$\tilde{\tau}_t(\omega, m) = \bigl(\omega \cdot t, m(t)\bigr),$$

where $m(t)$ is the solution of Eq. (4.25) satisfying $m(0) = m \in \mathbb{C}$. Note that the flow $\{\tilde{\tau}_t\}$ can be defined in an equivalent manner by considering the action of the flow $\{\hat{\tau}_t\}$ on complex lines in $\mathbb{P}(\mathbb{C})$, i.e.,

$$\tilde{\tau}_t(\omega, m) = \hat{\tau}_t\left(\omega, \begin{pmatrix} 1 \\ m \end{pmatrix}\right).$$

From the above observations, it follows easily that for every fixed $\omega \in \Omega$, $\lambda \in H^-$ and $t > 0$, the map $\tilde{\tau}_t^\omega : \mathbb{P}(\mathbb{C}) \to \mathbb{P}(\mathbb{C}) : m \mapsto \tilde{\tau}_t(\omega, m) = (\omega \cdot t, m(t))$ maps the closure of the set $\{\infty\} \times \{z \in \mathbb{C} \mid \Im z \geqslant 0\}$ into H^+. Alternatively, identifying H^+ with a disc B contained in $\mathbb{P}(\mathbb{C})$, $\tilde{\tau}_t^\omega$ maps the closure of B into B, for every $\omega \in \Omega$, $\lambda \in H^-$ and $t > 0$.

These things being said, let $S^\pm(\lambda) = \{(\omega, m_\pm(\omega, \lambda)) \mid a \in \Omega\} \subset \Sigma$. Then $S^\pm(\lambda)$ are $\{\tilde{\tau}_t\}$-invariant sections of Σ. Recall that $S^\pm(\lambda)$ are minimal subsets of the projective flow $(\Sigma, \{\hat{\tau}_t\})$.

We claim that $S^\pm(\lambda)$ are the only $\{\tilde{\tau}_t\}$-invariant sections of Σ. To prove this, we use methods already exploited in Section 3. Suppose for contradiction that S is another invariant section of Σ. Let $\omega \in \Omega$ have dense orbit. Then there exists $l \in \mathbb{P}(\mathbb{C})$ such that $(\omega, l) \in S$. It follows that $(\omega, m_+(\omega, \lambda))$, $(\omega, m_-(\omega, \lambda))$ and (ω, l) form distal pairs in Σ. Choose unit vectors $u^+ \in m_+(\omega, \lambda)$, $u^- \in m_-(\omega, \lambda)$, $u \in (\omega, l)$. Then u^+, u^-, u are pairwise linearly independent. Let $\Phi_\omega(t)$ be the fundamental matrix solution of Eq. (SL_ω) with $\Phi_\omega(0) = I$. Let $u^\pm(t) = \Phi_\omega(t) u^\pm$, $u(t) = \Phi_\omega(t) u$. Since $\Im\lambda \neq 0$, the family (SL_ω) admits an exponential dichotomy over Ω, hence for every fixed $\omega \in \Omega$,

$$\lim_{t \to -\infty} \left|u^+(t)\right| = \infty, \qquad \lim_{t \to \infty} \left|u^-(t)\right| = \infty.$$

Suppose that $u(t)$ is unbounded at ∞. Let $\Psi(t)$ be the fundamental matrix solution of Eq. (SL_ω) whose columns are $u^-(t)$ and $u(t)$. By Liouville's formula, $\det \Psi(t) = \det \Psi(0) = \mathit{const} \neq 0$, and since $u^-(t)$ is unbounded at ∞, we must have $|u(t)| \to 0$, a contradiction. Hence $u(t)$ is bounded at ∞. We carry out the same reasoning at $-\infty$ to prove that $u(t)$ decays as $|t| \to \infty$. However, in this case, let $\Psi_1(t)$ be the fundamental matrix solution of Eq. (SL_ω) whose columns are $u^+(t)$ and $u(t)$. Then $\liminf_{t \to \infty} \det \Psi_1(t) = 0$, a contradiction. We proved that $S^\pm(\lambda)$ are the unique $\{\tilde{\tau}_t\}$-invariant minimal sections of Σ.

Now, let D_0 be a complex domain with $D_0 \supset (I \cup \{\lambda \mid \Im\lambda \neq 0\})$ and such that $h_+(\lambda)$ is analytic and has positive imaginary part in D_0. For every $t > 0$, we define a function $g_t : D_0 \to \mathbb{C}$, by setting

$$\bigl(\tilde{\tau}_t(\bar{\omega}), g_t(\lambda)\bigr) = \tilde{\tau}_t\bigl(\bar{\omega}, h_+(\lambda)\bigr),$$

i.e., $g_t(\lambda) = h_+(t, \lambda)$, where $h_+(t, \lambda)$ is the solution of Eq. (4.25) satisfying $h_+(0, \lambda) = h_+(\lambda)$. It follows that, for every $t > 0$, g_t maps D_0 into H^+. In fact, if $\Im\lambda > 0$, this follows from the invariance of the section $S^+(\lambda)$; if $\lambda \in I$, it follows from $\Im h_+ > 0$, and if $\Im\lambda < 0$, it follows from $\Im h_+ > 0$ and the first part of the proof. Moreover, for every $t > 0$, the map g_t in analytic in D_0, since $g_t(\lambda) = h_+(t, \lambda) = \Phi_{\bar{\omega}}(t)\binom{1}{h_+(\lambda)}$ and $\Phi_{\bar{\omega}}(t)$ is linear. It follows that the family $\{g_t(\lambda), t > 0\}$ is a normal family. Let $\omega \in \Omega$, and choose a sequence $\{t_n\} \to \infty$ such that $\bar{\omega} \cdot t_n \to \omega$ and such that $g_{t_n}(\lambda)$ converges to a holomorphic function $g_\omega(\lambda)$ on compact subsets of D_0 (if necessary, we pass to a subsequence). From the invariance and the continuity of the section $S^+(\lambda)$ with respect to λ, we conclude that $g_\omega(\lambda) = m_+(\omega, \lambda)$ for every λ with $\Im\lambda > 0$. Moreover, one easily sees that $g_{t_n}(\lambda)$ converges to $g_\omega(\lambda)$ on compact subsets of D_0, for every sequence $\{t_n\} \subset \mathbb{R}$ such that $\bar{\omega} \cdot t_n \to \omega$ as $n \to \infty$.

We can repeat this construction for every $\omega \in \Omega$. Now, using standard arguments about normal families [37], we prove that the section $S(\lambda) = \{(\omega, g_\omega(\lambda)) \mid \omega \in \Omega\}$ is continuous and $\{\tilde{\tau}_t\}$-invariant for every $\lambda \in \mathbb{C}$ with $\Im\lambda > 0$. Of course $S(\lambda) = S^-(\lambda)$ if $\Im\lambda < 0$, and the proof is complete (for m_- we use similar arguments). $\square$

We summarize the results we obtained about the behavior of the Weyl m-functions when crossing the real line, in the following

THEOREM 4.37. *For ν a.a. $\omega \in \Omega$, the Weyl m-functions extend meromorphically through every interval $J \subset R(L)$ from H^+ to H^-. Moreover, $m_\pm(\omega,\lambda) \in \mathbb{P}(\mathbb{R})$, for all $\lambda \in J$.*

If $I \subset \mathbb{R}$ is an open interval such that $\beta(\lambda) = 0$ for Lebesgue a.a. $\lambda \in I$, then $m_\pm$ extend analytically through I from H^+ to H^-. The extensions $h_\pm(\omega,\cdot)$ satisfy $h_\pm(\omega,z) = m_\mp(\omega,z)$ for all $z \in H^-$, and $\Re h_+(\omega,\lambda) = \Re h_-(\omega,\lambda)$ for Lebesgue a.a. $\lambda \in I$.

We finish this subsection by observing that actually $\beta(\lambda)$ can attain the value 0 only at points $\lambda \in \Sigma(L)$. In fact, if $\lambda \in R(L)$, it is a simple consequence of the Oseledets theorem that $\beta(\lambda) < 0$ (the Oseledets bundles are disjoint, and are contained in the bundles of exponential dichotomy, hence there are exactly two Lyapunov exponents, $\beta_1(\lambda) = -\beta_2(\lambda) \neq 0$).

4.4. *The inversion problem*

In this part, we pose and solve our inverse algebro-geometric problem for the Sturm–Liouville operator. We impose the following basic

HYPOTHESIS 4.38.

(H1) The spectrum of the family (SL_ω) is a finite union of closed intervals: $\Sigma(L) = [\lambda_0,\lambda_1] \cup [\lambda_2,\lambda_3] \cup \cdots \cup [\lambda_{2g},\infty)$ $(\lambda_0 > 0)$.

(H2) The Lyapunov exponent vanishes almost everywhere in the spectrum: $\beta(\lambda) = 0$ for Lebesgue a.a. $\lambda \in \Sigma(L)$.

We claim that the hypothesis that $\lambda_0 > 0$ is not restrictive, i.e., that if $\lambda_0 \leqslant 0$, then we can "translate" Eqs. (SL_ω) in such a way that the translated spectrum has $\tilde{\lambda}_0 > 0$, without any loss of regularity of the functions involved. For, suppose that $\lambda_0 \leqslant 0$, and choose $\eta > 0$. It is easy to check that the "translated" family of equations

$$(p\varphi')' - \big[q - (\lambda_0 - \eta)y\big]\varphi = -\lambda y\varphi \qquad (5.2^\eta_\omega)$$

has a spectrum Σ_η which equals the set $\Sigma(L) - \lambda_0 + \eta$. Moreover, the family (5.2^η_ω) satisfies Hypotheses 4.38. See ([95], Section 4) for more details concerning this fact.

Let $\mathcal{R}$ be the Riemann surface of the algebraic relation

$$w^2 = -(\lambda - \lambda_0)(\lambda - \lambda_1)\cdots(\lambda - \lambda_{2g}).$$

The surface $\mathcal{R}$ can be viewed as the union of two copies of the Riemann sphere $\mathbb{C} \cup \{\infty\}$ cut open along $\Sigma(L)$ and glued together in the standard way. Alternatively, $\mathcal{R}$ can be viewed as an analytic g torus, with holes obtained by cutting the Riemann sphere along (closed) paths c_i issuing from λ_{2i-1} $(i = 1, \dots, g)$ such that $\lambda_{2i} \in c_i$ for all $i = 1, \dots, g$. Let $\pi : \mathcal{R} \to \mathbb{C} \cup \{\infty\}$ be the projection of $\mathcal{R}$ to the Riemann sphere. Then π is 2-1 except at the ramification (or branch) points $\{\lambda_0, \lambda_1, \dots, \lambda_{2g}, \infty\}$, where it is 1-1. We abuse notation slightly, and write $\lambda_1, \lambda_2, \dots, \lambda_{2g}, \infty \in \mathcal{R}$. Let $\pi^{-1}(0) = \{0^+, 0^-\}$. Define a meromorphic function k on $\mathcal{R}$ by letting $k(0^+)$ be the positive square root of $\prod_{i=0}^{2g} \lambda_i$ and letting $k(P)$ be the appropriate square root of $-\prod_{i=0}^{2g}(\pi(P) - \lambda_i)$ for each $P \in \mathcal{R}$.

Let $\omega \in \Omega$, and define a function M_ω on $\mathcal{R} \setminus \{\lambda_0, \lambda_1, \dots, \lambda_{2g}\}$ as follows: put $M_\omega(0^+) = m_+(\omega, 0)$, $M_\omega(0^-) = m_-(\omega, 0)$. We define $M_\omega(P)$ by continuation along a curve in $\mathcal{R}$ joining 0^+ to P, for each $P \in \mathcal{R}$. Theorem 4.37 ensures that the function M_ω on $\mathcal{R} \setminus \{\lambda_0, \lambda_1, \dots, \lambda_{2g}\}$ defined in this way is meromorphic in a neighborhood of every point $P \in \mathcal{R}$ which is not a ramification point of $\mathcal{R}$.

Let us prove the following important

THEOREM 4.39. *Suppose that Hypotheses* (H1) *and* (H2) *hold, and let* $\omega \in \Omega$. *Then* $m_+(\omega, \cdot)$ *and* $m_-(\omega, \cdot)$ *define a single meromorphic function* $M_\omega : \mathcal{R} \to \mathbb{C} \cup \{\infty\}$. *Moreover, the map* $M : \Omega \times \mathcal{R} \to \mathbb{C} \cup \{\infty\} : (\omega, P) \mapsto M_\omega(P)$ *is jointly continuous.*

PROOF. To extend M_ω to a meromorphic function defined on all $\mathcal{R}$, we examine the behavior of the Weyl m-functions near a ramification point $\{\lambda_0, \lambda_1, \dots, \lambda_{2g}, \infty\}$. So, let $\lambda_* \in \{\lambda_0, \lambda_1, \dots, \lambda_{2g}\}$. Let $\omega \in \Omega$, and let $D_* \subset \mathbb{C}$ be a punctured disc centered at λ_* such that D_* has diameter equal to the union of an interval $I_* \subset \mathbb{R} \setminus \Sigma(L)$ and an interval contained in $\Sigma(L)$. If $m_+(\omega, \cdot)$ is continued around a circle in D_* centered in λ_*, it goes into $m_-(\omega, \cdot)$, and vice-versa. If we introduce the coordinate $z = \sqrt{\lambda - \lambda_*}$, then the inverse image of D_* in the z-plane is a punctured disc $D_\#$ centered at $z = 0$, and $m_\pm(\omega, \cdot)$ are branches of a meromorphic function M_ω in $D_\#$. Shrinking the disc $D_\#$ if necessary, we see that M_ω omits infinitely many (real) values in $D_\#$. By the Picard theorem [64], M_ω is meromorphic on the full disc $D_\# \cup \{0\}$. For the ramification point ∞, let D_∞ be a disc in the Riemann sphere centered at ∞ such that $D_\infty \cap \mathbb{R} \subset (-\infty, \lambda_0) \cup (\lambda_{2g}, \infty)$. Arguing as above, we observe that M_ω omits infinitely many real values in the punctured disc $\pi^{-1}(D_\infty)$, and applying the Picard theorem again, we conclude that M_ω extends meromorphically at ∞. Moreover, the bundles $\operatorname{Im} P_\omega$ and $\operatorname{Ker} P_\omega$ of the exponential dichotomy vary continuously with respect to $\omega \in \Omega$, ensuring that the map $M : \Omega \times \mathcal{R} \to \mathbb{C} \cup \{\infty\}$ is jointly continuous. ☐

Let $(\Omega, \{\tau_t\})$ be a topological flow, and let ν be a $\{\tau_t\}$-ergodic measure on Ω. We suppose that the topological support of ν equals Ω. Let p, q, and $y : \Omega \to \mathbb{R}$ be continuous functions such that p and y assume only positive values. We assume that the derivative $\omega \mapsto \frac{\mathrm{d}}{\mathrm{d}t} p(\omega \cdot t)|_{t=0}$ exists and is continuous. Again a word concerning the way we let the functions involved vary with $t \in \mathbb{R}$: if we fix $\omega \in \Omega$, we can consider p, q, y as functions of t: for instance, $p(t)$ is identified with $p(\omega \cdot t)$, and similarly for q, y. Suppose that Hypotheses 4.38 hold for these data.

Our goal is to determine all such functions p, q, y. Some of the following material follows closely the exposition in a recent paper in the journal Discrete and Continuous Dynamical Systems A **18**; see reference [96] below. We thank the editor Prof. Shouchuan Hu of that journal for permission to present this material here. Let $\omega \in \Omega$, $\lambda \in \mathbb{C} \setminus \Sigma(L)$, and let $m_\pm(t) = m_\pm(\omega \cdot t, \lambda)$ be the corresponding m-functions. They satisfy the Riccati equation

$$m' + \frac{1}{p}m^2 = q - \lambda y.$$

It is understood that this equation holds for each $t \in \mathbb{R}$.

We change the meaning of z again, and let $z^2 = -\lambda$ be a parameter near $\lambda = \infty$ on the Riemann surface $\mathcal{R}$. We view points $P \in \mathcal{R}$ near ∞ as being parameterized by z. Write $M'_\omega(z)$ for the derivative of the function $t \mapsto M_{\omega\cdot t}(z)$ in $t = 0$: thus $M'_\omega(z) = \frac{\mathrm{d}}{\mathrm{d}t}M_{\omega\cdot t}(z)|_{t=0}$ for each $\omega \in \Omega$. Then

$$M'_\omega(z) + \frac{1}{p}M^2_\omega(z) = q + z^2 y. \tag{4.65}$$

We expand the function $z \mapsto M_\omega(z)$ in a Laurent series near $z = \infty$, obtaining

$$M_\omega(z) = \alpha_1 z + \alpha_0 + \sum_{n=1}^{\infty} \alpha_{-n} z^{-n}.$$

Using the Riccati equation (4.65) one finds

$$\alpha_1^2 = yp, \quad \alpha_0 = -\frac{(py)'}{4y}, \quad \alpha_0' + \frac{\alpha_0^2}{p} + \frac{2\alpha_1\alpha_{-1}}{p} = q. \tag{4.66}$$

In particular, the above derivatives exist; in fact, by using the Cauchy integral formula along a small circle centered at $z = \infty$, one sees that α_{-1} exists and is continuous in $\omega \in \Omega$. It follows that the derivative α_0' exists and is continuous in $\omega \in \Omega$, so the same holds for y, and moreover py has second derivative which is continuous in $\omega \in \Omega$.

Let $\sigma : \mathcal{R} \to \mathcal{R}$ be the hyperelliptic involution $(\lambda, w) \mapsto (\lambda, -w)$ (i.e. the map which interchanges the sheets). It is sometimes convenient to think of M_ω as "the meromorphic extension of $m_+(\omega, \cdot)$ to $\mathcal{R}$". From this point of view, one has $m_-(\omega, \cdot) = M_\omega \circ \sigma(\cdot)$. We then have

$$\begin{aligned} M_\omega(z) = m_+(z) &= \sqrt{py}\, z - \frac{(py)'}{4y} + \sum_{n=1}^{\infty} \alpha_{-n} z^{-n}, \\ M_\omega(z) \circ \sigma(z) = m_-(z) &= -\sqrt{py}\, z - \frac{(py)'}{4y} + \sum_{n=1}^{\infty} (-1)^n \alpha_{-n} z^{-n}. \end{aligned} \tag{4.67}$$

We adopt the convention that $\sqrt{py} < 0$ if g is even, while $\sqrt{py} > 0$ if g is odd. The derivatives in (4.66) and (4.67) are calculated at $t = 0$. Thus, for example, $(py)'$ means $\frac{\mathrm{d}}{\mathrm{d}t}(py)(\omega \cdot t)|_{t=0}$. Let us now write P_i $(1 \leqslant i \leqslant g)$ for the finite poles of M_ω. Note that these poles P_i depend on $\omega \in \Omega$.

We know that $\pi(P_i) \in [\lambda_{2i-1}, \lambda_{2i}]$ for each $i \leqslant i \leqslant g$. Our aim in the next lines is to obtain an explicit formula for M_ω in terms of the poles and of p, q, y.

Let P denote a generic point of the Riemann surface $\mathcal{R}$. Abbreviating $m_\pm(\omega, P)$ to $m_\pm(P)$, we first note that $m_+ - m_- = M_\omega - M_\omega \circ \sigma$ is meromorphic on $\mathcal{R}$ and has zeroes $\{\lambda_0, \dots, \lambda_{2g}\} \subset \mathcal{R}$. It has poles at the inverse images $\pi^{-1}\pi(P_i)$ $(1 \leqslant i \leqslant g)$ and at ∞. Taking account of (4.67), we have

$$(m_+ - m_-)(P) = \frac{2\sqrt{py}\,k(P)}{H(\lambda)}, \tag{4.68}$$

where

$$H(\lambda) = \prod_{i=1}^{g} \bigl[\lambda - \pi(P_i)\bigr],$$

and $k(P)$ is defined by the conditions

$$k(P) = \sqrt{-\bigl(\pi(P) - \lambda_0\bigr)\cdots\bigl(\pi(P) - \lambda_{2g}\bigr)}, \quad k\bigl(0^+\bigr) > 0. \tag{4.69}$$

Next, for each fixed $\omega \in \Omega$, the function $m_+ + m_-$ is meromorphic on the Riemann sphere; i.e., it is a rational function. It has poles at $\pi(P_1), \dots, \pi(P_g)$ and moreover tends to $2\alpha_0$ as $\lambda \to \infty$. This implies that

$$(m_+ + m_-)(P) = \frac{2Q(\lambda)}{H(\lambda)}$$

where $\lambda = \pi(P)$ and $Q(\lambda) = q_g\lambda^g + \cdots + q_1\lambda + q_0$ is a polynomial of degree $\leqslant g$ in λ. It is of degree g whenever $\alpha_0 \neq 0$. Putting together all this information we obtain

$$M_\omega(P) = m_+(\omega, P) = \frac{Q(\lambda) + \sqrt{py}\,k(P)}{H(\lambda)},$$
$$M_\omega \circ \sigma(P) = m_-(\omega, P) = \frac{Q(\lambda) - \sqrt{py}\,k(P)}{H(\lambda)}.$$

Here M_ω is viewed as a meromorphic function of the generic point $P \in \mathcal{R}$. The polynomials Q and H are functions of $\lambda = \pi(P)$, and so can also be viewed as functions on $\mathcal{R}$, for each fixed $\omega \in \Omega$.

Let us now suppose for a moment that none of the poles are ramification points of $\mathcal{R}$. Then $m_-(P_i)$ is finite for each $1 \leqslant i \leqslant g$ and so we must have

$$Q(P_i) = \sqrt{py}\,k(P_i) \quad 1 \leqslant i \leqslant g. \tag{4.70}$$

The above formulas retain validity even if one or more poles P_i are ramification points of $\mathcal{R}$: in fact, if this were not true, then such a point P_i would not be a simple pole for M_ω

(to see this, suppose that $Q(P_i) \neq \sqrt{py}\,k(P_i)$, then compute the derivative of $M_\omega(\cdot)$ with respect to λ at $\lambda = P_i$, and use the local coordinate $z^2 = \lambda - P_i$.)

Equation (4.70) provides g linear relations for the $g+1$ coefficients of Q. To get another relation, note that $\lambda = 0$ is to the left of $\Sigma(L)$. We point out again the fact that we may assume without any loss of generality that $\lambda_0 > 0$. Hence $m_+(\omega, 0) = m_+^0$ and $m_-(\omega, 0) = m_-^0$ have real values. We therefore have

$$q_0 = Q(0) = \frac{(-1)^g [m_+^0 + m_-^0] \prod_{i=1}^g \pi(P_i)}{2}.$$

Now we can determine the coefficients of Q from the following van der Monde system:

$$\begin{pmatrix} 1 & 0 & \dots & 0 \\ 1 & \pi(P_1) & \dots & \pi(P_1)^g \\ \vdots & \vdots & & \vdots \\ 1 & \pi(P_g) & \dots & \pi(P_g)^g \end{pmatrix} \begin{pmatrix} q_0 \\ q_1 \\ \vdots \\ q_g \end{pmatrix} = \begin{pmatrix} Q(0) \\ \sqrt{py}\,k(P_1) \\ \vdots \\ \sqrt{py}\,k(P_g) \end{pmatrix}. \tag{4.71}$$

From now on, we will often abuse the notation, and write P_i instead of $\pi(P_i)$ ($i = 1, \dots, g$), when no confusion arises (i.e., we will omit π). In particular, we can determine the highest-order coefficient $q_g = \alpha_0 = -\frac{(py)'}{4y}$. In fact, letting Δ be the determinant of the matrix on the right-hand side of (4.71), we obtain

$$\begin{aligned} q_g \Delta = {} & \det \begin{pmatrix} P_1 & P_1^2 & \dots & P_1^{g-1} & \sqrt{py}\,k(P_1) \\ \vdots & \vdots & & \vdots & \vdots \\ P_g & P_g^2 & \dots & P_g^{g-1} & \sqrt{py}\,k(P_g) \end{pmatrix} \\ & + (-1)^g q_0 \det \begin{pmatrix} P_1 & P_1^2 & \dots & P_1^{g-1} \\ \vdots & \vdots & & \vdots \\ P_g & P_g^2 & \dots & P_g^{g-1} \end{pmatrix}. \end{aligned}$$

Working out the determinants, we get

$$q_g = \frac{(-1)^g q_0}{\prod_{i=1}^g P_i} + \sum_{i=1}^g \frac{\sqrt{py}\,k(P_i)}{P_i \prod_{r \neq i} (P_i - P_r)}. \tag{4.72}$$

Now we obtain a formula for α_{-1}. The Laurent expansions (4.67) for $m_\pm$ together with (4.68) give

$$2\sqrt{py}\,z + \frac{2\alpha_{-1}}{z} + 2\sum_{k=1}^{\infty} \frac{\alpha_{-2k-1}}{z^{2k+1}} = \frac{2\sqrt{py}\,k(z)}{\prod_{i=1}^g (-z^2 - P_i)}.$$

Multiplying both sides of this relation by $z\prod_{i=1}^{g}(z^2+P_i)$ and comparing the z^{2g}-coefficients , we obtain

$$\alpha_{-1}=\sqrt{py}\left(\frac{1}{2}\sum_{i=0}^{2g}\lambda_i-\sum_{i=1}^{g}P_i\right).$$

Let us now fix $\omega\in\Omega$. Now we will "follow the trajectory $\{\omega\cdot t\}$ through ω". As already remarked, this allows us to think at the functions involved as varying with $t\in\mathbb{R}$. Thus write $m_\pm(t,z)=m_\pm(\omega\cdot t,z)$, $p=p(t), q=q(t), y=y(t), P_i=P_i(t)\ (-\infty<t<\infty)$, $Q=Q(\lambda,t), H=H(\lambda,t)$. Using the formula for q in (4.66) we obtain

$$q(t)=y(t)\left(\sum_{i=0}^{2g}\lambda_i-2\sum_{i=1}^{g}P_i(t)\right)+q_g'(t)+\frac{q_g(t)^2}{p(t)}. \tag{4.73}$$

Here q_g is given by (4.72).

Now, consider

$$m_+'=\left(\frac{\sqrt{p(t)y(t)}\,k(P)+Q(\lambda,t)}{H(\lambda,t)}\right)',\qquad '=\frac{\mathrm{d}}{\mathrm{d}t}.$$

From the Riccati type equation for m_+ we obtain

$$m_+'=\left(\frac{\sqrt{p(t)y(t)}\,k(P)+Q(\lambda,t)}{H(\lambda,t)}\right)'=-\frac{1}{p}m_+^2+q-\lambda y,$$

hence,

$$m_+'=\frac{(\sqrt{py}\,k+Q)'H-H'(\sqrt{py}\,k+Q)}{H^2}=-\frac{1}{p}\frac{(\sqrt{py}\,k+q)^2}{H^2}+q-\lambda y,$$

and multiplying by H^2 we obtain

$$(\sqrt{py}\,k+Q)'H-(\sqrt{py}\,k+Q)H'+\frac{1}{p}(\sqrt{py}\,k+Q)^2=(q-\lambda y)H^2. \tag{4.74}$$

Let us write $k_r=k(P_r)$. If we compute (4.74) at a pole P_r we obtain, since $H(P_r)=H_r=0$ and $\sqrt{py}\,k(P_r)=\sqrt{py}\,k_r=Q(\pi(P_r))$,

$$-(\sqrt{py}\,k_r)H_r'+\frac{1}{p}(2\sqrt{py}\,k_r)^2=0, \tag{4.75}$$

hence we obtain the following important relation

$$\frac{H_r'(t)}{k_r(t)}=\frac{2}{p(t)}\sqrt{p(t)y(t)}. \tag{4.76}$$

What we want to do now is to express the above fraction (4.76) as a product of the poles $P_1(t), \dots, P_g(t)$ of the function $M_{\omega\cdot t}(P)$ To this aim, we compute m_- at $\lambda = 0$, and we have

$$m_-^0(t) = \frac{Q(0,t) - \sqrt{py}\,k(0^+)}{(-1)^g \prod_{i=1}^g P_i(t)},$$

hence

$$\sqrt{py} = \frac{(-1)^{g+1} m_-^0(t) \prod_{i=1}^g P_i(t) + Q(0,t)}{k(0^+)},$$

and (4.76) becomes

$$\frac{H_r'}{k_r} = \frac{2(-1)^{g+1} m_-^0(t) \prod_{i=1}^g P_i(t) + 2Q(0,t)}{p(t)k(0^+)}. \tag{4.77}$$

Hence we have

$$\frac{H_r'(t)}{k_r(t)} = \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)] \prod_{i=1}^g P_i(t)}{p(t)k(0^+)}. \tag{4.78}$$

Finally

$$\frac{H_r'(t)}{P_r(t)k_r(t)} = \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)] \prod_{s\neq r} P_s(t)}{p(t)k(0^+)}. \tag{4.79}$$

We proved the following

THEOREM 4.40. *Suppose that Hypotheses* 4.38 *hold. Then the functions p, q and y satisfy the following relations involving the t-motion of the poles of the meromorphic function $M_\omega(P)$ on $\mathcal{R}$,*

$$\frac{2\sqrt{p(t)y(t)}}{p(t)} = \frac{H_r'(t)}{k_r(t)} = \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)]\prod_{i=1}^g P_i(t)}{p(t)k(0^+)},$$

and

$$q(t) = y(t)\left(\sum_{i=0}^{2g} \lambda_i - 2\sum_{i=1}^{g} P_i(t)\right) + q_g'(t) + \frac{q_g^2(t)}{p(t)},$$

where

$$q_g(t) = -\frac{(p(t)y(t))'}{4y(t)} = \frac{(-1)^g Q(0,t)}{\prod_{i=1}^g P_i(t)} + \sum_{j=1}^{g} \frac{\sqrt{p(t)y(t)}k(P_j(t))}{P_j(t)\prod_{r\neq j}(P_j(t)-P_r(t))}$$
$$= -\frac{p(t)}{2}\frac{\mathrm{d}}{\mathrm{d}t}\left\{\ln\left(\left[m_-^0(t) - m_+^0(t)\right]\prod_{i=1}^{g} P_i(t)\right)\right\}.$$

Now we study the nature of the t-dependence of p, q, y. Clearly this issue is related to that of the pole motion $t \mapsto \{P_1(t), \dots, P_g(t)\}$. We will see that a good deal of information about the pole motion can be obtained by introducing certain "nonstandard" Abel–Jacobi coordinates. In what follows, we will use the language of classical algebraic geometry. We will not pause to give much information concerning general facts of the theory of algebraic curves. We will only give a general outline of the classical theory, and spend a few more lines in the explanation of the main concepts occurring in the theory of the "singular Riemann surfaces". For more details, the reader is referred to such standard texts as [146,112]. For the theory of generalized Jacobian varieties, see [53].

Let $\mathcal{R}$ be the Riemann surface of the algebraic relation

$$w^2 - (\lambda - \lambda_0)\cdots(\lambda - \lambda_{2g}).$$

It was already pointed out that $\mathcal{R}$ is homeomorphic to an analytic g-torus. Let $\{\alpha_i, \beta_i\}$ ($i = 1, \dots, g$) be a homology basis of $\mathcal{R}$. There is one simple standard way to take such a basis: all α_i, β_i ($i = 1, \dots, g$) consist of a simple closed curves satisfying the intersection relations

$$\begin{aligned} &\alpha_i \cap \alpha_j = \beta_i \cap \beta_j = \emptyset, \quad 1 \leqslant i, j \leqslant g, \\ &\alpha_i \cap \beta_j = \begin{cases} \{A_i\} & i = j, \\ \emptyset, & i \neq j \end{cases} \end{aligned} \tag{4.80}$$

where $\{A_i\}$ denotes a point in $\mathcal{R}$ which varies with i, for every $i = 1, \dots, g$. Let $w_1, \dots, w_g$ be a standard basis of normalized differential forms of the first kind on $\mathcal{R}$: to be clearer, $w_1, \dots, w_g$ are holomorphic differentials such that

$$\int_{\alpha_i} w_j = \delta_{ij} \quad \text{and} \quad \int_{\beta_i} w_j = z_{ij},$$

where $z_{ij} \in \mathbb{C}$. The $g \times g$ matrix $Z = (z_{ij})$ is called the *period matrix* of the surface $\mathcal{R}$. This matrix is symmetric and has positive imaginary part [146]. It turns out that the $\mathbb{Z}$-lattice in $\mathbb{C}^g$ spanned by all the vectors of the form

$$\int_c (w_1, \dots, w_g), \quad c = \alpha_1, \dots, \alpha_g, \beta_1, \dots, \beta_g$$

is completely determined once the matrix $P = \binom{I}{Z}$ is given, where I is the $g \times g$ identity matrix. We denote this $\mathbb{Z}$-lattice with Λ^{2g}. Clearly the rank of Λ^{2g} is $2g$. We define the Jacobian variety as

$$J(\mathcal{R}) = \mathbb{C}^g / \Lambda^{2g}.$$

There is another way to describe the Jacobian variety. Any formal sum $\mathcal{D} = \sum_{i=1}^{p} k_i Q_i$, where each $k_i \in \mathbb{Z}$, and Q_i are points in $\mathcal{R}$, is called a *divisor*. The sum of two divisors $\mathcal{D} = \sum_{i=1}^{p} k_i Q_i$ and $\mathcal{D}_1 = \sum_{i=1}^{s} n_i R_i$ is the divisor

$$\mathcal{D} + \mathcal{D}_1 = \sum_{i=1}^{p} k_i Q_i + \sum_{i=1}^{s} n_i R_i.$$

The degree of a divisor $\mathcal{D} = \sum_{i=1}^{p} k_i Q_i$ is the integer $\sum_{i=1}^{p} k_i$. With the usual rules of the summation, the set of all the divisors of the Riemann surface $\mathcal{R}$ is an Abelian additive group. The inverse of a divisor $\mathcal{D} = \sum_{i=1}^{p} k_i Q_i$ is the divisor $-\mathcal{D} = \sum_{i=1}^{p} (-k_i) Q_i$.

Let $f : \mathcal{R} \to \mathbb{C}$ be any meromorphic function. Then f has the same number of zeroes and poles. If $Q_1, \dots, Q_p$ are the zeroes of f and $R_1, \dots, R_p$ are the poles of f (all counted with their multiplicities), then we can associate to f a divisor (f) of degree 0 defined as

$$(f) = \sum_{i=1}^{p} (k_i Q_i - n_i R_i) \quad \left(\sum_{i=1}^{p} (k_i - n_i) = 0 \right)$$

where $k_i, n_i \in \mathbb{Z}^+$ are the multiplicities of the points Q_i, R_i as zeroes or poles of f $(i = i, \dots, p)$. If f and g are two meromorphic functions on $\mathcal{R}$, then $(fg) = (f) + (g)$, $(fg^{-1}) = (f) - (g)$, and $(f) = (g)$ implies $f = cg$, where $c \in \mathbb{C}$ is a constant.

Every divisor of degree g can be thought as an element of $\mathrm{Symm}^g(\mathcal{R})$, the set of unordered g-tuples of points in $\mathcal{R}$. Given any divisor $\mathcal{D}$ of degree g (note that g is the genus of the surface $\mathcal{R}$) we form its class $[\mathcal{D}]$ consisting of all the divisors $\mathcal{D}_1$ of the same degree g such that $\mathcal{D} - \mathcal{D}_1$ is the divisor of a meromorphic function $f : \mathcal{R} \to \mathbb{C}$. Now, let P_* be any fixed point on $\mathcal{R}$ different from the ramification points. It is a classical fact that two divisors $\mathcal{D} = (Q_1, \dots, Q_g)$ and $\mathcal{D}_1 = (R_1, \dots, R_g)$ belong to the same class if and only if

$$\sum_{i=1}^{g} \int_{Q_i}^{R_i} (w_1, \dots, w_g) = Zt,$$

where t is a column vector in $\mathbb{Z}^g$.

To any divisor $\mathcal{D} = (Q_1, \dots, Q_g) \in \mathrm{Symm}^g(\mathcal{R})$ we associate the complex g-vector $(s_1, \dots, s_g) \in \mathbb{C}^g$, given by

$$(s_1, \dots, s_g) = \sum_{i=1}^{g} \int_{P_*}^{Q_i} (w_1, \dots, w_g).$$

We define a map $I : \mathrm{Symm}^g(\mathcal{R}) \to \mathbb{C}^g/\Lambda^{2g}$ as follows

$$I(Q_1, \dots, Q_g) = \sum_{i=1}^{g} \int_{P_*}^{Q_i} (w_1, \dots, w_g) \mod \Lambda^{2g} \in J(\mathcal{R}).$$

This map is called the *Abel map*. It is surjective and, when restricted to an appropriate open dense subset of $\mathrm{Symm}^g(\mathcal{R})$, is bijective. It is clear that $I(Q_1, \dots, Q_g) = I(R_1, \dots, R_g)$ if and only if $(Q_1, \dots, Q_g)$ and $(R_1, \dots, R_g)$ belong to the same class. It is easy to check that $J(\mathcal{R})$ can be identified with the set of the classes $[\mathcal{D}]$ of the divisors $\mathcal{D}$ on $\mathcal{R}$ of degree g. Equivalently, it can be proved that $J(\mathcal{R})$ can be identified as the quotient space of the set of all the divisors on $\mathcal{R}$ of degree 0, modulo the set of the divisors of meromorphic functions on $\mathcal{R}$ (see [146] for more details concerning this last remark).

Now we define the Riemann theta function. Let Z be any g-period matrix (i.e., any symmetric complex $g \times g$ matrix with positive imaginary part). Define $\Theta : \mathbb{C}^g \to \mathbb{C}$ as follows:

$$\Theta(s_1, \dots, s_g) = \Theta(s) = \sum_{t \in \mathbb{Z}^g} \exp\bigl\{\pi \langle t, Zt \rangle + 2\pi \mathrm{i} \langle t, s \rangle\bigr\},$$

where $(s_1, \dots, s_g) \in \mathbb{C}^g$. The function Θ has many important properties; we list some of them:

(i) $\Theta(-s) = \Theta(s)$;
(ii) $\Theta(s + t) = \Theta(s)$, for every integer column $t \in \mathbb{Z}^g$;
(iii) $\Theta(s + Zt) = \exp\{-\pi \langle t, Zt \rangle - 2\pi \mathrm{i} \langle t, s \rangle\}\Theta(s)$, for every column vector $t \in \mathbb{Z}^g$.

It was a Riemann's fundamental idea to compute the zeroes of the function Θ. To this aim, we define the so-called *vector of Riemann constants* $\Delta = (\Delta_1, \dots, \Delta_g) \in \mathbb{C}^g$, where

$$\Delta_k = -\frac{1}{2} z_{kk} + \sum_{j \neq k}^{g} \int_{\alpha_j} \left(\int_{P_*}^{P} w_k \right) w_j \quad (k = 1, \dots, g). \tag{4.81}$$

In order to simplify the notation, if $P \in \mathcal{R}$, we will write

$$w(P) = \int_{P_*}^{P} (w_1, \dots, w_g) \in \mathbb{C}^g.$$

THEOREM 4.41. *Let $s \in \mathbb{C}^g$ be fixed. If the map $F : P \mapsto \Theta(w(P) - s + \Delta)$ does not vanish identically, then it has exactly g zeroes $Q_1, \dots, Q_g \in \mathcal{R}$ such that*

$$s = \sum_{i=1}^{g} \int_{P_*}^{Q_i} (w_1, \dots, w_g) \mod \Lambda^{2g}.$$

Theorem 4.41 provides an answer to the Riemann inversion problem, which consists in associating to each $s \in \mathbb{C}^g$ a divisor $Q_1, \dots, Q_g$ such that $I(Q_1, \dots, Q_g) = s \bmod \Lambda^{2g}$.

In fact, when restricted to $J(\mathcal{R})$, the equation $\Theta(s, Z) = 0$ defines the 1-codimensional analytic subvariety Υ_g of the zero-locus of Θ, called the *Θ-divisor*. It can be shown that Υ_g admits a parametrization

$$\Upsilon_g = \left\{ s \in \mathbb{C}^g \;\middle|\; s = \sum_{j=1}^{g-1} \int_{P_*}^{X_j} (w_1, \dots, w_g) - \Delta \bmod \Lambda^{2g} \right\}, \tag{4.82}$$

where X_j $(j = 1, \dots, g-1)$ are arbitrarily chosen points on $\mathcal{R}$ which are different from the ramification points. If, for some $s \in \mathbb{C}^g$, the map $F : P \mapsto \Theta(w(P) - s + \Delta) \equiv 0$, then $s \in \Upsilon_g$ and there exist points $X_1, \dots, X_{g-1} \in \mathcal{R}$ satisfying (4.82). The g-tuple of points $P_*, X_1, \dots, X_g$ defines a divisor such that $I(P_*, X_1, \dots, X_{g-1}) = s \bmod \Lambda^{2g}$. See [146, Chapter 4, Vol. 2].

Now we go deeper in the examination of the zeroes of Θ. Let $A, B \in \mathcal{R}$, and consider the differential $w_{B,A}$ of the third kind on $\mathcal{R}$, having simple poles at A and B with residues 1 and -1 respectively. Let $s = I(Q_1, \dots, Q_g)$, where $Q_i \in \mathcal{R}$ $(i = 1, \dots, g)$ are different from the ramification points. Applying Theorem 4.41, we see that the zeroes of $F(P) = \Theta(w(P) - s + \Delta)$ are exactly the points Q_i $(i = 1, \dots, g)$. Next, we compute the sum of the residues of the differential $w_{B,A}\, \mathrm{d} \ln F(P)$, to obtain

$$\sum_{i=1}^{g} \int_{P_*}^{Q_i} w_{B,A} = -\frac{\Theta(s + \Delta - w(B))}{\Theta(s + \Delta - w(A))} + c.$$

Another important application of Theorem 4.41 and the parametrization (4.82) is the following fundamental theorem, which provides an answer to the following question: is it possible to express meromorphic functions defined on $\mathcal{R}$ in terms of functions defined on $J(\mathcal{R})$? The answer is positive: first, we use the map $w : P \mapsto \int_{P_*}^{P} (w_1, \dots, w_g)$ which sends the zeroes and the poles of f (which belong to $\mathcal{R}$) into complex g-vectors in $J(\mathcal{R})$, then we use the Riemann Θ-function to express f.

THEOREM 4.42. *Let f be a meromorphic function on $\mathcal{R}$. Let $\mathcal{D} = (f) = P_1 + \dots + P_m - Q_1 - \dots - Q_m$. Let $X_1, \dots, X_{g-1}$ be any $g-1$ points in $\mathcal{R}$ which are different from the ramification points of $\mathcal{R}$ and the points P_i, Q_i $(i = 1, \dots, g)$. Then*

$$f(P) = \delta \prod_{i=1}^{m} \frac{\Theta(w(P) - w(P_i) - \Delta + \sum_{j=1}^{g-1} w(X_j))}{\Theta(w(P) - w(Q_i) - \Delta + \sum_{j=1}^{g-1} w(X_j))},$$

where $\delta \in \mathbb{C}$ depends only on the choice of the points $X_1, \dots, X_g$.

An easy consequence of the above theorem is the following

THEOREM 4.43. *Let f be a meromorphic function defined on $\mathcal{R}$, with*

$$(f) = \sum_{i=1}^{m} (P_i - Q_i)$$

(*it is understood that the points* P_i *and* Q_i $(i = 1, \dots, m)$ *are the zeroes and the poles of* f *respectively*). *Let* $S_1, \dots, S_g$ *be* g *points on* $\mathcal{R}$ (*here some of the points* S_i *may coincide with some of the* P_i*'s or* Q_i*'s*). *Then*

$$\prod_{i=1}^{g} f(S_i) = \gamma \prod_{j=1}^{m} \frac{\Theta(I(S_1, \dots, S_g) - w(P_j) - \Delta)}{\Theta(I(S_1, \dots, S_g) - w(Q_j) - \Delta)},$$

where $\gamma \in \mathbb{C}$ *is a constant which does not depend on the choice of the points* $S_1, \dots, S_g$.

The theory we have just outlined is very useful if one has to face problems where only differentials of the first kind occur, but when we have to consider nonholomorphic differentials as well, things become a little more difficult.

We give a method, essentially due to Fay [53], to solve the Riemann inversion problem when in presence of one nonholomorphic differential. This method uses the concept of singular Riemann surface, which leads to the introduction of the generalized Jacobian variety, the generalized Abel map, and the generalized Riemann Θ-function as well. To begin the discussion, let D be the unit circle. We will denote points on D with z.

Following [53], we build a family $\mathfrak{F}$ of Riemann surfaces over D in the following way: let $A \neq B \in \mathcal{R}$. Let U_A and U_B be disjoint neighborhood of A and B respectively, and $z_A : U_A \to D$, $z_B : U_B \to D$ be local coordinates of A and B. Let

$$\begin{aligned} W = \big\{&(P, z) \mid z \in D,\ P \in \mathcal{R} \setminus (U_A \cup U_B) \text{ or } P \in U_A(U_B) \text{ and} \\ &\big|z_A(P)\big| > |z|\big(|z_B(P)| > |z|\big)\big\}. \end{aligned}$$

Let $\mathcal{S}$ be the surface

$$\mathcal{S}\colon \big\{XY = z \mid (X, Y, z) \in D^3\big\},$$

and define

$$\mathfrak{F} = W \cup \mathcal{S},$$

where the points $(P_A, z) \in (W \cap U_A) \times D$ are identified with $(z_A(P_A), z/z_A(P_A), z) \in \mathcal{S}$ and the points $(P_B, z) \in (W \cap U_B) \times D$ are identified with $(z_B(P_B), z/z_B(P_B), z) \in \mathcal{S}$ $(z \in D)$. We take

$$x = \frac{1}{2}(X + Y) \quad \text{and} \quad y = \frac{1}{2}(X - Y)$$

as coordinates on $\mathcal{S}$. For every fixed $z \in D$, the fiber $\mathcal{R}_z$ over z is a Riemann surface of genus $g + 1$ for which $\mathcal{R}_z \cap \mathcal{S}$ is the surface of $y = \sqrt{x^2 - z}$, having $\pm\sqrt{z}$ as ramification points. The fiber $\mathcal{R}_0$ is a curve of genus $g + 1$ with a double point corresponding to the identification of the points A and B: hence the branches of $\mathcal{R}_0 \cap \mathcal{S}$ are $y = x$ and $y = -x$, with local parameters $x = z_A/2$ and $x = z_B/2$ respectively. Now, choose a canonical basis $\alpha_1(z), \dots, \alpha_g(z), \alpha_{g+1}(z), \beta_1(z), \dots, \beta_g(z), \beta_{g+1}(z)$ for the homology group of

$\mathcal{R}_z$ as follows: $\alpha_1(z), \dots, \alpha_g(z), \beta_1(z), \dots, \beta_g(z)$ are the extensions on $\mathcal{R}_z$ of the canonical basis $\alpha_1, \dots, \alpha_g, \beta_1, \dots, \beta_g$ of the homology group of $\mathcal{R}$ (moreover, we may assume that $\alpha_i, \beta_i \in \mathcal{R} \setminus (U_A \cup U_B)$ $(i = 1, \dots, g)$): then define $\alpha_{g+1}(z) = \partial U_B \times \{z\}$ and, if $|z| < 1/4$, $\beta_{g+1}(z) = l \times \{z\} \cup l_{A,z} \cup l_{B,z} \subset W$, where l is a fixed path from $z_A^{-1}(1/2)$ to $z_B^{-1}(1/2)$ in the (canonically) dissected surface $\mathcal{R}$, $l_{A,z}$ and $l_{B,z}$ are paths from $z_A^{-1}(\sqrt{z})$ to $z_A^{-1}(1/2)$ and from $z_B^{-1}(1/2)$ to $z_B^{-1}(\sqrt{z})$ respectively, which vary continuously with respect to $z \in D$. This choice seems to be a little complicated, but its significance is clear if we note that $\beta_{g+1}(0)$ is simply a path from A to B lying in $\mathcal{R}$.

We have the following

PROPOSITION 4.44. *There are $g + 1$ linearly independent holomorphic 2-forms on $\mathfrak{F}$, having residues $w_1(z), \dots, w_{g+1}(z)$ on $\mathcal{R}_z$, for z in a sufficiently small disc D_ε centered in 0. These residues are a normalized basis of holomorphic differentials on $\mathcal{R}_z$, for $z \neq 0$. For $z = 0$, the differentials $w_1(0), \dots, w_g(0)$ form a normalized basis of holomorphic differentials on $\mathcal{R}$, and $w_{g+1}(0)$ is the normalized differential of the third kind $w_{B,A}$, having simple poles at A and B with residues $\pm 1/2\pi\mathrm{i}$ respectively.*

In particular,

$$w_i(z) = w_i + \zeta_i z\omega + \mathcal{O}(z^2), \quad i = 1, \dots, g,$$

where $\zeta_i \in \mathbb{C}$ is a constant $(i = 1, \dots, g)$, ω is the normalized differential of the second kind on $\mathcal{R}$ having double poles of residue zero at A and B, w_i is the i-th differential of the first kind in $\mathcal{R}$, and $\mathcal{O}(z^2)$ is an expression involving only the holomorphic differentials on $\mathcal{R}$.

Moreover

$$w_{g+1}(z) = w_{B,A} + z\tilde{\omega} + \mathcal{O}(z^2),$$

where $\tilde{\omega}$ is a differential of the second kind on $\mathcal{R}$ having as poles the points A and B, each of order 3.

PROOF. We use without explanations various concepts of algebraic geometry, which are amply discussed by Griffiths and Harris [65]. Let $\mathcal{W}_{\mathfrak{F}}$ and $\mathcal{W}_z$ be the sheafs of holomorphic 2-forms on $\mathfrak{F}$ and on $\mathcal{R}_z$ respectively. Under the residue map $r_z : \mathcal{W}_{\mathfrak{F}} \to \mathcal{W}_z$, the quotient space $\mathcal{W}_{\mathfrak{F}}/\mathcal{R}_z$ is the sheaf consisting, for $z = 0$, of the holomorphic differentials on $\mathcal{R}$, plus the differentials having simple poles at A and B with opposite residues. It turns out that, for every $z \in D$, the cohomology group $H^0(\mathcal{R}_z, \mathcal{W}_{\mathfrak{F}}/\mathcal{R}_z)$ has dimension $g + 1$. Using methods from Fay ([53], Proposition 3.1, page 37), this fact implies that there is a sufficiently small disc D_ε centered at $z = 0$, and differential 2-forms $W_1(z), \dots, W_{g+1}(z)$ on $\mathfrak{F}$, whose first g residues along $z = 0$ give a normalized basis $w_1, \dots, w_g$ of holomorphic differentials on $\mathcal{R}$. For $z = 0$, the $(g + 1)$-th residue gives the differential of the third kind $w_{B,A}$ on $\mathcal{R}$, having simple poles at A and B with residues $\pm 1/2\pi\mathrm{i}$ respectively. By continuity, for $z \in D_\varepsilon$, the residue map computed at the differential forms $W_i(z)$ $(i = 1, \dots, g + 1)$, provides a normalized basis $w_1(z), \dots, w_{g+1}(z)$ of differentials of the first kind on $\mathcal{R}_z$.

Now, let x be the coordinate in a neighborhood $U \subset \mathcal{R}_z \cap \mathcal{S}$ of the double point; then, for every $i = 1, \dots, g+1$, set

$$w_i(z) = \sum_{j=0}^{\infty} a_{i,j}(z) x^j \,\mathrm{d}x + \sum_{n=0}^{\infty} b_{i,n}(z) \frac{x^n}{\sqrt{x^2 - z}} \,\mathrm{d}x,$$

where $a_{i,j}(z)$ and $b_{i,n}(z)$ are holomorphic functions near $z = 0$ for every $j, n \in \mathbb{N}$ and $i = 1, \dots, g+1$. Then, for $i = 1, \dots, g$,

$$w_i = w_i(0) = \sum_{j=0}^{\infty} a_{i,j}(0) x^j \,\mathrm{d}x \pm \sum_{n=0}^{\infty} b_{i,n}(0) x^{n-1} \,\mathrm{d}x,$$

where the sign of the second summand on the right-hand side depends on whether we move in a neighborhood of A or B (where, in fact, the local coordinate is x or $-x$ respectively). If we let $w_i(z) = w_i(x, z) dx$, for every $i = 1, \dots, g+1$, then $b_{i,0}(0) = 0$, $w_i(A, 0) = a_{i,0}(0) + b_{i,1}(0)$, $w_i(B, 0) = a_{i,0}(0) - b_{i,1}(0)$, etc. Moreover

$$\lim_{z \to 0} \frac{w_i(z) - w_i}{z} = \sum_{j \geqslant 0} a'_{i,j}(0) x^j \,\mathrm{d}x \pm \sum_{n \geqslant 0} \left(\frac{1}{2} b_{i,n+1}(0) + x b'_{i,n}(0) \right) x^{n-2} \,\mathrm{d}x$$

is a differential of the second kind on $\mathcal{R}$ whose only double poles are A and B, with opposite principal parts. For $i = g+1$, we have $w_{g+1}(0) = w_{B,A}$, hence $b_{g+1,0}(0) = -1/2\pi \mathrm{i}$, and thus the limit

$$\begin{aligned} \lim_{z \to 0} \frac{w_{g+1}(z) - w_{B,A}}{z} &= \sum_{j \geqslant 0} a'_{g+1,j}(0) x^j \,\mathrm{d}x \\ &\quad \pm \sum_{n \geqslant 0} \left(\frac{b_{g+1,n}(0)}{2x} + x b'_{g+1,n}(0) \right) x^{n-2} \,\mathrm{d}x \end{aligned}$$

is a normalized differential of the second kind on $\mathcal{R}$, having only poles at A and B, each of order 3. The proof follows easily, if we put $\zeta_i = \frac{w_i(A,0) - w_i(B,0)}{4}$. □

The following theorem is fundamental.

THEOREM 4.45. *With the $g+1$-tuple of the normalized basis of holomorphic differentials on $\mathcal{R}_z$ ordered as $(w_{g+1}(z), w_1(z), \dots, w_g(z))$, the period matrix for the Riemann surface $\mathcal{R}_z$ is the $(g+1) \times (g+1)$ matrix*

$$Z_z = \begin{pmatrix} \alpha_i + z\sigma_{gi} & z_{ij} + z\sigma_{ij} \\ \ln z + c_1 + c_2 z & \alpha_j + z\sigma_{jg} \end{pmatrix}_{1 \leqslant i,j \leqslant g} + \mathcal{O}(z^2),$$

where c_1 and c_2 are constants, $\alpha_i = \int_A^B w_i$, σ_{ij} are functions involving the holomorphic differentials on $\mathcal{R}$ together with their derivatives, and $Z = (z_{ij})$ is the $g \times g$ period matrix for $\mathcal{R}$.

PROOF. The proof follows easily from Proposition 4.44, except for the entry $z_{g+1,1}$ of Z_z. However, this follows directly from Proposition 4.44 as well, since $z_{g+1,1} - \ln z$ is a well defined holomorphic function of the variable z in the punctured disc $D_\varepsilon \setminus \{0\}$, and it must be holomorphic in the disc D_ε as well, otherwise $\Im Z_z$ would not be positive definite as $z \to 0$. $\square$

Following Fay again [53], let Λ_z^{2g+2} be the $\mathbb{Z}$-lattice spanned by all vectors of the form

$$\int_c \bigl(w_{g+1}(z), w_1(z), \dots, w_g(z)\bigr) \quad \bigl(c = \alpha_1(z), \dots, \alpha_{g+1}(z), \beta_1(z), \dots, \beta_{g+1}(z)\bigr).$$

From the above theorem, one can easily prove that two vectors $s, s_1 \in \mathbb{C}^{g+1}$ differ by a vector in Λ_z^{2g+2} if and only if, as $z \to 0$, they differ by a vector in the $\mathbb{Z}$-lattice Λ_0^{2g+1} of rank $2g+1$, generated by the rows of the matrix $\left(\begin{smallmatrix} I \\ Z_0 \end{smallmatrix}\right)$, where I is the $(g+1) \times (g+1)$ identity matrix, $Z_0 = \left(\begin{smallmatrix} C & Z \\ 0 & 0 \end{smallmatrix}\right)$, and C is the transpose of the vector $\int_A^B (w_1, \dots, w_g)$. Equivalently, two vectors $s, s_1 \in \mathbb{C}^{g+1}$ satisfy $s - s_1 = \Lambda_z^{2g+2} t$ $(t \in \mathbb{Z}^{2g+2})$, if and only if there exists $t_0 \in \mathbb{Z}^{2g+1}$ such that $s - s_1 = \Lambda_0^{2g+1} t_0 + \mathcal{O}(z)$.

Now, we let $\mathcal{G}$ be the family of the $(g+1)$-dimensional manifolds over the disc D and denote by $\tilde{\pi}$ the canonical map $\tilde{\pi} : \mathcal{G} \to D$. If $z \in D \setminus \{0\}$, the fiber $\tilde{\pi}^{-1}(z)$ is the Jacobian variety $J(\mathcal{R}_z) = \mathbb{C}^{g+1}/\Lambda_z^{2g+2}$ of the Riemann surface $\mathcal{R}_z$, while $\tilde{\pi}^{-1}(0)$ is $J_0(\mathcal{R}) = \mathbb{C}^{g+1}/\Lambda_0^{2g+1}$.

In [72] it is shown that $J_0(\mathcal{R})$ is a manifold, and that the canonical map π is analytic. We want to describe $J_0(\mathcal{R})$.

Let P be the double point of $\mathcal{R}_0$; as already observed, P coincides with the identification of the points $A, B \in \mathcal{R}$. Every divisor $\mathcal{D} = \sum_{Q_i \neq P} n_i Q_i + nP$ on $\mathcal{R}_0$ can be lifted to a divisor $\mathcal{D} = \sum_{Q_i \neq P} n_i Q_i + n(A+B)$ on $\mathcal{R}$ (we abuse slightly the notation). Let $\mathcal{B} - \mathcal{D}$ is the divisor of a meromorphic function f on $\mathcal{R}_0$; if we lift $\mathcal{B} - \mathcal{D}$ on $\mathcal{R}$, then we must have $f(B)/f(A) = 1$, and since f is meromorphic on $\mathcal{R}$ as well, Abel's Theorem gives (see [53])

$$\frac{f(B)}{f(A)} = \exp\left\{\int_{\mathcal{D}}^{\mathcal{B}} v_{B,A} - \sum_{i=1}^{g} \int_A^B k_i w_i\right\} \in \mathbb{C}^*, \tag{4.83}$$

where

$$(k_1, \dots, k_g) = \int_{\mathcal{D}}^{\mathcal{B}} (w_1, \dots, w_g) \in \mathbb{C}^g,$$

and we used the notation $\int_{\mathcal{D}}^{\mathcal{B}} (\cdot) = \sum_{i=1}^{p} \int_{D_i}^{B_i} (\cdot)$. The relation (4.83) holds even if f has a zero or a pole at A: in fact, from the identification of A with B, f must have the same zero or pole at B. Now it is quite natural to associate to a divisor $\mathcal{B}-\mathcal{D}$ of degree 0 on $\mathcal{R}_0$, the equivalence class of the vector

$$\int_{\mathcal{D}}^{\mathcal{B}} (w_{B,A}, w_1, \dots, w_g) \in \mathbb{C}^{g+1} \quad \operatorname{mod} \Lambda_0^{2g+1},$$

and $J_0(\mathcal{R})$ is the group of the equivalence classes of the divisors of degree 0 on $\mathcal{R}_0$, with two divisors $\mathcal{D}$ and $\mathcal{D}'$ identified if $\mathcal{D}-\mathcal{D}'$ is the divisor of a meromorphic function on $\mathcal{R}_0$, i.e. a function satisfying $f(B)/f(A)=1$.

The exact sequence of groups

$$0 \longrightarrow \mathbb{C}^* \xrightarrow{\Phi} J_0(\mathcal{R}) \xrightarrow{\Psi} J(\mathcal{R}) \longrightarrow 0$$

where, for every $r \in \mathbb{C}^*$, $\Phi(r)$ is the class of the divisor of any meromorphic function on $\mathcal{R}$ with $f(B)/f(A)=r$, and Ψ is the projection $J_0(\mathcal{R}) \to J(\mathcal{R})$, gives the fundamental identification

$$J_0(\mathcal{R}) \cong \mathbb{C}^* \times J(\mathcal{R}).$$

We call $J_0(\mathcal{R})$ the *generalized Jacobian variety of* $\mathcal{R}$. If $\tilde{s} = (z_0, z_1, \dots, z_g) \in \mathbb{C}^{g+1}$ is a point in the universal cover of $J_0(\mathcal{R})$, then $\Phi(r)$ is the class of $(\ln r, 0, \dots, 0)$ (mod Λ_0^{2g+1}), and $\Psi(\tilde{s})$ is the class of $(z_1, \dots, z_g) \in \mathbb{C}^g$ in $J(\mathcal{R})$.

The generalized Jacobian $J_0(\mathcal{R})$ is the natural setting for the solution of the Riemann inversion problem when in the presence of a differential of the third kind, as stated in the following

THEOREM 4.46. *Let A and B be two distinct points on $\mathcal{R}$, and let $\mathcal{D}$ be a divisor of degree $g+1$ not containing A and B. Then for every $r \in \mathbb{C}^*$ and $z \in \mathbb{C}^g$, there is a unique divisor $\mathcal{B}$ of degree $g+1$ (not containing A and B) such that*

$$\int_{\mathcal{D}}^{\mathcal{B}} (w_{B,A}, w_1, \dots, w_g) = (\ln r, z_1, \dots, z_g) \in \mathbb{C}^{g+1}/\Lambda_0^{2g+1}. \tag{4.84}$$

Let P_* be a fixed point on $\mathcal{R}_0$ different from the ramification points and the double point of $\mathcal{R}_0$. The map $I_0 : \mathrm{Symm}^{g+1}(\mathcal{R}_0) \to J_0(\mathcal{R})$ defined by

$$I_0(P_0, \dots, P_g) = \sum_{i=0}^{g} \int_{P_*}^{P_i} (w_{B,A}, w_1, \dots, w_g) \quad \operatorname{mod} \Lambda_0^{2g+1}$$

is the generalized Abel map with base point P_*.

We now want to describe a method which uses Θ-functions to express meromorphic functions on the generalized Jacobian. The standard theory must be suitably adapted for our purpose.

Let $\tilde{s} = (z, s) \in \mathbb{C} \times \mathbb{C}^g$. The generalized Θ-function is defined as the map

$$\Theta_0 : \mathbb{C}^{g+1} \to \mathbb{C} : \tilde{s} \mapsto \mathrm{e}^{z/2}\Theta\left(s + \frac{1}{2}q\right) + \mathrm{e}^{-z/2}\Theta\left(s - \frac{1}{2}q\right), \tag{4.85}$$

where Θ is the Riemann Θ-function on $J(\mathcal{R})$, and

$$q = \int_A^B (w_1, \dots, w_g).$$

It is worth noting that Θ_0 has the property that if we shift the vector $\tilde{s}$ by a period vector in the lattice Λ_0^{2g+1} (i.e. by a vector $Z_0 t$, where t is a $\mathbb{Z}^{g+1}$-column), then Θ_0 is multiplied by a simple exponential.

Now, take a point $P \in \mathcal{R}$ different from the ramification points and the points A, B, then consider the function

$$F(P) = \Theta_0\bigl(\tilde{w}(P) - v\bigr),$$

where $v \in \mathbb{C}^{g+1}$,

$$\tilde{w}(P) = \int_{P_*}^P (w_{B,A}, w_1, \dots, w_g),$$

and P_* is any fixed base point. The following holds:

PROPOSITION 4.47. *If the function $F(P)$ does not vanish identically on $\mathcal{R}_0$, then it has exactly $g+1$ zeros* (*possibly with multiplicities*).

PROOF. As in the case of the classical Θ-function, we canonically dissect $\mathcal{R}_0$, and compute

$$\begin{aligned}&\frac{1}{2\pi\mathrm{i}}\int_{\partial\mathcal{R}_0} \mathrm{d}\ln F(P)\\ &\quad= \frac{1}{2\pi\mathrm{i}}\int_{\partial\mathcal{R}} \mathrm{d}\ln F(P) + \operatorname{Res}\mathrm{d}\ln F(B) + \operatorname{Res}\mathrm{d}\ln F(A).\end{aligned} \tag{4.86}$$

The first integral on the right side of (4.86) is exactly g, while, as a simple computation shows,

$$\operatorname{Res}\mathrm{d}\ln F(B) = \operatorname{Res}\mathrm{d}\ln F(A) = \frac{1}{2},$$

and the proof follows easily. □

The above proposition suggests what has to be done: we have to introduce a generalized Riemann vector $\Delta_0 \in \mathbb{C}^{g+1}$, and prove results analogous to those of the classical theory.

We define Δ_0 in the following way:

$$\Delta_0 = (\Delta_*, \Delta_1) = \left(\sum_{i=1}^{g} \int_{\alpha_i} \left(\int_{P_*}^{P} w_i \right) w_{B,A}, \Delta - \frac{w(B) + w(A)}{2} \right) \in \mathbb{C} \times \mathbb{C}^g,$$

where $\Delta \in \mathbb{C}^g$ is the Riemann vector in $J(\mathcal{R})$, whose coordinates are defined in (4.81). Note that Δ_0 depends only on the choice of the base point P_* and the canonical dissection of $\mathcal{R}_0$.

The natural extension of Theorem 4.41 to the setting of singular Riemann surfaces is the following (for a proof, see [53]):

THEOREM 4.48. *For every fixed* $\tilde{s} \in \mathbb{C}^{g+1}$, *if the function* $\Theta_0(\tilde{w}(P) - \tilde{s} + \Delta_0)$ *does not vanish identically, then it has exactly* $g + 1$ *zeros* $P_0, \dots, P_g$ *such that*

$$\tilde{s} = I_0(P_0, \dots, P_g).$$

The analytic noncompact subvariety Υ_0 of $J_0(\mathcal{R})$ defined by the equation $\Theta_0(\tilde{s}) = 0$ is the Θ-divisor of the generalized Jacobian variety. In analogy to the case of the Riemann surface $\mathcal{R}$, Υ_0 admits a parametrization which is very similar to that of Eq. (4.82), i.e.,

$$\Upsilon_0\colon \left\{ \tilde{s} = \sum_{j=1}^{g} \tilde{w}(X_j) - \Delta_0 \bmod \Lambda_0^{2g+1} \right\},$$

where X_j $(j = 1, \dots, g)$ are arbitrarily chosen points on $\mathcal{R}$ different from the ramification points and A, B. It is clear that the Θ-divisor is the set of the solutions of the equation

$$e^{z/2}\Theta\left(s + \frac{1}{2}q\right) - e^{-z/2}\Theta\left(s - \frac{1}{2}q\right) = 0. \tag{4.87}$$

It is possible to retrieve the following parametric form for points on the Θ-divisor:

$$\begin{cases} s = I(P_1, \dots, P_g) - \Delta_1, \\ z = -\ln \dfrac{\Theta(s - \Delta - w(A))}{\Theta(s - \Delta - w(B))} + c = -\ln \dfrac{\Theta(s + (w(B) - w(A))/2)}{\Theta(s + (w(A) - w(B))/2)} + c. \end{cases} \tag{4.88}$$

It is clear that (4.88) follows from (4.87), up to an additive constant. We can formulate a generalized version of Theorem 4.43, as follows.

THEOREM 4.49. *Let* f *be a meromorphic function on* $\mathcal{R}_0$ *such that* $(f) = \mathcal{D} - \mathcal{B}$, *where* $\mathcal{D} = Q_1 + \cdots + Q_m$ *and* $\mathcal{B} = R_1 + \cdots + R_m$ *are two divisors of the same degree* m. *If*

$X_1 + \cdots + X_g$ is a divisor of degree g such that every X_j is different from the points Q_i and R_i and the ramification points of $\mathcal{R}_0$, then

$$f(P) = \delta \prod_{i=1}^{m} \frac{\Theta_0(\tilde{w}(P) - \tilde{w}(Q_i) - \Delta_0 + \sum_{j=1}^{g} \tilde{w}(X_j))}{\Theta_0(\tilde{w}(P) - \tilde{w}(R_i) - \Delta_0 + \sum_{j=1}^{g} \tilde{w}(X_j))},$$

where δ is a constant which depends on the choice of the points $X_1, \dots, X_g \in \mathcal{R}$.

Now, using methods from [146] together with Theorems 4.48 and 4.49, we can prove a generalization of Theorem 4.43, i.e.

THEOREM 4.50. *Let $P_0, \dots, P_g$ be any $(g+1)$-tuple of points of $\mathcal{R}_0$ different from the ramification points and A, B. Let f be a meromorphic function on $\mathcal{R}_0$, and let $(f) = \mathcal{D} - \mathcal{B} = Q_1 + \cdots + Q_m - R_1 - \cdots - R_m$ be the divisor of f. Then*

$$f(P_0) f(P_1) \cdots f(P_g) = \gamma \prod_{i=1}^{m} \frac{\Theta_0(I_0(P_0, \dots, P_g) - \tilde{w}(Q_i) - \Delta_0)}{\Theta_0(I_0(P_0, \dots, P_g) - \tilde{w}(R_i) - \Delta_0)}, \tag{4.89}$$

where γ does not depend on the choice of the points $P_0, \dots, P_g \in \mathcal{R}$.

We have given a general outline of basic facts concerning singular hyperelliptic Riemann surfaces. Although we have considered only surfaces with only one singular point, it is worth noting that all the above reasoning extend to the case of surfaces having more than one singular point as well. Obviously, the definitions must be suitably adapted; but see [53] for a good discussion of this topic.

Now we apply the above results to our particular case. We review developments in [96]. Let us introduce the following differential forms on the Riemann surface $\mathcal{R}$:

$$v_{r-1} = \frac{\lambda^{r-2} \mathrm{d}\lambda}{k(P)}, \quad \lambda = \pi(P),\ 1 \leqslant r \leqslant g+1.$$

Note that $v_1, \dots, v_g$ are holomorphic differentials, while $v_0 = \frac{\mathrm{d}\lambda}{\lambda k(P)}$ is not holomorphic, but is a differential of the third kind with simple poles at 0^+ and 0^- with residues

$$\frac{1}{k(0^{\pm})} = \frac{\pm 1}{\sqrt{\prod_{i=0}^{2g} \lambda_i}}$$

respectively.

Let $\omega \in \Omega$, and let $P_1(t), \dots, P_g(t)$ be the finite poles of $M_{\omega \cdot t}$. Abusing notation slightly, write

$$v_{r-1}(t) = \sum_{i=1}^{g} \int_{P_*}^{P_i(t)} v_{r-1}, \quad 1 \leqslant r \leqslant g+1. \tag{4.90}$$

Here P_* is a fixed point of $\mathcal{R}$ different from 0^+ and 0^-.

Differentiating, and simplifying the notation, we obtain

$$v'_{r-1}(t) = \sum_{j=1}^{g} \frac{P_j^{r-2} P'_j}{k(P_j)} = \sum_{j=1}^{g} \frac{P_j^{r-1} P'_j}{P_j k(P_j)}.$$

We have

$$H'(P_r) = \left(\prod_{j=1}^{g} (\lambda - P_j) \right)' \Bigg|_{\lambda = P_r} = -P'_r \prod_{s \neq r} (P_r - P_s). \tag{4.91}$$

Note that

$$\prod_{s \neq r} (P_r - P_s) = \sum_{j=0}^{g-1} \theta^{(r)}_{g-j-1} P_r^j \tag{4.92}$$

where $\theta^{(r)}_{g-j-1}$ is $(-1)^{g-j-1}$ times the $(g-j-1)$-th elementary symmetric function in $(P_1, \ldots, \hat{P}_r, \ldots, P_g)$.

If we let

$$A = \begin{pmatrix} 1 & \theta_1^{(1)} & \cdots & \theta_{g-1}^{(1)} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & \theta_1^{(g)} & \cdots & \theta_{g-1}^{(g)} \end{pmatrix},$$

then we can rewrite (4.92) as follows

$$A \begin{pmatrix} \frac{P_1^{g-1} P'_1}{k(P_1) P_1} & \cdots & \frac{P_g^{g-1} P'_g}{k(P_g) P_g} \\ \vdots & \ddots & \vdots \\ \frac{P'_1}{k(P_1) P_1} & \cdots & \frac{P'_g}{k(P_g) P_g} \end{pmatrix} = \mathrm{diag} \left(\frac{(-1)^g [m_-^0 - m_+^0] \prod_{r \neq s} P_s}{p(t) k(0^+)} \right)_{r=1 \ldots g}.$$

Multiplying both sides on the right by $\begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix}$ we obtain

$$A \begin{pmatrix} v'_{g-1} \\ \vdots \\ v'_0 \end{pmatrix} = \begin{pmatrix} \frac{-[m_-^0(t) - m_+^0(t)] \theta_{g-1}^{(1)}}{p(t) k(0^+)} \\ \vdots \\ \frac{-[m_-^0(t) - m_+^0(t)] \theta_{g-1}^{(g)}}{p(t) k(0^+)} \end{pmatrix}.$$

Multiplying by A^{-1} we have

$$\begin{pmatrix} v'_{g-1} \\ \vdots \\ v'_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ -\frac{[m_-^0(t)-m_+^0(t)]}{p(t)k(0^+)} \end{pmatrix},$$

hence

$$v'_0(t) = -\frac{[m_-^0(t) - m_+^0(t)]}{p(t)k(0^+)}. \tag{4.93}$$

This implies that

$$\begin{aligned} v_{r-1}(t) &= \sum_{j=1}^{g} \int_{P_*}^{P_j(t)} v_{r-1} \\ &= \begin{cases} c_{r-1}, & r = 2, \dots, g, \\ c_0 - \displaystyle\int_0^x \frac{[m_-^0(s) - m_+^0(s)]}{p(s)k(0^+)}\,\mathrm{d}s, & r = 1. \end{cases} \end{aligned} \tag{4.94}$$

From (4.91) and (4.78), we get the following important formula describing the pole motion

$$P'_r(t) = \frac{(-1)^g k(P_r(t))[m_-^0(t) - m_+^0(t)]\prod_{i=1}^g P_i(t)}{p(t)k(0^+)\prod_{s\neq r}(P_r(t) - P_s(t))}, \quad 1 \leqslant r \leqslant q. \tag{4.95}$$

Note that (4.95) states that a pole $P_j(t)$ $(1 \leqslant j \leqslant g)$ has 0 derivative if and only if it attains one of the values $\lambda_{2j-1}, \lambda_{2j}$ in the resolvent interval containing it: when it reaches such a value, then it jumps from one sheet to the other in the Riemann surface $\mathcal{R}$, and begins moving in the opposite direction in the interval.

We see that the quantities $v_0(t), \dots, v_{g-1}(t)$ are known once $p(t) = p(\omega \cdot t)$, $m_+^0(t)$, and $m_-^0(t)$ are given, while $v_g(t)$ is as yet undetermined. At this point we propose to study the pole motion by introducing an appropriate Abel map which sends the pole divisor $\{P_1(t), \dots, P_g(t)\}$ into a generalized Jacobian variety. It will turn out that the lack of an explicit formula for $v_g(t)$ is related to the fact the Abel map sends the pole divisor into Υ_0. Thus, roughly speaking, $v_g(t)$ is determined implicitly by $v_0(t), \dots, v_{g-1}(t)$.

Let $\alpha_1, \dots, \alpha_g, \beta_1, \dots, \beta_g$ be a homology basis on $\mathcal{R}$, satisfying the intersection relations (4.80). Since v_0 is a differential of the third kind on $\mathcal{R}$, the natural setting for studying the pole motion is the surface $\mathcal{R}_0$ obtained, as before, by building the family $\{\mathcal{R}_z, z \in D \setminus \{0\}\}$ of Riemann surfaces, each with double points $0^+, 0^- \in \mathcal{R}$, and then letting $z \to 0$. The surface $\mathcal{R}_0$ has a double point corresponding to the identification of the points $0^\pm \in \mathcal{R}$.

Now, the differentials $v_0, v_1, \dots, v_g$ are not normalized. In order to use instruments from the theory described above, we introduce the normalizing invertible $(g+1)\times(g+1)$ complex matrix

$$C_0 = \begin{pmatrix} c_{00} & c_{01} & \dots & c_{0g} \\ 0 & & & \\ \vdots & & C & \\ 0 & & & \end{pmatrix},$$

such that

$$\begin{pmatrix} v_0 \\ v_1 \\ \vdots \\ v_g \end{pmatrix} = C_0 \begin{pmatrix} w_0 \\ w_1 \\ \vdots \\ w_g \end{pmatrix}.$$

Here the differentials $w_0, w_1, \dots, w_g$ are the normalized differentials considered before, hence $w_1, \dots, w_g$ are a basis of holomorphic differentials on $\mathcal{R}$; also, w_0 is a differential of the third kind on $\mathcal{R}$, having poles at $0^{\pm}$ with residue $\pm 1/2\pi\mathrm{i}$ respectively, and such that $\int_{\alpha_i} w_0 = 0$, for every $i = 1, \dots, g$.

We are interested in the restriction of the map I_0 (which by abuse of terminology we again call I_0) to the set $\mathrm{Symm}^g(\mathcal{R}_0)$ of unordered g-tuples $\{P_1, \dots, P_g\}$ of points in $\mathcal{R} \setminus \{0^+, 0^-\}$, where $\mathrm{Symm}^g(\mathcal{R}_0)$ is viewed as a subset of $\mathrm{Symm}^{g+1}(\mathcal{R}_0)$ by setting $P_0 = P_*$. In particular, we wish to describe the image $I_0(\mathrm{Symm}^g(\mathcal{R}_0)) \subset J_0(\mathcal{R})$.

Let Θ_0 be the generalized Riemann Θ-function. It is a simple observation that, if $\Theta_0(\tilde{s}) = 0$, then $\Theta_0(\tilde{s} + C_0^{-1}\lambda) = 0$ for all $\lambda \in \Lambda_0$. Define

$$\Upsilon = \left\{ \sum_{i=1}^{g} \int_{P_*}^{P_i} (v_0, v_1, \dots, v_g) \mid P_1, \dots, P_g \in \mathcal{R} \setminus \left\{0^+, 0^-\right\} \right\} \subset \mathbb{C}^{g+1}.$$

Then $\varsigma \in \Upsilon$ if and only if $\Theta_0(C_0^{-1}\varsigma - \Delta_0) = 0$. It follows easily that

$$\Upsilon_0 = \left\{ (\varsigma - C_0\Delta_0) \bmod \Lambda_0 \mid \varsigma \in \Upsilon \right\}.$$

Thus the pole motion $\{P_1(t), \dots, P_g(t)\} \mapsto I_0(P_1(t), \dots, P_g(t)\}$ takes place in the affine translate Υ of Υ_0, and also in Υ_0 itself via the relation $\{P_1(t), \dots, P_g(t)\} \mapsto C_0^{-1}[I_0(P_1(t), \dots, P_g(t))] - \Delta_0$.

Now recall the expression for $2\sqrt{py}$ as in (4.78), i.e.,

$$2\sqrt{p(t)y(t)} = \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)] \prod_{i=1}^{g} P_i(t)}{k(0^+)}.$$

If we put

$$\delta(t) = \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)]}{2k(0^+)},$$

then

$$\sqrt{p(t)y(t)} = \delta(t)\prod_{i=1}^{g} P_i(t). \tag{4.96}$$

Next, consider the function $P \mapsto \pi(P)$; it is a meromorphic function having a double pole at ∞ and zeros at 0^+ and 0^-. Let $P_0 = P_*$. It follows that (4.96) is the restriction of a well defined meromorphic function defined on $J_0(\mathcal{R})$, to Υ_0. Note that in general this restriction is not any more a meromorphic function on Υ_0. These observations, together with Theorem 4.50, provide the proof of the following important

THEOREM 4.51. *$\sqrt{p(t)y(t)}$ coincides with the restriction of a meromorphic function, defined on $J_0(\mathcal{R})$, to Υ_0.*

In particular

$$\begin{aligned}\sqrt{p(t)y(t)} &= \frac{(-1)^{g+1}[m_-^0(t) - m_+^0(t)]\prod_{i=1}^{g}\pi(P_i(t))}{2k(0^+)}\\ &= \delta(t)\gamma\frac{\Theta_0(C_0^{-1}[I_0(P_1(t),\dots,P_g(t))] - \int_{P_*}^{0^+}(w_0,w_1,\dots,w_g) - \Delta_0)}{\Theta_0^2(C_0^{-1}[I_0(P_1(t),\dots,P_g(t))] - \int_{P_*}^{\infty}(w_0,w_1,\dots,w_g) - \Delta_0)}\\ &\quad\times\frac{\Theta_0(C_0^{-1}[I_0(P_1(t),\dots,P_g(t))] + \int_{P_*}^{0^+}(w_0,w_1,\dots,w_g) - \Delta_0)}{\Theta_0^2(C_0^{-1}[I_0(P_1(t),\dots,P_g(t))] - \int_{P_*}^{\infty}(w_0,w_1,\dots,w_g) - \Delta_0)}.\end{aligned} \tag{4.97}$$

Here γ does not depend on the choice of $P_j(t)$ $(1 \leqslant j \leqslant g)$.

The following implicit relation holds between the components of $(w_0(t),\dots,w_g(t)) = C_0^{-1}[I_0(P_1(t),\dots,P_g(t))] = \sum_{i=1}^{g}\int_{P_*}^{P_i(t)}(w_0,\dots,w_g)$:

$$\Theta_0\left(\sum_{i=1}^{g}\int_{P_*}^{P_i(t)}(w_0,\dots,w_g) - \Delta_0\right) = 0.$$

Another way of retrieving formula (4.97) is presented in [156], Section 8. In that paper, formulas for the expression on $J_0(\mathcal{R})$ of all the elementary symmetric functions of g points on $\mathcal{R}$ are obtained, depending on the logarithmic derivative of a well-known Θ-quotient.

We now discuss another approach to the study of the pole motion which is based on the Baker–Akhiezer function $\varphi(t,P)$ of Eqs. (SL_ω). Fix $\omega \in \Omega$. For each $\lambda \in \mathbb{C}$ which is not a pole of $m_+(0,\lambda)$, let $\varphi_+(t,\lambda)$ be the solution of (4.24_ω) which satisfies $\varphi_+(0,\lambda) = 1, \varphi'(0,\lambda) = \frac{m_+(0,\lambda)}{p(0)}$. Similarly, define $\varphi_-(t,\lambda)$ for each $\lambda \in \mathbb{C}$ which is not a pole of $m_-(0,\lambda)$. It turns out that, for each $t \in \mathbb{R}$, these two functions glue together to form a single meromorphic function $\varphi(t,z)$ on the punctured Riemann surface $\mathcal{R} \setminus \{\infty\}$. This function has an essential singularity at $\infty \in \mathcal{R}$. If $z = \frac{1}{\sqrt{-\lambda}}$ is a local parameter at ∞, then by (4.67):

$$\varphi(t, z) = \exp\left(\frac{-1}{z} \int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s\right) f(t, z)$$

where $f(t, \cdot)$ is holomorphic on some disc in the z-plane centered at $z = 0$.

Unfortunately, one cannot apply the Abel Theorem to $\varphi(t, \cdot)$, because it is not meromorphic at ∞. However, following [35], we analyze the differential form $w = d \ln \varphi$. We note the following interesting features of w:

(a) w has a simple pole at $P_i(0)$ with residue -1 $(1 \leqslant i \leqslant g)$.

(b) w has a simple pole at $P_i(t)$ with residue 1 $(1 \leqslant i \leqslant g)$.

(c) w has a pole of order 2 at ∞, and

$$w = \left(\int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s\right) \frac{\mathrm{d}z}{z^2} + \cdots$$

near $z = 0$.

(d) φ is single-valued on $\mathcal{R} \setminus \{\infty\}$, and hence $\int_{\alpha_j} w = 2\pi \mathrm{i} m_j$ and $\int_{\beta_j} w = 2\pi \mathrm{i} n_j$ where $m_j, n_j \in \mathbb{Z}$ $(1 \leqslant j \leqslant g)$.

Following the developments in [35], we let η be the differential of the second kind on $\mathcal{R}$ which has a pole of order 2 at ∞ and which is normalized so that $\int_{\alpha_j} \eta = 0$ $(1 \leqslant j \leqslant g)$. As usual, let $w_1, \ldots, w_g$ be the normalized basis of holomorphic differentials on $\mathcal{R}$. Let $w_{P_i(0), P_i(t)}$ be the differential of the third kind on $\mathcal{R}$ having simple poles at $P_i(0)$ and $P_i(t)$ with residues -1 and $+1$ respectively $(1 \leqslant i \leqslant g)$, and normalized in such a way that

$$\int_{\alpha_j} w_{P_i(0), P_i(t)} = 0 \quad (1 \leqslant i, j \leqslant g).$$

This normalization and Riemann's bilinear relation [112] ensure that

$$\int_{\beta_j} w_{P_i(0), P_i(t)} = \int_{P_i(0)}^{P_i(t)} w_j \mod \Lambda^{2g} \quad (1 \leqslant i, j \leqslant g).$$

It is clear now that

$$w = \int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s \eta + \sum_{i=1}^{g} w_{P_i(0), P_i(t)} + \sum_{j=1}^{g} \gamma_j w_j,$$

where $\gamma_1, \dots, \gamma_g$ are complex constants. Since $\int_{\alpha_j} w = 2\pi \mathrm{i} m_j$, we see that $\gamma_j = 2\pi \mathrm{i} m_j$ $(1 \leqslant j \leqslant g)$. Since $\int_{\beta_k} w = 2\pi \mathrm{i} n_k$, we see that

$$2\pi \mathrm{i} n_k = -\int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s U_k + \sum_{i=1}^{g} \int_{P_i(0)}^{P_i(t)} w_k + \sum_{i=1}^{g} 2\pi \mathrm{i} m_j z_{jk},$$

where $U_k = -\int_{\beta_k} \eta$ $(1 \leqslant k \leqslant g)$. We thus find

$$\sum_{i=1}^{g} \int_{P_i(0)}^{P_i(t)} w_k = 2\pi \mathrm{i}\left(n_k - \sum_{j=1}^{g} m_j z_{jk}\right) + \left(\int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s\right) U_k \quad (1 \leqslant k \leqslant g).$$

Let us consider the standard Abel map $I : \mathrm{Symm}^g(\mathcal{R}) \to J(\mathcal{R})$. We see that the pole motion $t \to \{P_1(t), \dots, P_g(t)\}$ is mapped into $J(\mathcal{R})$, and assumes a very suggestive form, i.e.,

$$I\big(P_1(t), \dots, P_g(t)\big) = c + \left(\int_0^t \sqrt{\frac{y(s)}{p(s)}}\, \mathrm{d}s\right) U \mod \Lambda^{2g} \tag{4.98}$$

where c is a constant vector and $U = (U_1, \dots, U_g)$.

This approach, however, does not provide a solution of our difficulty concerning the implicit nature of the pole motion. In fact, from (4.79) and Theorem 4.40, we see that the function $\sqrt{\frac{y(t)}{p(t)}}$ depends on the product $\prod_{i=1}^{g} P_i(t)$. Thus (4.98) gives the pole motion implicitly. At this point one can use the change of variable

$$\frac{\mathrm{d}\tilde{t}}{\mathrm{d}t} = \prod_{i=1}^{g} P_i(t),$$

as in [2]. With respect to this new variable, the motion $\tilde{t} \to \{P_1(\tilde{t}), \dots, P_g(\tilde{t})\}$ defines a motion along a straight line in $J(\mathcal{R})$ whose velocity is given by

$$\frac{(-1)^{g+1}[m_-^0(\tilde{t}) - m_+^0(\tilde{t})]}{2p(\tilde{t})k(0^+)}.$$

Again, the implicit relation seen earlier between v_g and $(v_0, \dots, v_{g-1})$ is reflected here in the relation between t and $\tilde{t}$.

Theorem 4.40 ensures that, if Hypotheses 4.38 hold, then there exist relations of algebro-geometric type for the coefficients $p(t), q(t), y(t)$ and for the Weyl m-functions $m_\pm$ satisfying the Riccati equation (4.25). Going backwards, we seek to determine if a fixed algebro-geometric configuration determines the coefficients of a Sturm–Liouville operator.

To this end, we fix the Riemann surface $\mathcal{R}$ of genus g of the algebraic relation

$$w^2 = -(\lambda - \lambda_0)(\lambda - \lambda_1)\cdots(\lambda - \lambda_{2g})$$

where $\lambda_i \in \mathbb{R}^+$ $(0 \leqslant i \leqslant 2g)$ and are all distinct. Let $\tilde{P}_1, \ldots, \tilde{P}_g$ be points on $\mathcal{R}$ such that $\lambda_{2i-1} \leqslant \tilde{P}_i \leqslant \lambda_{2i}$ $(1 \leqslant i \leqslant g)$. Define

$$H_0(\lambda) = \prod_{i=1}^{g} \bigl(\lambda - \pi(\tilde{P}_i)\bigr).$$

Let $\tilde{\Omega}$ be a compact metric space, let $\{\tilde{\tau}_t \mid t \in \mathbb{R}\}$ be a continuous one-parameter group of homeomorphisms of $\tilde{\Omega}$, and let $\tilde{\nu}$ be a $\{\tilde{\tau}_t\}$-ergodic measure on $\tilde{\Omega}$ such that $\tilde{\Omega}$ is the topological support of $\tilde{\nu}$. Let $p : \tilde{\Omega} \to \mathbb{R}$ and $\mathcal{M}_1 : \tilde{\Omega} \to \mathbb{R}$ be positive bounded continuous functions. Suppose further that the function $\tilde{\omega} \mapsto \frac{\mathrm{d}}{\mathrm{d}t}\mathcal{M}_1(\tilde{\tau}(\tilde{\omega}))|_{t=0} : \tilde{\Omega} \to \mathbb{R}$ is defined and continuous. Fix $\tilde{\omega} \in \tilde{\Omega}$, and write $p(t) = p(\tilde{\tau}_t(\tilde{\omega}))$, $\mathcal{M}_1(t) = \mathcal{M}_1(\tilde{\tau}_t(\tilde{\omega}))$.

Let $(P_1(t), \ldots, P_g(t))$ be the solution of the following system of first-order differential equations

$$\frac{-P_r'(t)\prod_{s\neq r}(P_r(t) - P_s(t))}{k(P_r(t))} = \frac{(-1)^{g+1}\mathcal{M}_1(t)\prod_{i=1}^{g} P_i(t)}{p(t)k(0^+)} \qquad (1 \leqslant r \leqslant g) \tag{4.99}$$

with initial condition $P_r(0) = \tilde{P}_r$ for every $r = 1, \ldots, g$ (i.e. the analogue of (4.95)), and $k(P)$ is the meromorphic function on $\mathcal{R}$ defined in (4.69). Note that (4.99) implies that the motion of the points P_r $(1 \leqslant r \leqslant g)$ has the following properties:

(1) $P_r'(t)$ attains the value 0 only at the points t such that $P_r(t)$ is a ramification point;

(2) when $P_r(t)$ reaches a ramification point, say at $t = \tilde{t}$, then $P_r(t)$ jumps from a sheet to the other in the Riemann surface $\mathcal{R}$, and begins to move towards the opposite ramification point in the resolvent interval containing it (this can be seen by introducing a parameter $z = \sqrt{\lambda - P_r(\tilde{t})}$ in a neighborhood of the ramification point $P_r(\tilde{t})$ of $\mathcal{R}$).

As before, let $c_i = \pi^{-1}[\lambda_{2i-1}, \lambda_{2i}] \subset \mathcal{R}$ $(1 \leqslant i \leqslant g)$. The product $\tilde{D} = c_1 \times c_2 \times \cdots \times c_g$ is a real analytic g-torus which we view as an embedded submanifold of $\mathrm{Symm}^g(\mathcal{R}_0)$. The differential equations (4.99) define a one-parameter group of homeomorphisms $\{\tau_t\}$ on $\tilde{\Omega} \times \tilde{D}$, as follows: if $\tilde{\omega} \in \tilde{\Omega}$ and $\tilde{d} = (\tilde{P}_1, \ldots, \tilde{P}_g) \in \tilde{D}$, then

$$\tau_t(\tilde{\omega}, \tilde{d}) = \bigl(\tilde{\tau}_t(\tilde{\omega}), d(t)\bigr),$$

where $d(t) = \{P_1(t), \ldots, P_g(t)\}$ is obtained by solving (4.99) with initial value $\tilde{d}$.

Fix $\tilde{\omega} \in \tilde{\Omega}$, $\tilde{d} \in \tilde{D}$. Define a (positive) function $y(t)$ such that

$$2\sqrt{p(t)y(t)} = \frac{(-1)^{g+1}\mathcal{M}_1(t)\prod_{i=1}^{g} P_i(t)}{k(0^+)}. \tag{4.100}$$

Put

$$H(t,\lambda)=\prod_{i=1}^{g}\bigl[\lambda-\pi\bigl(P_i(t)\bigr)\bigr].$$

Consider the nonstandard Abel Jacobi coordinates (4.90). We repeat the computations after (4.90) with $\mathcal{M}_1(t)$ instead of $m_-^0(t)-m_+^0(t)$. The implicit dependence of $v_g(t)$ with respect to $v_0(t),\dots,v_{g-1}(t)$ is a general fact and does not depend on the particular choice of the surface and the points on it. Thus $v_g(t)$ is a transcendental function of $v_0(t),v_1(t)\dots,v_{g-1}(t)$ such that

$$\varsigma(t)=\sum_{i=1}^{g}\int_{P_*}^{P_i(t)}(v_0,v_1,\dots,v_g)\in\Upsilon,$$

or equivalently, $\Theta_0(C_0^{-1}\varsigma(t)-\Delta_0)=0$.

Let $D=I_0(\tilde{D})\subset\Upsilon$. We can identify $\tilde{\Omega}\times\tilde{D}$ with the product space $\tilde{\Omega}\times D\subset\tilde{\Omega}\times\Upsilon$. Let $(\tilde{\omega},\tilde{d})\in\tilde{\Omega}\times\tilde{D}$, then let

$$\Omega=\mathrm{cls}\left\{\left(\tilde{\tau}_t(\tilde{\omega}),I_0(0)+\left(\sum_{i=1}^{g}\int_{P_*}^{P_i(t)}(v_0,v_1,\dots,v_g)\right)\right)\,\middle|\,t\in\mathbb{R}\right\},$$

where $I_0(0)=(\sum_{i=1}^{g}\int_{P_*}^{P_i(0)}(v_0,v_1,\dots,v_g))$. The flow $(\tilde{\Omega}\times\tilde{D},\{\tau_t\})$ induces a flow on Ω which by abuse of notation we denote by $(\Omega,\{\tau_t\})$. Let $\tilde{\omega}\in\tilde{\Omega}$ be a point such that the orbit $\{\tilde{\tau}_t(\tilde{\omega})\mid\tilde{\omega}\in\tilde{\Omega}\}$ is dense in $\tilde{\Omega}$ (this holds for $\tilde{\nu}$-a.a. $\tilde{\omega}\in\tilde{\Omega}$), then let $\tilde{\pi}:\tilde{\Omega}\times\tilde{D}\to\tilde{\Omega}$ be the projection. The flow $(\Omega,\{\tau_t\})$ is an extension of the flow $(\tilde{\Omega},\{\tilde{\tau}_t\})$, in the sense that the projection $\tilde{\pi}$ restricted to Ω is a flow homeomorphism of Ω onto $\tilde{\Omega}$. There exists a $\{\tau_t\}$-ergodic measure ν on Ω which is the lift of the $\{\tilde{\tau}_t\}$-ergodic measure $\tilde{\nu}$ on $\tilde{\Omega}$, that is, $\tilde{\pi}(\nu)=\tilde{\nu}$. We give a short proof of this fact. First, we use the Birkhoff ergodic theorem together with a construction of Krylov–Bogoliubov type similar to that used in the proof of Lemma 4.18, to prove that the set $\mathcal{S}$ of all the $\{\tau_t\}$-invariant measures ι on Ω such that $\tilde{\pi}(\iota)=\tilde{\nu}$ is nonempty. Moreover, one can see that $\mathcal{S}$ is compact and convex in the weak-* topology. By the Krein–Mil'man theorem, $\mathcal{S}$ is the hull of its extreme points. It is easy to show that every extreme point ν of $\mathcal{S}$ is $\{\tau_t\}$-ergodic and projects into $\tilde{\nu}$.

If necessary, redefine Ω to be topological support of the measure ν: $\Omega=\operatorname{Supp}\nu$. Fix $\omega=(\tilde{\omega},d)\in\Omega$. Put

$$k_r(t)=k\bigl(P_r(t)\bigr),$$

and define a polynomial $Q(t,\lambda)$ of degree g in λ and with coefficients depending on t, such that

$$Q_i(t)=Q\bigl(t,\pi\bigl(P_i(t)\bigr)\bigr)=\sqrt{p(t)y(t)}\,k_i(t)\quad(i=1,\dots,g).\tag{4.101}$$

We also require that the highest term coefficient q_g is

$$q_g(t) = -\frac{(p(t)y(t))'}{4y(t)} \tag{4.102}$$

Define

$$M\big(d(t), P\big) = \frac{\sqrt{p(t)y(t)}\,k(P) + Q(t,\lambda)}{H(t,\lambda)}, \quad \lambda = \pi(P). \tag{4.103}$$

It is clear that

$$M\big(d(t), \sigma(P)\big) = \frac{Q(t,\lambda) - \sqrt{p(t)y(t)}\,k(P)}{H(t,\lambda)},$$

where σ is the hyperelliptic involution.

Define

$$h_+(t,P) = M\big(d(t), P\big) \quad \text{and} \quad h_-(t,P) = M\big(d(t), \sigma(P)\big), \tag{4.104}$$

and note that

$$h_+(t,0) - h_-(t,0) = -\mathcal{M}_1(t). \tag{4.105}$$

Put

$$\mathcal{M}_2(t) = h_+(t,0) + h_-(t,0) = \frac{2Q(t,0)}{H(t,0)}. \tag{4.106}$$

Finally, let

$$q(t) = y(t)\left(\sum_{i=0}^{2g} \lambda_i - 2\sum_{i=1}^{g} P_i(t)\right) + \frac{q_g^2(t)}{p(t)} + q_g'(t). \tag{4.107}$$

Corresponding to every $\omega \in \Omega \subset \tilde{\Omega} \times \Upsilon$, there is a one parameter family of matrices

$$\begin{pmatrix} 0 & 1/p(t) \\ q(t) - \lambda y(t) & 0 \end{pmatrix},$$

where y and q are defined as in (4.100) and (4.107) respectively.

We are ready to prove the following important result

THEOREM 4.52. *Let $\omega \in \Omega$, $\lambda = \pi^{-1}(P) \in \mathbb{C}$ with $\Im\lambda \neq 0$ and let $p(t), y(t)$ and $q(t)$ be continuous functions such that the relations* (4.100) *and* (4.107) *hold. Then $h_\pm(t,P)$ satisfy the Riccati equation*

$$h_\pm' + \frac{1}{p}h_\pm^2 = q - \lambda y. \tag{4.108}$$

PROOF. We will give the proof only for h_+. We want to prove that, differentiating (4.103) with respect to t, we obtain

$$\begin{aligned}&\big((\sqrt{py})'k + Q'\big)H - (\sqrt{py}\,k + Q)H' \\ &\quad + \frac{1}{p}(\sqrt{py}\,k + Q)^2 - (q - \lambda y)H^2 = 0. \end{aligned}\tag{4.109}$$

We rearrange (4.109) in the following way

$$\begin{aligned}&Q'H - QH' + yk^2 + \frac{1}{p}Q^2 - (q - \lambda y)H^2 \\ &\quad = k\bigg(\sqrt{py}H' - (\sqrt{py})'H - \frac{2}{p}\sqrt{py}Q\bigg). \end{aligned}\tag{4.110}$$

We claim that

$$\begin{aligned}F(t,\lambda) = \sqrt{p(t)y(t)}\,H'(t,\lambda) - \big(\sqrt{p(t)y(t)}\big)'H(t,\lambda) \\ - \frac{2}{p(t)}\sqrt{p(t)y(t)}\,Q(t,\lambda) = 0, \end{aligned}\tag{4.111}$$

Such a F is a polynomial in λ of degree g. It is easy to observe that $F(t,\lambda)$ has the points $\pi(P_i(t))$ as roots for every $i = 1,\dots,g$, hence it has g roots. Moreover the λ^g coefficient of $F(t,\lambda)$ is

$$-\big(\sqrt{p(t)y(t)}\big)' + \frac{2}{p(t)}\sqrt{p(t)y(t)}\,\frac{(p(t)y(t))'}{4y(t)} = 0,$$

hence $F(t,\lambda) = 0$. To conclude the proof, we examine the remaining term in (4.110), i.e.

$$\begin{aligned}L(t,\lambda) = Q'(t,\lambda)H(t,\lambda) - Q(t,\lambda)H'(t,\lambda) + y(t)k^2(P) \\ + \frac{1}{p(t)}Q^2(t,\lambda) - \big(q(t) - \lambda y(t)\big)H^2(t,\lambda), \quad \pi(P) = \lambda. \end{aligned}\tag{4.112}$$

$L(t,\lambda)$ is polynomial in λ of degree at most $2g+1$. It is easy to observe that for every $i = 1,\dots,g$, $\pi(P_i(t))$ is a root of $L(t,\lambda)$. As before we compute the coefficient α of λ^{2g+1} and β of λ^{2g}: we have

$$\alpha = y - y = 0$$

$$\beta = y(t)\Big(\sum\lambda_i - 2\sum P_i(t)\Big) + \frac{1}{p(t)}q_g^2(t) + q_g'(t) - q(t) = 0,$$

hence $L(t,\lambda)$ has degree at most $2g-1$. If we show that every $\pi(P_i(t))$ is a double root of $L(t,\lambda)$, then the proof is complete.

We observe that $H^2(t,\lambda)$ certainly has all the points $\pi(P_i(t))$ as double zeros, so we consider only

$$\begin{aligned} V(t,\lambda) &= Q'(t,\lambda)H(t,\lambda) - Q(t,\lambda)H'(t,\lambda) + y(t)k^2(P) \\ &\quad + \frac{1}{p(t)}Q^2(t,\lambda) = H(t,\lambda)N(t,\lambda), \quad \pi(P)=\lambda \end{aligned} \tag{4.113}$$

where

$$N(t,\lambda) = Q'(t,\lambda) - Q(t,\lambda)\frac{H'(t,\lambda)}{H(t,\lambda)} + y(t)\frac{k^2(P)}{H(t,\lambda)} + \frac{Q^2(t,\lambda)}{p(t)H(t,\lambda)}. \tag{4.114}$$

In view of the fact that $F(t,\lambda)=0$, we can write

$$H'(t,\lambda) = \frac{(p(t)y(t))'}{2p(t)y(t)}H(t,\lambda) + \frac{2}{p(t)}Q(t,\lambda) \tag{4.115}$$

and substituting this expression in (4.113) we have

$$\begin{aligned} V(t,\lambda) &= Q'(t,\lambda)H(t,\lambda) - Q(t,\lambda)\left(\frac{(p(t)y(t))'}{2p(t)y(t)}H(t,\lambda) + \frac{1}{p(t)}Q(t,\lambda)\right) \\ &\quad + y(t)k^2(P). \end{aligned} \tag{4.116}$$

Differentiating V with respect to t we have

$$\begin{aligned} V'(t,\lambda) &= Q''(t,\lambda)H(t,\lambda) + Q'(t,\lambda)H'(t,\lambda) \\ &\quad - Q'(t,\lambda)\left(\frac{(p(t)y(t))'}{2p(t)y(t)}H(t,\lambda) + \frac{1}{p(t)}Q(t,\lambda)\right) \\ &\quad - Q(t,\lambda)\left(\frac{(p(t)y(t))'}{2p(t)y(t)}H(t,\lambda) + \frac{1}{p(t)}Q(t,\lambda)\right)' + y'(t)k^2(P), \end{aligned} \tag{4.117}$$

and

$$\begin{aligned} V'(t,P_r) &= Q_r'(t)H_r'(t) - \frac{2}{p(t)}Q_r(t)Q_r'(t) - \frac{(p(t)y(t))'}{2p(t)y(t)}H_r'(t)Q_r(t) \\ &\quad + \frac{p'(t)}{p^2(t)}Q_r^2(t) + y'(t)k_r^2(t), \end{aligned} \tag{4.118}$$

since $H_r(t) = H(t,\pi(P_r(t))) = 0$.

Substituting in (4.118) the formulas for H_r' and Q_r obtained from (4.99), (4.100) and (4.101), we see that $V'(t,P_r)=0$, and we have proved that H divides $V' = HN' + H'N$, and so H divides $H'N$. Now, $H'(t, P_r) = -P_r'(t)\prod_{s\neq r}(P_r(t) - P_s(t))$, and $H_r'(t) = 0$ if and only if $P_r'(t) = 0$. If $P_r' \neq 0$ for every r then H divides N too, and the proof is complete.

Now, suppose that there is an index j and a value $\tilde{t} \in \mathbb{R}$ such that $P_j'(\tilde{t}) = 0$. In this case we must have necessarily $\sigma(P_j(\tilde{t})) = P_j(\tilde{t})$. In fact, if $\sigma(P_r(\tilde{t})) \neq P_r(\tilde{t})$ for every r, then we see that $P_r'(\tilde{t}) \neq 0$, since the (restricted) Abel map I_0 is a diffeomorphism of $\mathrm{Symm}^g(\mathcal{R}_0)$ onto Υ and π is invertible in a neighborhood of each P_r. If then $\sigma(P_j(\tilde{t})) = P_j(\tilde{t})$ for some $j \in \{1, \dots, g\}$ and $\tilde{t}$, we may approximate the divisor $d(\tilde{t})$ with an arbitrarily near divisor $d_\varepsilon(\tilde{t}) = P_{1,\varepsilon}(\tilde{t}) + \cdots + P_{g,\varepsilon}(\tilde{t})$ such that $\sigma(P_{r,\varepsilon}(\tilde{t})) \neq P_{r,\varepsilon}(\tilde{t})$ for every r. For this divisor, the conclusion of the proof above holds, and, passing to the limit, the same conclusion holds for $d(\tilde{t})$. The proof is complete. □

From Theorem 4.52 we obtain this important

THEOREM 4.53. *The real flow $(\Omega, \{\tau_t\})$ has the property that the spectrum of the family of two-dimensional nonautonomous differential systems of Sturm–Liouville type*

$$\begin{aligned}\begin{pmatrix} u \\ v \end{pmatrix}' &= \begin{pmatrix} 0 & \frac{1}{p(\omega\cdot t)} \\ q(\omega\cdot t) - \lambda y(\omega\cdot t) & 0 \end{pmatrix}\begin{pmatrix} u \\ v \end{pmatrix} \\ &= \omega(t,\lambda)\begin{pmatrix} u \\ v \end{pmatrix} \quad (\omega \in \Omega) \end{aligned} \tag{SL$_\omega$}$$

does not depend on the choice of $\omega \in \Omega$ and has the form

$$\Sigma(L) = [\lambda_0, \lambda_1] \cup [\lambda_2, \lambda_3] \cup \cdots \cup [\lambda_{2g}, \infty). \tag{4.119}$$

Moreover, $\beta(\lambda) = 0$, for all $\lambda \in \Sigma(L)$.

PROOF. For $\lambda \in \mathbb{C}$, define a flow $\{\hat{\tau}_t\}$ on $\Omega \times \mathbb{C}^2$ by setting

$$\hat{\tau}_t(\omega, u) = \big(\omega\cdot t, \Phi_\omega(t)u\big),$$

where, for every $\omega \in \Omega$, $\Phi_\omega(t)$ is the fundamental matrix solution for Eq. (SL$_\omega$) such that $\Phi_\omega(0) = \mathrm{Id}$. Clearly, this flow is induced on $\Omega \times \mathbb{P}(\mathbb{C})$ as well.

Given $\lambda \in \mathbb{C}$ with $\Im\lambda \neq 0$, let $P \in \pi^{-1}(\lambda)$ such that $\Im\lambda\Im k(P) > 0$; since $\omega = (\tilde{\omega}, d) \in \tilde{\Omega} \times \Upsilon$, define $m_+(\tilde{\omega}, d, \lambda) = M(d, P)$ and $m_-(\tilde{\omega}, d, \lambda) = M(d, \sigma(P))$.

By Theorem 4.52, both m_+ and m_- satisfy the Riccati equation (4.25), hence the sections

$$S^\pm(\lambda) = \big\{\big(\lambda, m_\pm(\tilde{\omega}, d, \lambda)\big) \mid (\tilde{\omega}, d) \in \Omega\big\} \subset \Omega \times \mathbb{P}(\mathbb{C})$$

are invariant under the flow $(\Sigma, \{\hat{\tau}_t\})$ for every λ with $\Im\lambda \neq 0$. By continuity, we can extend $S^\pm(\lambda)$ to the real line, keeping them still invariant, and hence we can define $m_\pm$ for every λ with $\Im\lambda = 0$.

Now, take $\lambda \in (\lambda_0, \lambda_1) \cup \cdots \cup (\lambda_{2g}, \infty)$; then it easy to observe that $\Im m_+(\tilde{\omega}, d, \lambda) > 0 > \Im m_-(\tilde{\omega}, d, \lambda)$. It follows that $S^+(\lambda)$ and $S^-(\lambda)$ are distinct. Clearly $\Omega \times \mathbb{P}(\mathbb{R})$ is invariant under the flow $(\Sigma, \{\hat{\tau}_t\})$. By using Liouville's formula, it is easy to show that every solution of (SL_ω) is bounded, for every $\omega \in \Omega$. Thus $\beta(\lambda) = 0$ and λ belongs to the spectrum of the full-line operator (SL_ω). On the other hand, if $\lambda \notin \Sigma(L)$, then the sections $S^{\pm}(\lambda)$ are real, hence the rotation number $\alpha(\lambda)$ of (SL_ω) is constant. It is clear that the only possibility is that λ belongs to the resolvent set (in fact equations (SL_ω) admit an exponential dichotomy; see Theorem 4.21(iii)).

Thus we proved that the spectrum has the form $\Sigma(L) = [\lambda_0, \lambda_1] \cup \cdots \cup [\lambda_{2g}, \infty)$ for every $\omega \in \Omega$, and that $\beta(\lambda) = 0$ for all $\lambda \in \Sigma(L)$. □

A more detailed study of the flow $(\Omega, \{\tau_t\})$ has been carried out in [95]. It is possible to obtain more information concerning the structure of the flow $(\Omega, \{\tau_t\})$ if the set of endpoints of the intervals which determine the spectrum $\Sigma(L)$ satisfy a certain condition, namely that if $\mathcal{R}$ is the Riemann surface of the algebraic relation $w^2 = -(\lambda - \lambda_0)(\lambda - \lambda_1) \cdots (\lambda - \lambda_{2g})$ and $c_i = \pi^{-1}([\lambda_{2i-1}, \lambda_{2i}])$ $(i = 1, \dots, g)$, then the vectors $\zeta_i = \int_{c_i} (v_0, \dots, v_{g-1})$ $(i = 1, \dots, g)$ are linearly independent in $\mathbb{R}^g$. This condition is satisfied in an open dense subset of the space of endpoints, and there are examples for which the above condition is not fulfilled, at least when g is odd. In any case, if the above condition is satisfied, then one can show that for "almost" every pair of functions $(p(t), \mathcal{M}(t))$, the flow $(\Omega, \{\tau_t\})$ generated by $(p, \mathcal{M})$ laminates into closed subsets Ω_h, where h varies in a quotient group $\mathcal{H}$ of the g-torus. Moreover, each set Ω_h is the topological support of an ergodic measure ν_h on Ω. It turns out that, in general, it is difficult to actually determine $\mathcal{H}$, and hence an exact parametrization of the sets Ω_h. However, if $p(t)$ and $\mathcal{M}(t)$ are Bohr almost periodic, then it is possible to determine the "size" of the quotient group $\mathcal{H}$ by looking at the frequency module of the hull of the pair $(p, \mathcal{M})$ (see [95] for more information on this topic).

5. Genericity of exponential dichotomy

As was stated in Section 1, we will consider the question of the genericity of the exponential dichotomy property for cocycles generated by quasi -periodic, two-dimensional linear systems. Thus, we will consider minimal quasi-periodic flows of Kronecker-type generated on the torus $\mathbb{T}^k$ by a vector of frequencies γ, where $\gamma \in \Gamma \subset \mathbb{R}^k$, the set of frequencies whose components are rationally independent. To be precise we study the minimal flow $\{\tau_t\}$ on $\mathbb{T}^k$ given by $\tau_t(\psi) = \psi + \gamma t$ where $\psi = (\psi_1, \dots, \psi_k) \in \mathbb{T}^k$ and $\gamma = (\gamma_1, \dots, \gamma_k) \in \Gamma$. Let us agree to abbreviate exponential dichotomy by E.D. We have that, by the robustness properties of the E.D. (see [29,130]), the set $\mathcal{C}_{\mathrm{ED}} = \{A \in C_0 \mid$ the family of systems $x' = A(\tau_t(\psi))x$ $(\psi \in \mathbb{T}^k)$ admits an E.D.$\}$ is open in the corresponding topology. Here recall that C_0 is the set defined by $C_0 = \{A : \mathbb{T}^k \to \mathrm{sl}(2, \mathbb{R}) \mid A$ is continuous$\}$ in which we consider the sup norm $\|A\| = \sup_{\psi \in \mathbb{T}^k} |A(\psi)|$, where in turn $|\cdot|$ is the sup norm on $\mathrm{sl}(2, \mathbb{R})$ given by $|B| = \sup\{|Bx|_{\mathbb{R}^2}$ with $|x|_{\mathbb{R}^2} = 1\}$. What we will show is the density of the set $\mathcal{C}_{\mathrm{ED}}$ for a residual subset of frequencies $\gamma \in \Gamma$. It will be apparent from the proof that these frequencies are of "Liouville-type". By this we mean rather vaguely that the frequencies are "sufficiently close" to rational numbers; the result we discuss below gives no estimate on the degree of "closeness".

Let $\mathcal{D} = \{(\gamma, A) \in \mathbb{R}^k \times C_0 \mid \text{ the system } x' = A(\tau_t(\psi))x \text{ admits an E.D. over } \mathbb{T}^k\}$. We will prove that the set $\mathcal{D}$ is open and dense in $\mathbb{R}^k \times C_0$. We have already observed that the set $\mathcal{C}_{\mathrm{ED}}$ is open. That $\mathcal{D}$ is open is a consequence of a theorem of Sacker and Sell [137] which is a variant of the results concerning roughness of exponential dichotomies mentioned above [29,130]. What is of interest here is the density result. If we fix a frequency $\gamma \in \Gamma$, we could ask if the set $\mathcal{D}_\gamma = \{A \in C_0 \mid \text{ the system } x' = A(\tau_t(\psi))x \text{ admits an E.D. over } \mathbb{T}^k\}$ is open and dense in C_0. While the openness follows from [29] (also [130,137]), we have that the density of $\mathcal{D}_\gamma$ cannot be proved for all $\gamma \in \Gamma$, but only for a residual set of frequencies.

We will state and prove the exact result below; before doing so, recall that in the Introduction we already noted that if we consider as a compact metric space Ω the circle and as the flow the periodic flow given by the rigid rotation on the circle, we have that the density fails to hold. There are also some other examples in which the density property fails, depending on the topology of the compact metric space Ω and on the nature of the flow (see [75]).

The main result of this section is the following:

THEOREM 5.1. *Consider the set* $\mathcal{D} = \{(\gamma, A) \in \mathbb{R}^k \times C_0 \mid$ *the system* $x' = A(\tau_t(\psi))x$ *admits an E.D. over* $\mathbb{T}^k\}$. *Then the set* $\mathcal{D}$ *is open and dense in* $\mathbb{R}^k \times C_0$.

We have said that the openness of the set $\mathcal{D}$ in $\mathbb{R}^k \times C_0$ follows from a theorem of Sacker and Sell [137] which we will state in a form convenient for our purposes in Theorem 5.3 below. To prove the density we will proceed by contradiction: supposing that there is an open set $V \subset \mathbb{R}^k \times C_0$ such that, if $(\gamma, A) \in V$, then the corresponding family of systems does not have an E.D. over $\mathbb{T}^k$, we will arrive at a contradiction.

We will give the scheme of the proof of this fact. Before doing so, we recall here some general facts about the properties of the rotation number and the Lyapunov exponent of the systems considered. Consider then the family of equations

$$x' = A\bigl(\tau_t(\psi)\bigr)x, \quad x \in \mathbb{R}^2 \tag{5.1}$$

where $t \in \mathbb{R}$, $\psi \in \mathbb{T}^k$, $\tau_t(\psi) = \psi + \gamma t$, $\gamma \in \mathbb{R}^k$ and $A \in C_0$. We can write the coefficient matrix as

$$A = \begin{pmatrix} a & -b+c \\ b+c & -a \end{pmatrix}$$

where $a, b, c : \mathbb{T}^k \to \mathbb{R}$ are continuous functions. As already explained in Section 2, after passing to polar coordinates (r, θ), we can define the rotation number $\alpha = \alpha(\psi, \gamma, A)$ as the following limit

$$\alpha = \lim_{t \to \infty} \frac{\theta(t)}{t}$$

where θ is the solution of the equation for the polar angle given by

$$\theta' = b(\psi \cdot t) - a(\psi \cdot t)\sin 2\theta + c(\psi \cdot t)\cos 2\theta$$

where we set $\psi \cdot t = \psi + \gamma t$. If we consider a vector of frequencies $\gamma \in \Gamma$, we have that the limit defining α exists and depends neither on the choice of the initial value $\theta(0)$ nor on the choice of the element $\psi \in \mathbb{T}^k$ ([89] and Theorem 4.19). On the other hand, if we take a frequency vector $\gamma \notin \Gamma$, that is a vector whose components satisfy linear relations with coefficients in $\mathbb{Q}$, then the rotation number does not depend on the initial value $\theta(0)$, but may depend on $\psi \in \mathbb{T}^k$. In this case we have that the rotation number is constant on the closure of the orbit passing through ψ, for each $\psi \in \mathbb{T}^k$.

As already mentioned the rotation number has good continuity properties which we now discuss and which will be useful in the proof of the result. If we fix a vector of frequencies $\gamma \in \mathbb{R}^k$, then using the basic Krylov–Bogoliubov method for the construction of invariant measures, one can prove that α is "very" continuous when the matrix A varies. In fact, consider a topological space $\mathcal{E}$ and a continuous map $\mathcal{E} \to C_0$: $E \mapsto A_E$. We have then that $(\psi, E) \mapsto \alpha(\psi, A_E) : \mathbb{T}^k \times \mathcal{E} \to \mathbb{R}$ is jointly continuous with respect to $\psi \in \mathbb{T}^k$ and $E \in \mathcal{E}$. Moreover, there is a sort of continuity with respect to the frequency: suppose that $\gamma \in \Gamma$, and consider a sequence of frequencies $\{\gamma_n\} \subset \mathbb{R}^k$ such that $\gamma_n \to \gamma$ as $n \to \infty$. Observe that it is not required that γ_n belongs to Γ. Then one has, considering a continuous map $E \mapsto A_E$: $\mathcal{E} \to C_0$, that

$$\alpha(\psi, \gamma_n, A_E) \to \alpha(\psi, \gamma, A_E) \equiv \alpha(\psi, A_E) \tag{5.2}$$

when the convergence is uniform on compact subsets of $\mathbb{T}^k \times \mathcal{E}$. Observe that the last equality follows from the fact that, when $\gamma \in \Gamma$, α does not depend on the frequency. The convergence (5.2) can be proved using the Krylov–Bogoliubov method already mentioned. See [113] and [89].

The following theorem relates the presence of an E.D. for a (real) perturbation of the family (5.1) to the monotonicity of the rotation number.

THEOREM 5.2. *Let $A \in C_0$ and consider the family of equations*

$$x' = \left[A\left(\tau_t(\psi)\right) + JE\right]x \tag{5.3}$$

where $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, $E \in \mathbb{R}$ and $\psi \in \mathbb{T}^k$. Let $I = (E_1, E_2) \subset \mathbb{R}$ be an open interval. Suppose that $\gamma \in \Gamma$, then the family of Eqs. (5.3) *admits an E.D. over $\mathbb{T}^k$ for all $E \in I$ if and only if the rotation number $\alpha(E)$ is constant on I.*

The proof of the theorem can be found in [59]; see Theorem 4.21. Remember that the rotation number also depends on the ergodic measure defined in our compact metric space, which in the present case is the normalized Lebesgue measure on $\mathbb{T}^k$.

The rotation number of Eq. (5.3), for E fixed and $\psi \in \mathbb{T}^k$, defines a function $E \to \alpha(E)$ which is a monotone, nondecreasing nonnegative function which increases exactly on the spectrum of the corresponding linear operator $L_\psi := J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - A(\tau_t(\psi))]$ for each $\psi \in \mathbb{T}^k$. This operator, called the AKNS operator, is viewed as un unbounded self-adjoint operator on the Hilbert space $L^2(\mathbb{R}, \mathbb{C}^2)$. There is an important relation between the dichotomy property and the spectral properties of the operator L_ψ: a complex number E belongs to the resolvent of the operator L_ψ if and only if the corresponding differential system

$x' = [A(\tau_t(\psi)) + JE]x$ admits an E.D. See [79,59] and Proposition 4.15 together with the succeeding discussion.

In the proof of Theorem 5.1, we will perturb our family of equations and arrive at a family of periodic systems. For this reason we recall here some facts and properties of periodic ordinary differential operators which we will use later.

Consider a summable function $a:[0,T) \to \mathrm{sl}(2,\mathbb{R})$; we can view $a(\cdot)$ as a T-periodic function on the whole real axis by extending it in the natural way. Consider then the corresponding periodic differential operator $L = J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - a(t)]$ on the space $L^2(\mathbb{R},\mathbb{C}^2)$. Using Floquet theory and extending the arguments of [104], one can obtain the following facts:

1) The spectrum Σ of the self-adjoint operator L is a union (finite or countably infinite) of nondegenerate closed intervals.
2) Consider the rotation number $\alpha(E)$ of the periodic system $x' = [a(t) + JE]x$. Let $I \subset \mathbb{R}$ be a resolvent interval of L; i.e., I is a maximal subinterval of $\mathbb{R} \setminus \Sigma$. Then there exists a unique integer l such that $E \in \operatorname{cls} I$ if and only if $\alpha(E) = \frac{\pi l}{T}$, in particular $\alpha(E)$ is a integer multiple of $\frac{\pi}{T}$.
3) Let $\Phi_E(T)$ be the period matrix of the system $x' = [a(t) + JE]x$ and let $I \subset \mathbb{R}$ be a resolvent interval of L. We have then that for each $E \in I$, there are two linearly independent real eigenvectors $v_\pm$ of $\Phi_E(T)$. (We refer to this as the hyperbolic case). If $\alpha(E) = \frac{2\pi m}{T}$, that is, l is even, with $l = 2m$, $m \in \mathbb{Z}$, then the corresponding eigenvalues $B_\pm$ verify $0 < B_- < 1 < B_+$.

   If E is an endpoint of the interval I, then-up to constant multiple- $\Phi_E(T)$ admits a unique eigenvector v.The corresponding eigenvalue is -1 if the integer l is odd, and is $+1$ if l is even. We refer to this as the parabolic case.
4) Consider E in the interior of the spectrum Σ such that $\alpha(E) = \frac{\pi l}{T}$ for $l \in \mathbb{Z}$. Then we have that $\Phi_E(T) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}$ if l is odd, while $\Phi_E(T) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ if $l = 2m$ is even. In either case we say that E defines a *closed gap* of L. We refer to this as the elliptic case.
5) Consider a sequence $\{a_n\}$ of T-periodic, $\mathrm{sl}(2,\mathbb{R})$-valued functions such that $\int_0^T |a_n(s) - a(s)|\,\mathrm{d}s \to 0$ as $n \to \infty$. Suppose also that I_n and I are resolvent intervals of the corresponding periodic operators L_n and L where $L_n = J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - a_n(t)]$ and $L = J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - a(t)]$. Let α_n be the rotation number associated to the operator L_n and suppose that $\alpha(E) = \frac{\pi l}{T}$ if $E \in I$ and $\alpha_n(E) = \frac{\pi l}{T}$ if $E \in I_n$ where l is a fixed integer and $n = 1, 2, \ldots$. Then $I_n \to I$, in the sense that the sequences of endpoints of I_n converge to the endpoints of I, and moreover one has the following result. Let $I_n = (b_n, c_n)$ be a resolvent interval for each $n \geqslant 1$, and suppose that $\overline{E}$ defines a closed gap of the operator L. Suppose also that $\alpha(\overline{E}) = \frac{\pi l}{T} = \alpha_n(E)$ where $E \in I_n, n = 1, 2, \ldots$. Then $b_n \to \overline{E}$ and $c_n \to \overline{E}$ as $n \to \infty$.

Before passing to the proof of Theorem 5.1, we recall some facts about the upper Lyapunov exponent $\beta = \beta(\psi, A)$ of the family of equations $x' = A(\psi + \gamma t)x$. This object is defined by

$$\beta = \lim_{t\to\infty} \frac{1}{t} \log \bigl\| \Phi_\psi(t) \bigr\| \tag{5.4}$$

where $\Phi_\psi(t)$ is the fundamental matrix of the equation defined by $\psi \in \mathbb{T}^k$. It is known that, if $\gamma \in \Gamma$, the limit (5.4) exists and takes on a constant value for Lebesgue-a.a. $\psi \in \mathbb{T}^k$. For fixed $A \in C_0$, if the vector of frequencies $\gamma \in \mathbb{Q}^k$, then the limit defining β exists for all $\psi \in \mathbb{T}^k$ and the function $\psi \to \beta(\psi)$ is continuous. This follows from Floquet theory for periodic systems (remember that $\gamma \in \mathbb{Q}^k$). On the other hand, if $\gamma \notin \mathbb{Q}^k$, the limit (5.4) need not exist for *all* $\psi \in \mathbb{T}^k$. So, when we consider the frequency vector $\gamma \in \Gamma$, we refer to this a.e.-constant limit as the upper Lyapunov exponent of the family $x' = A(\psi + \gamma t)x$. Moreover, β is an upper semi-continuous function. More precisely, let $\mathcal{E}$ be a topological space, and let $E \to A_E; \mathcal{E} \to C_0$ be a continuous function. Let $\gamma \in \Gamma$; then the function $E \to \beta(A_E)$ is upper semi-continuous, but is not in general continuous. In our case $A(\cdot) \in \mathrm{sl}(2,\mathbb{R})$, and therefore we have two "ordinary" Lyapunov exponents $\beta_1 = -\beta_2$ with $\beta_2 \geqslant 0$, and $\beta = \beta_2$.

We recall now the robustness properties of the E.D. in a form convenient for our case. Consider the space $\mathcal{L} = L^\infty(\mathbb{R}, \mathrm{sl}(2,\mathbb{R}))$ and consider the weak-* topology in $\mathcal{L}$: a generalized sequence $\{A_n\}$ converges to A in $\mathcal{L}$ if and only if

$$\int_{-\infty}^{\infty} A_n(t)\varphi(t)\,\mathrm{d}t \to \int_{-\infty}^{\infty} A(t)\varphi(t), \quad \forall \varphi \in L^1(\mathbb{R}).$$

By the Alaoglu theorem, norm-bounded subsets of the space $\mathcal{L}$ are precompact in the weak-* topology (they are also metrizable), so, when we consider the hull of $A \in \mathcal{L}$ given by $Y = \mathrm{cls}\{A_s(\cdot) \mid s \in \mathbb{R}\}$ where $A_s(\cdot) = A(\cdot + s)$ is the translation with respect to the time, we obtain a compact and time-translation invariant subset of $\mathcal{L}$. Observe that there is no need to restrict attention to weak-* compact, translation invariant sets Y which are the hull of some $A \in \mathcal{L}$, but rather we can consider Y to be any weak-* compact, translation invariant subset of $\mathcal{L}$.

Now we state the robustness properties of the E.D. concept as follows. Suppose that the family of equations

$$x' = y(t)x, \quad y \in Y \tag{5.5}$$

admits an E.D. over the compact set Y. According the definition this means that there exist constants $c, \eta > 0$ and a projection valued function $P = P_y : Y \to \mathrm{Proj}(\mathbb{R}^2)$ where $\mathrm{Proj}(\mathbb{R}^2) = \{Q \in \mathbb{M}_2 \mid Q^2 = Q\}$, such that, if $\Phi_y(t)$ is the fundamental matrix solution of (5.5), then the following inequalities hold:

$$\begin{aligned}
&\left\|\Phi_y(t)P_y\Phi_y(s)^{-1}\right\| \leqslant c\mathrm{e}^{-\eta(t-s)}, \quad t \geqslant s, \\
&\left\|\Phi_y(t)(I - P_y)\Phi_y(s)^{-1}\right\| \leqslant c\mathrm{e}^{\eta(t-s)}, \quad t \leqslant s.
\end{aligned}$$

The perturbation theorem for the E.D. [137] states the following

THEOREM 5.3. *Let $Y_0 \subset \mathcal{L}$ a fixed norm-bounded weak-* compact, translation invariant set. Let $Y \subset Y_0$ be a weak-* compact, translation invariant set such that Eqs.* (5.5) *admit* *an E.D. over Y. There exists a weak-* neighborhood U of Y in Y_0 so that, if $\tilde{Y} \subset U$ is another weak-* compact and translation invariant set, then the corresponding Eqs.* (5.5) *have an E.D. over $\tilde{Y}$.*

Observe that we consider neighborhoods with respect to a distance defined by a metric compatible with the weak-* topology considered in the space $Y_0 \subset \mathcal{L}$.

From Theorem 5.3 there follows the openness in $\mathbb{R}^k \times C_0$ of the set $\{(\gamma, A) \in \mathbb{R}^k \times C_0 \mid x' = A(\psi + \gamma t)x$ has an E.D. over $\mathbb{T}^k\}$. See [44] for more details.

5.1. *Proof of Theorem 5.1 (Density result)*

In this subsection we will sketch the proof of Theorem 5.1; as already mentioned, the proof is a fairly lengthy argument by contradiction. We start from the following

HYPOTHESIS 5.4. There exists an open subset $V \subset \mathbb{R}^k \times C_0$ such that, if the pair $(\gamma, A) \in V$, then the corresponding differential system

$$x' = A(\psi + \gamma t)x$$

does not have an E.D. over $\mathbb{T}^k$.

Remember that, if the frequency vector $\gamma \in \Gamma$, Hypothesis 5.4 means that E.D. fails for *all* $\psi \in \mathbb{T}^k$. If the vector $\gamma \in \mathbb{R}^k \setminus \Gamma$, Hypothesis 5.4 means that for at least one point $\psi \in \mathbb{T}^k$ the E. D. property does not hold. Further, if there is no E.D. for (at least) one point $\psi \in \mathbb{T}^k$, then E.D. fails to hold for each point in the orbit closure $\mathrm{cls}\{\tau_t(\psi) \mid t \in \mathbb{R}\}$ of the point as well.

We can consider w.l.g. an open set $V \subset \mathbb{R}^k \times C_0$ of the following type: $V = V_1 \times V_2$ where $V_1 \subset \mathbb{R}^k$ and $V_2 \subset C_0$ are open sets. Consider now $\Gamma_1 = \Gamma \cap V_1$. Using a result of [44], see Theorem 5.5 below, we have that there exists a residual subset W_* of $\Gamma_1 \times C_0$ such that, if the pair $(\gamma, A) \in W_*$, then the Lyapunov exponent $\beta(\gamma, A)$ of the corresponding family $x' = A(\psi + \gamma t)x$ equals zero. Let us note that there are recent results of Bochi and Viana [19] which generalize this statement; for our purposes the result of [44] is quite sufficient.

Recall here that the presence of an E.D. for a family of equations implies that the corresponding Lyapunov exponent is positive, but that the positivity of the Lyapunov exponent is not enough to guarantee the presence of an E.D. The exact result (here we are considering the continuous case) proved in [44] is the following

THEOREM 5.5. *Suppose that* $0 \leqslant r < 1$ *where* $r \in \mathbb{R}$ *and let* $C^r = C^r(\mathbb{T}^k, \mathrm{sl}(2, \mathbb{R}))$ *be the set of C^r- mappings from $\mathbb{T}^k$ to* $\mathrm{sl}(2, \mathbb{R})$ *with the usual topology. There is a residual subset W_* of $\Gamma \times C^r$ with the following property*: *if $w = (\gamma, A) \in W_*$, then either equations $x' = A(\psi + \gamma t)x$ admit an E.D. or the Lyapunov exponent $\beta(w)$ equals zero.*

According to Theorem 5.5, we can then find a frequency $\gamma_* \in \Gamma \cap V_1$ and a function $A_* \in V_2$, such that the corresponding Lyapunov exponent $\beta(\gamma_*, A_*)$ equals zero. From now on we fix γ_* and A_*. What we are going to do now is to perturb the frequencies of our system of equations to obtain a certain rational frequency vector and a corresponding family of periodic linear systems. It is a fact that the Lyapunov exponent $\beta = \beta(\gamma, A)$ is a semicontinuous function with respect to the coefficient matrix A and with respect to various topologies; in the proof we apply the following result. For a proof we refer to [44].

LEMMA 5.6. *Consider the sequence* $\{\gamma_n\} \subset \mathbb{Q}^k$ *of frequency vectors with rationally dependent components such that* $\gamma_n \to \gamma_*$. *Let* $A_n \to A_*$ *as* $n \to \infty$ *in* C_0. *Indicate with* $\beta(\psi, \gamma_n, A_n)$ *the Lyapunov exponent of the periodic system* $x' = A_n(\psi + \gamma_n t)x$. *Then* $\beta(\psi, \gamma_n, A_n) \to \beta(\gamma_*, A_*) = 0$ *where the convergence is uniform with respect to* $\psi \in \mathbb{T}^k$.

After these considerations and remarks we can proceed with the proof of Theorem 5.1; we are considering a pair $(\gamma_*, A_*) \in \Gamma_1 \times V_2$ such that the corresponding system does not have an E.D. and the related Lyapunov exponent $\beta(\gamma_*, A_*) = 0$. Consider now the family of equations

$$x' = \left[A_*(\psi + \gamma_* t) + JE\right]x, \quad E \in \mathbb{R},$$

and its corresponding rotation number $\alpha_*(E)$; we have then that the function $E \to \alpha_*(E)$ is continuous and it strictly increases at $E = 0$ by the monotonicity of the rotation number and by the fact that for $E = 0$ there is no E.D. There exists $E_0 > 0$ such that, if $|E| < 2E_0$, then $A_* + JE \in V_2$. The rotation number is strictly increasing at $E = 0$: precisely, for each $\delta > 0$, $\alpha(\delta) - \alpha(0) > 0$ and $\alpha(0) - \alpha(-\delta) > 0$.

Now, let $\gamma_n \in \mathbb{Q}^k$ be a sequence of frequency vectors with rational coefficients such that $\gamma_n \to \gamma_*$. We choose $\gamma_n = (\frac{p_1^{(n)}}{q_1^{(n)}}, \dots, \frac{p_k^{(n)}}{q_k^{(n)}})$ and require that each pair $q_i^{(n)}$, $q_j^{(n)}$ of denominators be relatively prime for $1 \leqslant i < j \leqslant k$. This condition implies that, if $T_n = q_1^{(n)} q_2^{(n)} \cdots q_k^{(n)}$, then the flow $\psi + \gamma_n t$ is T_n-periodic. Let $\rho > 0$ a positive number. As proved in [77] (see also [44] and [45]) it is the case that there exists a number $N_0 \geqslant 1$ such that, to each $n \geqslant N_0$, there correspond an integer m and a continuous function $E_n : \mathbb{T}^k \to \mathbb{R}$ such that

(i) The function E_n is constant along each γ_n-orbit, that is

$$E_n(\psi) = E_n(\psi + \gamma_n t) \quad (\psi \in \mathbb{T}^k, 0 \leqslant t \leqslant T_n).$$

(ii) $\|E_n\| < \rho$.

(iii) The rotation number $\alpha_n(\psi)$ of the periodic system

$$x' = \left[A_*(\psi + \gamma_n t) + JE_n(\psi)\right]x \tag{5.6}$$

satisfies

$$\alpha_n(\psi) = \frac{2\pi m}{T_n} \quad (\psi \in \mathbb{T}^k).$$

We obtain E_n by using the monotonicity and continuity properties of the rotation number to arrive to a family of T_n-periodic systems for which the rotation number is an even multiple of $\frac{\pi}{T_n}$. In this case, according to the discussion made in the previous subsection for the periodic differential operator L associated to a T-periodic function with value in the algebra $\mathrm{sl}(2, \mathbb{R})$, only two situations may occur (remember that we are imposing Hypothesis 5.4, so E.D. does not hold over $\mathbb{T}^k$ in the open set $V \subset \mathbb{R}^k \times C_0$).

- If the (periodic) operator $L_\psi = J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - A_*(\psi + \gamma_n t)]$ admits a resolvent interval I_ψ wherein the rotation number $\alpha(\psi, \gamma_n, A_* + JE)$ has value $\frac{2\pi m}{T_n}$, then define $E_n(\psi)$ to be the center point of I_ψ.
- If on the other hand there is a number $E_0 \in \mathbb{R}$ which defines a closed gap of L_ψ with $\alpha(\psi, \gamma_n, A_* + JE_0) = \frac{2\pi m}{T_n}$, then set $E_n(\psi) = E_0$. One verifies that E_n is continuous.

Now we continue discussing the proof of Theorem 5.1. Choose a positive number ρ in such a way that the ball in C_0 of center A_* and radius ρ is contained in the open set V_2. Moreover determine N_0, $n \geqslant N_0$, m and E_n as above (for the construction of them see the discussion in [44]) and let $\psi^0 = (0, 0, \dots, 0)$ be the origin of $\mathbb{T}^k$ with respect to the angular coordinates $(\psi_1, \dots, \psi_k)$. Write $\bar{A}(\psi) = A_*(\psi) + JE_n(\psi)$ $(\psi \in \mathbb{T}^k)$, so that $\bar{A}(\psi) \in V_2$ and for the corresponding periodic system of equations $x' = \bar{A}(\psi + \gamma_n t)x$ E.D. does not hold over $\mathbb{T}^k$, and the corresponding rotation number is given by $\alpha(\psi, \gamma_n, \bar{A}) = \frac{2\pi m}{T_n}$. Adapting a method of Moser [110], as done in [45], we find an $A_0 \in C_0$ with $\|A_0 - A_*\| < \rho$ and such that the corresponding system along the orbit of ψ^0 with frequency γ_n has an E.D. (e.g. such that the system $x' = A_0(\psi^0 + \gamma_n t)x$ admits an E.D.).

We discuss in more detail the method of Moser. Observe that the condition $\alpha(\psi, \gamma_n, \bar{A}) = \frac{2\pi m}{T_n}$ induces a restriction on the behavior of the period matrix $\Phi_\psi(T_n)$ of the (periodic) system $x' = \bar{A}(\psi + \gamma_n t)x$. We reformulate this restriction geometrically: we have already listed, in the previous section , the relations between the rotation number and the spectral properties of a T-periodic differential operator (see (1), …, (5) on page 253). The facts that the rotation number $\alpha(\psi, \gamma_n, \bar{A}) = \frac{2\pi m}{T_n}$ and the absence of an E.D. for the corresponding periodic system $x' = \bar{A}(\psi + \gamma_n t)x$, imply that $\Phi_\psi(T_n)$ verifies one of the following conditions:

(i) $\Phi_\psi(T_n) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, the identity matrix. This is the elliptic case.

(ii) $\Phi_\psi(T_n)$ has eigenvalue 1 and a unique one-dimensional eigenspace (parabolic case).

We cannot have the hyperbolic case because the system does not admit an E.D. Geometrically these conditions mean that the logarithm of the periodic matrix solution $\Phi_\psi(T_n)$ lies on the surface of a certain cone C whose construction was made and used in [111] for the study of the quasi-periodic Schrödinger operator. Introduce then the following cone C: observe that each matrix $A \in \mathrm{sl}(2, \mathbb{R})$ can be written in the form $\left(\begin{smallmatrix} a & b-c \\ b+c & -a \end{smallmatrix}\right)$ where a, b, c are real numbers. Let C defined by the set $\{(a, b, c) \in \mathbb{R}^3 \mid c^2 = a^2 + b^2\}$, then C is just the set of matrices A which admit zero as an eigenvalue. We of course identify the triple $(a, b, c) \in \mathbb{R}^3$ with the matrix $\left(\begin{smallmatrix} a & b-c \\ b+c & -a \end{smallmatrix}\right)$. Now, let $D_* \subset \mathrm{SL}(2, \mathbb{R})$ be the set of all matrices Φ which are parabolic, or hyperbolic and have positive eigenvalues. There is an open set $D \subset \mathrm{SL}(2, \mathbb{R})$ which contains D_* and a single-valued, real-analytic branch $\ln : D \to \mathrm{sl}(2, \mathbb{R})$ of the matrix logarithm such that $\ln I = \ln\left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. Moreover $\ln(D)$ contains the cone C and its exterior $\{(a, b, c) \mid a^2 + b^2 > c^2\}$. Writing this fact in terms of the T-period matrix solution $\Phi_\psi(T)$ one has immediately that:

$\Phi_\psi(T)$ is elliptic if and only if $\ln\Phi_\psi(T) = (0,0,0)$;

$\Phi_\psi(T)$ is parabolic if and only if $\ln\Phi_\psi(T)$ lies on the surface of the cone C but is not the vertex $(0,0,0)$;

$\Phi_\psi(T)$ is hyperbolic if and only if $\ln\Phi_\psi(T)$ lies outside the cone C.

We have thus that in our case the logarithm $\ln\Phi_\psi(T_n)$ of the period matrix solution $\Phi_\psi(T_n)$ of the periodic system $x' = \bar{A}(\psi + \gamma_n t)x$ lies on the surface of the cone C. It is now intuitively reasonable that we can perturb A to a matrix function $A_0 \in C_0$ such that $x' = A_0(\psi^0 + \gamma_n t)x$ has an E.D. See [43] and [44] for details.

Let us write $\gamma = \gamma_n$ and then consider the rational frequency vector $\gamma = (\frac{p_1}{q_1}, \dots, \frac{p_k}{q_k})$ for which the properties (i)–(iii) hold. Recall also that each pair q_i, q_j is relatively prime ($1 \leqslant i < j \leqslant k$). The proof of Theorem 5.1 now proceeds as follows. We extend A_0 along the various faces of a "quasi-section" $S \subset \mathbb{T}^k$ to the linear flow on $\mathbb{T}^k$ with frequency vector γ. In the end we obtain a function $A \in C_0$ with $\|A - A_*\| < \rho$ and such that $x' = A(\psi + \gamma t)x$ has an E.D. for all $\psi \in S$ and hence – by the choice of S – for all $\psi \in \mathbb{T}^k$. The presence of an E.D. contradicts the Hypothesis 5.4 and thus Theorem 5.1 is proved.

Let us explain briefly the construction of the "quasi-section" S. Let S be the following set: $S = \{\psi = (\psi_1, \dots, \psi_k) \in \mathbb{T}^k \mid \psi_k = 0 \text{ and } 0 \leqslant \psi_i \leqslant \frac{2\pi}{q_i} (1 \leqslant i \leqslant k-1)\}$. (Recall that $\psi_1, \dots, \psi_k$ are angular coordinates mod 2π on $\mathbb{T}^k$). Observe that the S lies in the hyperplane $\{\psi \in \mathbb{T}^k \mid \psi_k = 0\}$ and that $\psi^0 = (0, 0, \dots, 0)$ is one of its vertices. Moreover $S = \bigcup_{p=0}^{k-1} S_p$ where S_p is the union of all p-dimensional faces of S where each face is a p-dimensional rectangle.

If $k = 2$, the quasi-section S is simply the segment

$$S = \left\{ (\psi_1, \psi_2) \in \mathbb{T}^2 \;\middle|\; 0 \leqslant \psi_1 \leqslant \frac{2\pi}{q_1}, \psi_2 = 0 \right\}$$

and for $k = 3$ the quasi-section S is the rectangle

$$S = \left\{ (\psi_1, \psi_2, \psi_3) \in \mathbb{T}^3 \;\middle|\; 0 \leqslant \psi_1 \leqslant \frac{2\pi}{q_1}, 0 \leqslant \psi_2 \leqslant \frac{2\pi}{q_2}, \psi_3 = 0 \right\}$$

in the ψ_1–ψ_2 plane. We can thus consider $\psi^0 = (0,0,0)$ as the lower-left hand vertex of the rectangle S.

Moreover observe that, if $\psi \in \mathbb{T}^k$, then its orbit $\{\psi + \gamma t \mid 0 \leqslant t \leqslant T_n\}$ intersects S. If an orbit intersects S in an interior point (i.e., a point $\psi \in S \setminus \bigcup_{p=0}^{k-2} S_p$), then ψ is the unique point of intersection between the orbit and S. On the other hand, if an orbit intersects S in a noninterior point, then the orbit intersects S in other noninterior points as well. Observe that we have in $\mathbb{T}^k$ the flow defined by the rational frequency γ which permutes the various p faces whose union is S_p. We can then consider noninterior points of S as "boundary" points. Denote the set of such boundary points of S as ∂S.

In the detailed proof carried out in [44] the desired function A for which there is an E.D. for the corresponding system is obtained altering A_* many times to obtain a contradiction with Hypothesis 5.4. First a map from the boundary ∂S into the unit circle S^1 is defined, then, after proving that this map is homotopic to a constant for a suitable perturbation of A_*, this map is extended to the whole of S. Then, using Tietze's theorem, the map is extended to the space $\mathbb{T}^k$. In the end one obtains a continuous function defined on the entire space $\mathbb{T}^k$ and belonging to the open set V_2 for which the corresponding family of systems admits an E.D.

We include here the details for $k = 3$. In this case the quasi-section is the rectangle

$$S = \left\{ (\psi_1, \psi_2, \psi_3) \in \mathbb{T}^3 \,\middle|\, 0 \leqslant \psi_1 \leqslant \frac{2\pi}{q_1}, 0 \leqslant \psi_2 \leqslant \frac{2\pi}{q_2}, \psi_3 = 0 \right\}$$

in the ψ_1–ψ_2 plane. We already noticed that we can consider $\psi^0 = (0, 0, 0)$ as the lower-left hand vertex of the rectangle S.

We choose $\gamma_n = \gamma$ and A_0 such that the system $x' = A_0(\psi^0 + \gamma t)x$ has an E.D. and we can also assume (by choosing $\gamma = \gamma_n$ even closer to γ_*) that, for each $\psi \in S$, the resolvent interval $I_m(\psi)$ (if such an interval exists) corresponding to the (constant) value $\frac{2\pi m}{T_n}$ of the rotation number has length so small that, if $E : \mathbb{T}^k \to \mathbb{R}$ is a continuous function with $E(\psi) \in I_m(\psi)$ for any $\psi \in \mathbb{T}^k$, then the function $A_0 + JE$ belongs to V_2.

Let ψ^1, ψ^2, ψ^3 be the other vertices of the rectangle S in the $\psi_1 - \psi_2$ plane, where $\psi^1 = (0, \frac{2\pi}{q_2}, 0)$, $\psi^2 = (\frac{2\pi}{q_1}, 0, 0)$. We have then that $S = S_0 \cup S_1 \cup S_2$ where $S_0 = \{\psi^0, \psi^1, \psi^2, \psi^3\}$; $S_1 = \overline{\psi^0\psi^1} \cup \overline{\psi^1\psi^3} \cup \overline{\psi^2\psi^3} \cup \overline{\psi^0\psi^2}$ and S_2 is the interior of the rectangle which has vertices $\{\psi^0, \psi^1, \psi^2, \psi^3\}$. Observe that, when we consider the flow on $\mathbb{T}^3$ generated by the rational frequency γ, the segment $\overline{\psi^0\psi^1}$ is mapped to $\overline{\psi^2\psi^3}$ and the segment $\overline{\psi^0\psi^2}$ to the segment $\overline{\psi^1\psi^3}$. Let $t_1, t_2 \in [0, T_n)$ be the unique times such that $\tau_{t_i}(\psi^0) = \psi^0 + \gamma t_i = \psi^i$ $(i = 1, 2)$. We have then that $\psi^1 = \tau_{t_1}(\psi^0)$, $\psi^2 = \tau_{t_2}(\psi^0)$, and the other vertex $\psi^3 = \tau_{t_1+t_2}(\psi^0)$.

Before defining the desired function A (which will contradict Hypothesis 5.4), we make a digression to introduce the technique we will use. Let C_T be the set of T-periodic, continuous functions $\mathcal{A} : \mathbb{R} \to \mathrm{sl}(2, \mathbb{R})$. If $\mathcal{A} \in C_T$, consider the system

$$x' = \big[\mathcal{A}(t) + JE\big]x \tag{5.7}$$

where $E \in \mathbb{R}$ and $J = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Write $\mathcal{A} = \begin{pmatrix} a & -b+c \\ b+c & -a \end{pmatrix}$ and after considering the polar angle $\theta = \operatorname{Arg} x$, we have that θ verifies the equation

$$\theta' = \big(E + b(t)\big) - a(t)\sin 2\theta + c(t)\cos 2\theta. \tag{5.8}$$

If $\phi \in \mathbb{R}$, let $v_\phi = \begin{pmatrix} \cos\phi \\ \sin\phi \end{pmatrix}$. If $x(t)$ is the solution of Eq. (5.7) with the initial condition $x(0) = v_\phi$, then the solution $\theta(t)$ of Eq. (5.8) such that $\theta(0) = \phi$ is a continuous determination of $\arg x(t)$. Let m a fixed integer. It can be shown that there is a unique $E_m \in \mathbb{R}$ such that the solution $\theta(t, E_m)$ of Eq. (5.8) with $E = E_m$ and verifying the initial condition $\theta(0, E_m) = \phi$ satisfies

$$\theta(T, E_m) - \phi = 2\pi m.$$

Consider now the corresponding periodic operator $L = L_m = J^{-1}[\frac{\mathrm{d}}{\mathrm{d}t} - \mathcal{A}(t)]$ acting on $L^2(\mathbb{R}, \mathbb{C}^2)$. According to the discussion carried out on page 253, one has just two possibilities: either E_m is an element of the closure of a resolvent interval I_m of L, in which case the rotation number of the operator equals $\frac{2\pi m}{T}$ (parabolic case), or E_m defines a closed gap (elliptic case).

Define now $F^{\phi}(\mathcal{A}) = \mathcal{A} + JE_m$. Then F^{ϕ} is a nonlinear transformation from C_T into C_T which is continuous in the topology of the uniform convergence on $[0, T]$. Observe that, for each $\tilde{A} \in C_T$, v_{ϕ} is an eigenvector of the period matrix of the system $x' = F^{\phi}(\mathcal{A})(t)x$ (which is by definition $x' = [\mathcal{A}(t) + JE_m]x$). Moreover, if the rotation number of the system $x' = \mathcal{A}(t)x$ is already equal to $\frac{2\pi m}{T}$, then the transformation $F^{\phi}(\mathcal{A})$ is obtained from $\mathcal{A}$ by adding a translate JE_m such that $E_m = 0$ if the real number 0 defines a closed gap of L, and $|E_m|$ is no greater than the length of I_m if 0 is in the resolvent interval I_m of L.

We have finally that, for each $\phi \in \mathbb{R}$, the family (depending on the real parameter s) $F_s^{\phi} : C_T \to C_T$ defined by

$$F_s^{\phi}(\mathcal{A}) = \mathcal{A} + sJE_m \quad (0 \leqslant s \leqslant 1) \tag{5.9}$$

is an homotopy joining F^{ϕ} to the identity transformation on C_T. We will obtain the desired A – for which we will have an E.D. – using the functional F^{ϕ}.

Let r be a real parameter varying in the interval $[0, t_1 + t_2] = [0, t_1] \cup [t_1, t_1 + t_2]$. Let P_r be the projection defined by the presence of an E.D. for the translated equation $x' = A_0(\psi^0 + \gamma(t + r))x$ for $r \in [0, t_1 + t_2]$ for the translation invariance of the E.D. property. Extend the parameter r by letting it decrease from $t_1 + t_2$ to t_2, then from t_2 to 0. Consider a parametrization of the boundary ∂S of the section S given by the following map $\psi = \psi(r)$ with $0 \leqslant r \leqslant t_1 + t_2$.

$$\partial S := \begin{cases} \psi\colon\ [0, t_1] \to [\psi^0, \psi^1] \text{ is linear with } \psi(0) = \psi^0 \text{ and } \psi(t_1) = \psi^1, \\ \psi : [t_1, t_1 + t_2] \to [\psi^1, \psi^3] \text{ is linear with } \psi(t_1) = \psi^1 \\ \quad \text{and } \psi(t_1 + t_2) = \psi^3, \\ \psi : [t_1 + t_2, t_2] \to [\psi^3, \psi^2] \text{ is linear with } \psi(t_1 + t_2) = \psi^3, \\ \quad \psi(t_2) = \psi^2, \\ \psi : [t_2, 0] \to [\psi^2, \psi^0] \text{ is linear with } \psi(t_2) = \psi^2 \text{ and } \psi(0) = \psi^0. \end{cases}$$

Of course we have put $[\psi^0, \psi^1] = \overline{\psi^0\psi^1}, \ldots, [\psi^0, \psi^2] = \overline{\psi^0\psi^2}$ for the segments whose union is the boundary ∂S.

Now, we associate to each value of the parameter r a continuously determined argument $\theta(r)$ of the line in the plane $\mathbb{R}^2$ which is equal to the image of the projection P_r given by the presence of an E.D. Recall that when there is an E.D. the corresponding projection P has a one-dimensional range and a one dimensional kernel which are lines in the plane $\mathbb{R}^2$. For each $\psi \in \partial S$, let $v(\psi)$ be the unit vector in the plane $\mathbb{R}^2$ with polar angle $\theta(r)$ where r corresponds to the point ψ on the boundary ∂S. We have then that the map $v : \partial S \to S^1 : \psi \to v(\psi)$ is homotopic to a constant map. Here we indicate with S^1 the unit circle on the plane.

We define $A_1(\psi) = A_0(\psi) + JE(\psi)$ for $\psi \in \partial S$ as follows: if $\psi \in [\psi^0, \psi^1] \cup [\psi^1, \psi^3]$, let $A'_{\psi}(t) = A_0(\psi + \gamma t)$. Then let $A_{\psi}^{(1)}(t) = F^{\theta(r)}(A'_{\psi})(t)$ where r is the parameter which corresponds to the point ψ and $0 \leqslant t \leqslant T_n$. Finally set $A_1(\psi + \gamma t) = A_{\psi}^{(1)}(t)$ for $0 \leqslant t \leqslant$

T_n. We observe that A_1 is defined on a subset of the torus $\mathbb{T}^3$ containing the whole boundary ∂S. We also have that, if $\psi \in [\psi^0, \psi^1] \cup [\psi^1, \psi^3]$, then the solution $x_\psi(t) := x(t)$ of the corresponding (periodic) system $x' = A_\psi^{(1)}(t)x$ with initial condition $x_\psi(0) = v(\psi)$ has the property that $x(T_n)$ is a positive constant multiple of $v(\psi)$.

Next define $v_1(\psi) = v(\psi)$ if $\psi \in [\psi^0, \psi^1] \cup [\psi^1, \psi^3]$. If we consider $\psi \in [\psi^2, \psi^3]$, it follows that, by the properties of the flow generated on $\mathbb{T}^3$ by the rational frequency γ, there exists a unique $\tilde{\psi} \in [\psi^0, \psi^1]$ such that $\psi = \tilde{\psi} + \gamma t_2$. Define $v_1(\psi) = \frac{x_{\tilde{\psi}}(t_2)}{|x_{\tilde{\psi}}(t_2)|}$. Observe that the map $v_1(\psi)$ has values in the unit circle S^1. Moreover, if $\psi \in [\psi^0, \psi^2]$, there exists a unique $\tilde{\psi} \in [\psi^1, \psi^3]$ such that $\psi = \tilde{\psi} - \gamma t_1$ and, as before, we put $v_1(\psi) = \frac{x_{\tilde{\psi}}(-t_1)}{|x_{\tilde{\psi}}(-t_1)|}$. We have thus that the map v_1 is defined on the whole boundary ∂S with values in the unit circle S^1.

Consider now the map $f : \partial S \to C_T$ defined by $f(\psi)(t) = A_0(\psi + \gamma(t + r))$ where r is the parameter value corresponding to the point ψ on the boundary ∂S. Moreover we consider $g : \partial S \to C_T$ defined by $g(\psi)(t) = A_1(\psi + \gamma t)$. Using the contractibility of the space C_T, we have then that the maps f and g are homotopic via a homotopy $H : [0, 1] \times \partial S \to C_T : (s, \psi) \to H(s, \psi)$. This homotopy can be modified in a convenient way. First, using the transformation F^θ where $\phi = \theta$, we can arrange the homotopy in such a way that, for each $0 \leqslant s \leqslant 1$ and each $\psi \in [\psi^0, \psi^1] \cup [\psi^1, \psi^3]$, the corresponding system of equations $x' = H(s, \psi)(t)x$ has a solution $x_\psi(t)$ with $x_\psi(0) = v(\psi)$ and $x_\psi(T_n) = cv(\psi)$ where c is a positive number. Second, we can also impose some translation invariance relations.

(i) If $\psi \in [\psi^2, \psi^3]$ and $\tilde{\psi} \in [\psi^0, \psi^1]$ is the unique point such that $\psi = \tilde{\psi} + \gamma t_2$, then

$$H(s, \psi)(t) = H(s, \tilde{\psi})(t + t_2).$$

(ii) If $\psi \in [\psi^0, \psi^2]$ and if $\tilde{\psi} \in [\psi^1, \psi^3]$ is the unique point such that $\psi = \tilde{\psi} - \gamma t_1$, we arrange that

$$H(s, \psi)(t) = H(s, \tilde{\psi})(t - t_1).$$

Now, using the translation relations one can show that v and v_1 are homotopic as maps from the boundary ∂S to the unit circle S^1. We have hence that v_1 is homotopic to a constant map too and admits a continuous extension to all of S. Indicate with $v_1 : S \to S^1$ such an extension. When $\psi \in \operatorname{int} S$, let θ_ψ be a continuous determination of the polar angle of the unit vector $v_1(\psi)$. We now extend, using Tietze's theorem, the function A_1 to a continuous map (again called A_1) defined on all the torus. Then we redefine $A_1(\psi + \gamma t)$ to be $F^{\theta(\psi)}(A_\psi^{(1)})(t)$ $(\psi \in S,\ 0 \leqslant t \leqslant T_n)$. One can arrange that $A_1 \in V_2$. For each $\psi \in S$ (and hence for each ψ in the torus) one has a unit vector $v_1(\psi) \in \mathbb{R}^2$ varying continuously with ψ such that, if $x_\psi(t)$ is the solution of the system $x' = A_1(\psi + \gamma t)x$ with $x_\psi(0) = v_1(\psi)$, then $x_\psi(T_n) = cv_1(\psi)$ where $c > 0$. Now, if $c > 1$ for all $\psi \in \mathbb{T}^3$, then the corresponding system of equations has an E.D. over $\mathbb{T}^3$.

The last thing to do is alter the function A_1 for the last time, using a triangularization technique [50], to arrange that the corresponding Lyapunov exponent $\beta(\psi) > 0$ for all

$\psi \in \mathbb{T}^3$. Equivalently, $c > 1$ for all $\psi \in \mathbb{T}^3$. Now, putting everything together, we have arrived at a contradiction with Hypothesis 5.4 and then Theorem 5.1 is finally proved.

For $k > 3$, an analogous construction can be carried out. One constructs A starting from A_0 in an inductive way, modifying A_0 first on S_0, then on $S_1, S_2, \ldots, S_{k-1}$. There is no essential difficulty in passing from S_p to S_{p+1} for $p \geqslant 2$, for the following reason. Suppose that A has been defined on S_p. One wishes to define A along one of the $p+1$-faces $\mathcal{F}$ making up S_{p+1}. The boundary $\partial\mathcal{F}$ of $\mathcal{F}$ is a topological p-sphere which is a union of p-faces. When one carries out the appropriate analogue of the construction outlined above, one arrives at a crucial step in which one must extend a continuous map $v_1 : \partial\mathcal{F} \to S^1$ to a continuous map (again called v_1) from $\mathcal{F}$ to S^1. If $p \geqslant 2$ this is always possible because v_1 is homotopic to a constant map; see, e.g. Dugundji [37].

As one can see from the arguments given above, it seems quite difficult to obtain the same result considering the Hölder space $C^r(\mathbb{T}^k)$ with $r \geqslant 1$ instead of C_0. In view of the results obtained and the techniques used in the paper [45], we conjecture that Theorem 5.1 can be generalized to the case of $0 < r < 1$ but not to the case $r \geqslant 1$. We have already stated the first result on page 255 (Theorem 5.5), the second is the following [45]:

THEOREM 5.7. *Let $C^r = C^r(\mathbb{T}^k, \mathrm{sl}(2,\mathbb{R}))$ There is a dense subset $P_r \subset W_r = \Gamma \times C^r$ with the following property: if $w = (\gamma, A) \in P_r$, then the Lyapunov exponent $\beta = \beta(w)$ of the corresponding family of equations $x' = A(\psi + \gamma t)x$ is strictly positive.*

Both of these results hold for $0 \leqslant r < 1$, and this, together with the nature of their proofs, leads one to suspect that Theorem 5.1 also holds when $0 \leqslant r < 1$.

Observe that, using the Baire category theorem, we can give a "fixed-frequency" version of Theorem 5.1:

COROLLARY 5.8. *There is a residual subset $\Gamma_* \subset \Gamma$ such that, if $\gamma \in \Gamma_*$, then the set $\mathcal{D}_\gamma = \{A \in C_0 \mid x' = A(\psi + \gamma t)x$ has an E.D. over $\mathbb{T}^k\}$ is open and dense in C_0.*

Note first that the set Γ is a Baire space and thus it admits a metric with respect to which it is a complete metric space.

PROOF. The openness of the set $\mathcal{D}_\gamma$ in C_0 follows from Theorem 5.3 for all $\gamma \in \mathbb{R}^k$. It remains to prove the density result. Take a countable dense subset of C_0 given by $\{A_n \mid n = 1, 2, \ldots\}$ and indicate with $B_{j,n}$ the open ball in C_0 centered in A_n with radius $1/j$ where $j = 1, 2, \ldots$. Let $\Gamma_{n,j} = \{\gamma \in \Gamma \mid \text{for each} A \in B_{n,j}$ the system $x' = A(\psi + \gamma t)$ does not have an E.D. over $\mathbb{T}^k\}$. For Theorem 5.3, it follows that each $\Gamma_{n,j}$ is closed in Γ. Moreover Theorem 5.1 implies that each $\Gamma_{n,j}$ has no interior in Γ. If we put $\Gamma_* = \Gamma \setminus \bigcup\{\Gamma_{n,j} \mid n, j \geqslant 1\}$ we have that Γ_* is residual in Γ and it verifies the condition of corollary. □

Preface

This presentation is mainly devoted to considering growth and value distribution of meromorphic solutions of complex differential equations, both in the complex plane as well as in the unit disc. Our main emphasis is in results and considerations not to be found in the key references of the present field, namely [98] and [107] below. Therefore, results achieved during the last fifteen years or so play a special role, hence in particular recent investigations concerning linear differential equations in the unit disc. Conjectures and open problems as well as comments about defectively understood specific areas have been scattered in the text, hopefully prompting additional interest.

The book reference list [63,74,77,99,141] and [189] includes items known to us that cover, at least partially, our present point of view. Of course, these references include a lot of material not to be found in this presentation, due to lack of space. Additional book references of more specialized type can be found in the reference lists of specific chapters below.

After a short introduction into the local theory of complex differential equations, we first collect essentials about growth and value distribution of solutions of linear differential equations in the complex plane, followed by a survey of the very recent investigations about solutions of linear differential equations in the unit disc. The next chapter, non-linear differential equations in a complex domain, takes about one third of the whole presentation, including Malmquist type theorems, Riccati, Schwarzian, Painlevé and Briot–Bouquet differential equations, algebraic differential equations in general and their connections to differential fields. The final chapter offers a short presentation of algebroid solutions of complex differential equations, a field that definitely needs more studies.

1. Local theory of complex differential equations

In this section, we recall basic results of the local theory of complex differential equations. These results serve as a device to the existence of local solutions to a given differential equation in the complex plane, usually under given initial condition(s). In addition to the local existence, the global existence of solutions in a domain $G \subset \mathbf{C}$ may often be deduced. The solutions to be looked for are typically analytic or meromorphic or some slight extensions of these such as algebroid functions. For the convenience of the reader, we have included some proofs, not immediately available, in this section.

1.1. *Elementary background from several complex variables*

Let $\Omega \subset \mathbb{C}^n$ be an open set, equipped with the topology obtained from the standard Euclidean topology by identifying $\mathbb{C}^n$ with $\mathbb{R}^{2n}$. For a point $(z_1, \dots, z_n) \in \Omega$, let $x_1, \dots, x_{2n}$ denote its corresponding real coordinates, with the proviso that $z_j = x_{2j-1} + ix_{2j}$ for $j = 1, \dots, n$. Consider now a function $f : \Omega \to \mathbb{C}$ continuously differentiable with respect to $x_1, \dots, x_{2n}$. Defining the complex partial derivatives by

$$\frac{\partial f}{\partial z_j} := \frac{1}{2}\left(\frac{\partial f}{\partial x_{2j-1}} - \mathrm{i}\frac{\partial f}{\partial x_{2j}}\right), \tag{1.1.1}$$

$$\frac{\partial f}{\partial \bar{z}_j} := \frac{1}{2}\left(\frac{\partial f}{\partial x_{2j-1}} + \mathrm{i}\frac{\partial f}{\partial x_{2j}}\right), \tag{1.1.2}$$

the total differential

$$\mathrm{d}f := \sum_{j=1}^{2n} \frac{\partial f}{\partial x_j}\,\mathrm{d}x_j \tag{1.1.3}$$

may be written in the form

$$\mathrm{d}f = \partial f + \bar{\partial} f := \sum_{j=1}^{n} \frac{\partial f}{\partial z_j}\,\mathrm{d}z_j + \sum_{j=1}^{n} \frac{\partial f}{\partial \bar{z}_j}\,\mathrm{d}\bar{z}_j. \tag{1.1.4}$$

Recall now

DEFINITION 1.1.1. A continuously differentiable function $f : \Omega \to \mathbb{C}$ is *analytic* (*holomorphic*) in Ω, if $\bar{\partial} f = 0$ in Ω.

REMARK. If $n = 1$ and we denote $f = u + \mathrm{i}v$, $z = x + \mathrm{i}y$, Definition 1.1.1 reduces to the familiar Cauchy–Riemann equations in the classical sense.

In the local theory, the following several variables counterpart to the classical Taylor expansion is frequently needed. Using the notion of a *polydisc*

$$B(\beta, r) := \prod_{j=1}^{n} B(\beta_j, r_j), \tag{1.1.5}$$

where $\beta_j \in \mathbb{C}$, $r_j > 0$ for $j = 1, \ldots, n$ and $B(\beta_j, r_j) \subset \mathbb{C}$ is the open disc of radius r_j, centered at β_j, we prove the following theorem, see [85], p. 27:

THEOREM 1.1.2. *Suppose* $f : B(\beta, r) \to \mathbb{C}$ *is analytic. Then* f *may be uniquely represented as an absolutely converging power series*

$$f(z_1, \ldots, z_n) = \sum_{k_1,\ldots,k_n=0}^{\infty} a_{k_1,\ldots,k_n}(z_1 - \beta_1)^{k_1} \cdots (z_n - \beta_n)^{k_n}, \tag{1.1.6}$$

converging uniformly in compact subsets of $B(\beta, r)$. *If* $|f(z_1, \ldots, z_n)| \leqslant M$ *in* $\prod_{j=1}^{n} B(\beta_j, \rho_j)$, *where* $0 < \rho_j < r_j$, $j = 1, \ldots, n$, *then*

$$|a_{k_1,\ldots,k_n}| \leqslant \frac{M}{r_1^{k_1} \cdots r_n^{k_n}}. \tag{1.1.7}$$

By Theorem 1.1.2, it is not too difficult to prove the following theorem (due to Hartogs), which is of frequent (implicit) use in practical considerations of complex differential equations. For the proof of this theorem, see [85], pp. 28–29.

THEOREM 1.1.3. *If $f:\Omega\to\mathbb{C}$ is analytic in each of the complex variables $z_1,\dots,z_n$ separately, when all other variables are given arbitrary fixed values, then f is analytic in the sense of Definition* 1.1.1.

1.2. *Basic local existence and uniqueness results*

The classical existence result for solutions of first order differential equations reads as follows:

THEOREM 1.2.1. *Suppose $f:\Omega\to\mathbb{C}$ in a domain $\Omega\subset\mathbb{C}^2$ is analytic and $(z_0,w_0)\in\Omega$. Then there exists $R>0$ such that the initial value problem*

$$w'(z)=f\bigl(z,w(z)\bigr),\quad w(z_0)=w_0, \tag{1.2.1}$$

admits a unique analytic solution $w(z)$ in $B(z_0,R)$ such that $(z,w(z))\in\Omega$ for all $z\in B(z_0,R)$.

There are several classical ways to prove this theorem. We recall here three of the most standard of these proofs: (1) the method of successive approximations, (2) the Banach fixed point method and (3) the Cauchy majorant method. See [74,77] for more details.

The previous theorem may easily be extended to the corresponding existence and uniqueness result for solutions of systems of first order differential equations:

THEOREM 1.2.2. *Suppose that $f_j:\Omega\to\mathbb{C}$, $j=1,\dots,n$, are analytic in a domain $\Omega\subset\mathbb{C}^{n+1}$ and that $(z_0,w_{1,0},\dots,w_{n,0})\in\Omega$. Suppose also that for some $r>0$,*

$$\overline{B}(z_0,w_{1,0},\dots,w_{n,0};r):=\overline{B}(z_0,r)\times\prod_{j=1}^{n}\overline{B}(w_{j,0},r)\subset\Omega \tag{1.2.2}$$

and that $|f_j(z,w_1,\dots,w_n)|\leqslant M$, $j=1,\dots,n$, for all $(z,w_1,\dots,w_n)\in\overline{B}(z_0,w_{1,0},\dots,w_{n,0};r)$. Then the initial value problem

$$w_j'(z)=f_j\bigl(z,w_1(z),\dots,w_n(z)\bigr),\quad w_j(z_0)=w_{j,0},\quad j=1,\dots,n, \tag{1.2.3}$$

admits a unique analytic solution $(w_1(z),\dots,w_n(z))$ in some neighborhood U of z_0 such that

$$B\left(z_0,r\left(1-\exp\left(-\frac{1}{(n+1)M}\right)\right)\right)\subset U. \tag{1.2.4}$$

REMARK. The previous theorem has been formulated for a proof by the Cauchy majorant method. An interested reader may find a complete proof in [74], pp. 19–22.

A slight modification of the majorant method may be applied to prove that local solutions of a system of linear differential equations remain analytic as long as all coefficients are analytic, see [74], pp. 23–25:

THEOREM 1.2.3. *Let* $b_{jk}(z)$, $a_j(z)$, $j, k = 1, \dots, n$, *be analytic functions in* $B(z_0, r)$. *Then the initial value problem*

$$\begin{cases} w_j' = \displaystyle\sum_{k=1}^{n} b_{jk}(z) w_k + a_j(z), \quad j = 1, \dots, n, \\ w_1(z_0) = w_{1,0}, \dots, w_n(z_0) = w_{n,0} \end{cases} \tag{1.2.5}$$

possesses a unique solution $(w_1(z), \dots, w_n(z))$ *analytic in* $B(z_0, r)$.

Theorem 1.2.3 has two immediate corollaries of frequent use in practical considerations. To formulate these consequences, let $p_1(z), \dots, p_n(z), a(z)$ be analytic in $B(z_0, r)$ and consider the initial value problem

$$\begin{cases} w^{(n)} + p_1(z) w^{(n-1)} + \cdots + p_n(z) w = a(z), \\ w(z_0) = w_{0,0}, w'(z_0) = w_{1,0}, \dots, w^{(n-1)}(z_0) = w_{n-1,0}. \end{cases} \tag{1.2.6}$$

Clearly, Eq. (1.2.6) may be represented as the system of linear differential equations,

$$\begin{cases} w_j' = w_{j+1}, \quad j = 1, \dots, n-1, \\ w_n' = -p_n(z) w_1 - \cdots - p_1(z) w_n + a(z). \end{cases} \tag{1.2.7}$$

Therefore, an immediate consequence of Theorem 1.2.3 is

COROLLARY 1.2.4. *The initial value problem* (1.2.6) *possesses a unique solution* $w(z)$ *analytic in* $B(z_0, r)$.

In particular, this implies the following important global consequence:

COROLLARY 1.2.5. *If the coefficients of a linear differential equation* (1.2.6) *are entire functions, then all solutions of* (1.2.6) *are entire functions as well.*

In the case of non-linear differential equations, the conclusion corresponding to Corollary 1.2.4, i.e. proving that all local solutions remain meromorphic as long as the coefficients are analytic, is a complicated problem in general. Standard cases where global existence of meromorphic solutions can be proved, are the Riccati differential equation and the Painlevé differential equations. Concerning the Riccati differential equation, we get

THEOREM 1.2.6. *Suppose that the coefficients* a_0, a_1, a_2 *of the Riccati differential equation*

$$w' = a_0(z) + a_1(z)w + a_2(z)w^2 \tag{1.2.8}$$

are analytic in $B(z_0, r)$. *Then all local solutions of* (1.2.8) *in a simply connected domain* $\Omega \subset B(z_0, r)$ *admit a meromorphic continuation into* $B(z_0, r)$.

The basic idea to prove this theorem is to fix three distinct complex numbers c_1, c_2, c_3, and consider the following pair of differential equations:

$$\begin{cases} u' = a_0(z)v + a_1(z)u, \\ v' = -a_2(z)u. \end{cases} \tag{1.2.9}$$

By Theorem 1.2.3, (1.2.9) possesses a unique solution (u_j, v_j), $j = 1, 2, 3$, analytic in $B(z_0, r)$ and satisfying the initial conditions

$$u_j(z_0) = c_j, \quad v_j(z_0) = 1, \quad j = 1, 2, 3. \tag{1.2.10}$$

By elementary computation, $w_j = u_j/v_j$, $j = 1, 2, 3$, are three distinct solutions of (1.2.8), meromorphic in $B(z_0, r)$. To complete the proof, it suffices to recall that an arbitrary local solution w of a Riccati differential equation may be represented in terms of these three solutions, or actually in terms of their restrictions to the domain to be considered, see [9], Proposition 2.1. By the standard uniqueness theorem of meromorphic functions, w possesses the required meromorphic continuation.

COROLLARY 1.2.7. *Suppose the coefficients of the Riccati differential equation* (1.2.8) *are entire functions. Then all local solutions of* (1.2.8) *admit a meromorphic continuation into* $\mathbb{C}$.

Concerning the Painlevé differential equations, see Section 4.5.

Cauchy majorant method may easily be applied to prove the classical fact that local solutions depend analytically on initial values and parameters. For simplicity, we restrict ourselves to formulate the result for one parameter only. However, it is no difficulty indeed to permit several (finitely many) parameters in the assertion.

THEOREM 1.2.8. *Consider a parameter-depending initial value problem*

$$w' = f(z, w, \lambda), \quad w(z_0, \lambda_0) = w_0, \tag{1.2.11}$$

where f *is analytic in a domain* $\Omega \subset \mathbb{C}^3$, *containing the point* (z_0, w_0, λ_0). *Then* (1.2.11) *admits a unique analytic solution* $w(z, \lambda)$ *in a domain* $\Delta \subset \mathbb{C}^2$ *such that* $(z, w(z), \lambda) \in \Omega$ *for all* $(z, \lambda) \in \Delta$. *In particular, the dependence on the parameter* λ *is analytic in a neighborhood of* λ_0.

For the proof, see [74], pp. 26–27.

1.3. *Some remarks on the behavior of local solutions*

This section is devoted to considering some complements for the preceding basic existence and uniqueness results. We also consider analytic continuation of local solutions along curves on the complex plane and, secondly, possibilities of obtaining some information of solutions around such points in $\mathbb{C}^2$, where $f(z, w)$ has a singularity. Concerning the proofs in this section, see [22].

THEOREM 1.3.1. *Suppose* $f : \Omega \to \mathbb{C}$ *is analytic in a domain* $\Omega \subset \mathbb{C}^2$ *and* $(z_0, w_0) \in \Omega$. *Let further* U *be a neighborhood of* z_0. *Then the differential equation*

$$w' = f(z, w) \tag{1.3.1}$$

cannot possess a solution $w : U \setminus \{z_0\} \to \mathbb{C}$ *such that* w *would be analytic in* $U \setminus \{z_0\}$ *with an essential singularity at* z_0.

PROOF. Fix first $\overline{B}(z_0, w_0; r) \subset \Omega$ such that $\overline{B}(z_0, r) \subset U$, and assume that $|f(z, w)| \leqslant M$ in $\overline{B}(z_0, w_0; r)$. Assume then, contrary to the assertion, that w is analytic in $U \setminus \{z_0\}$, with an essential singularity at z_0. By the Casorati–Weierstraß theorem, we may construct a sequence $(z_j)_{j\in\mathbb{N}}$ of distinct points in $B(z_0, r)$ converging to z_0 such that $(w(z_j))_{j\in\mathbb{N}}$ is a sequence of distinct points in $B(w_0, r)$ converging to w_0. Moreover, we may assume that $z_j \neq z_0$, $w(z_j) = w_j \neq w_0$, and that $(z_j, w_j) \in \overline{B}(z_0, w_0; \frac{r}{2})$. By the local existence theorem, the initial value problem

$$w'(z) = f\bigl(z, w(z)\bigr), \quad w(z_j) = w_j \tag{1.3.2}$$

has a unique analytic solution in some neighborhood U_j of z_j such that $B(z_j, \frac{r}{2}(1 - \exp(-\frac{1}{2M})) \subset U_j$. Therefore, $w(z)$ equals with this local solution determined by the existence theorem. If $|z_j - z_0| < \frac{r}{2}(1 - \exp(-\frac{1}{2M}))$, we conclude that $w(z)$ must be analytic at z_0, a contradiction. □

Actually, the above theorem is a corollary of the following theorem, originally due to Painlevé:

THEOREM 1.3.2. *Suppose that* $f : \Omega \to \mathbb{C}$ *is analytic in a domain* $\Omega \subset \mathbb{C}^2$ *and that* $(z_0, w_0) \in \Omega$. *Let* $w(z; z_0, w_0)$ *be the unique analytic solution of the initial value problem*

$$w' = f(z, w), \quad w(z_0) = w_0. \tag{1.3.3}$$

Moreover, let $\gamma : [0, 1] \to \Omega$ *be a Jordan curve such that* $\gamma(0) = z_0$, $\gamma(1) = a \neq z_0$, *and assume that* $w(z; z_0, w_0)$ *permits an analytic continuation along the curve* γ *such that* $(\gamma(t), w(\gamma(t); z_0, w_0)) \in \Omega$ *for all* $t \in [0, 1)$. *Finally, suppose that for a sequence* $(z_j)_{j\in\mathbb{N}}$ *on the curve* γ *such that* $z_j \to a$, *we have* $\lim_{j\to\infty} w(z_j; z_0, w_0) = \alpha \in \mathbb{C}$ *with* $(a, \alpha) \in \Omega$. *Then* $w(z; z_0, w_0)$ *permits an analytic continuation along the curve* γ *over the end-point* a *and we have* $w(z; z_0, w_0) = w(z; a, \alpha)$ *locally in some neighborhood of* a.

PROOF. We now fix $r > 0$ such that $\overline{B}(a, \alpha; 2r) \subset \Omega$, assuming that $|f(z, w)| \leqslant M$ in $\overline{B}(a, \alpha; 2r)$. We also choose, as we may by our assumptions, $(\zeta, \omega) \in \Omega$ such that

$$\zeta \in \gamma,\ \zeta \neq a, \quad |\zeta - a| < R := r\left(1 - \exp\left(-\frac{1}{2M}\right)\right) \tag{1.3.4}$$

and that for $\omega := w(\zeta; z_0, w_0)$ we have $|\omega - \alpha| < r$. Clearly, we then have $w(z; z_0, w_0) = w(z; \zeta, \omega)$ in some neighborhood of ζ by the basic existence and uniqueness theorem and by our assumption on the analytic continuation of $w(z; z_0, w_0)$. Since $\overline{B}(\zeta, \omega; r) \subset \overline{B}(a, \alpha; 2r)$ by the triangle inequality, the local solution $w(z; \zeta, \omega)$ must be analytic at least in $B(\zeta, R)$. Since $w(z_j; z_0, w_0) \to \alpha$ as $j \to \infty$, we must have $w(a; \zeta, \omega) = \alpha$. By the uniqueness of local solutions, $w(z; a, \alpha) = w(z; \zeta, \omega)$, implying the second assertion. □

In order to continue our considerations on the analytic continuations of local solutions, we turn our attention to the poles of $f(z, w)$. We say that (z_0, w_0) is a *pole* of $f(z, w)$, provided that $1/f(z, w)$ is analytic in a neighborhood of (z_0, w_0) and that $1/f(z_0, w_0) = 0$. As an example, $f(z, w) := 1/(z + w)$ has a pole at every point $(z_0, -z_0)$, $z_0 \in \mathbb{C}$.

PROPOSITION 1.3.3. *Suppose that* $f(z, w)$ *has a pole at* $(z_0, w_0) \in \mathbb{C}^2$ *and that* $1/f(z_0, w)$ *does not vanish identically. Then the differential equation* $w' = f(z, w)$ *admits, locally around* z_0*, a multivalent solution* $\widetilde{w}(z)$ *such that* $\widetilde{w}(z_0) = w_0$.

PROOF. Consider the initial value problem

$$z'(w) = \frac{1}{f(z(w), w)}, \quad z(w_0) = z_0. \tag{1.3.5}$$

By Theorem 1.2.1, this initial value problem admits a unique analytic solution $z(w)$ locally around z_0. Since $1/f(z, w)$ does not vanish identically, $z(w)$ cannot be a constant. Moreover,

$$z'(w_0) = \frac{1}{f(z(w_0), w_0)} = \frac{1}{f(z_0, w_0)} = 0. \tag{1.3.6}$$

Therefore, the Taylor expansion of $z(w)$ around w_0 takes the form

$$z(w) = z_0 + c_k(w - w_0)^k + \cdots, \quad c_k \neq 0,\ k > 1. \tag{1.3.7}$$

Clearly, by (1.3.7), $z(w)$ admits, locally around z_0, a multivalent inverse function $w(z)$ satisfying the assertion. □

REMARK. The solution $\widetilde{w}$, $\widetilde{w}(z_0) = w_0$ constructed in Proposition 1.3.3 is unique in the following sense: If $\widetilde{w}(z) \to w_0$ as $z \to z_0$ along a Jordan curve γ, and if $z \in \gamma$ is sufficiently close to z_0, then $\widetilde{w}(z)$ must locally coincide around z with a branch of the multivalued solution of $w' = f(z, w)$ in Proposition 1.3.3. Indeed, since $\widetilde{w}'(z) = f(z, \widetilde{w}(z))$

along the curve γ, and (z_0, w_0) is a pole of $f(z, w)$, then $\widetilde{w}'(z) \neq 0$ for any $z \in \gamma$ sufficiently close to z_0. Therefore, $\widetilde{w}(z)$ admits an analytic local inverse around z, satisfying the differential equation in (1.3.5). Clearly, this inverse function may be continued along the curve γ, approaching to z_0. By Theorem 1.3.2, the inverse function must coincide with the $z(w)$ constructed in the proof of Proposition 1.3.3.

REMARK. Before proceeding, we introduce a couple of standard notations. In the case of Proposition 1.3.3, we say that the multi-valued function $w(z)$ has an *algebraic branch point* at z_0. Similarly, we say that z_0 is an *algebraic pole* of w at z_0, if w is multivalent around z_0, $t(z_0) := 1/w(z_0) = 0$, and if the local inverse $z(t)$ of $t(z) := 1/w(z)$ around 0 admits a local expansion of type

$$z(t) = z_0 + c_k t^k + \cdots, \quad c_k \neq 0,\ k > 1. \tag{1.3.8}$$

To complete this section, we consider the equation (1.3.1) in the special case where $f(z, w)$ is either a polynomial or a rational function in w.

THEOREM 1.3.4. *Considering*

$$w' = P(z, w) = \sum_{j=0}^{n} p_j(z) w^j, \quad n \geqslant 2, \tag{1.3.9}$$

assume that the coefficients $p_j(z)$ are analytic in a domain $\Omega \subset \mathbb{C}$. If $a \in \Omega$ and $p_n(a) \neq 0$, for $n > 2$, and if $w(z)$ is a solution of (1.3.9) *analytic on a Jordan curve $\gamma : [0, 1) \to \Omega$ from z_0 to a, then either* (i) *$w(z)$ permits a meromorphic continuation over a, or* (ii) *$w(z)$ has an algebraic pole at a.*

PROOF. Suppose first that $w(z)$ remains bounded on γ as $z \to a$. Then there is a sequence (z_j) on γ converging to a such that $w(z_j)$ converges to some $\alpha \neq \infty$ as $z_j \to a$. By Theorem 1.3.2, $w(z)$ permits an analytic continuation over a. Otherwise, we may find a sequence (z_j) on γ such that $w(z_j) \to \infty$ as $z_j \to a$. By the transformation $v := 1/w$ we obtain

$$v' = Q(z, v) = -\frac{1}{v^{n-2}}\big(p_0(z)v^n + \cdots + p_n(z)\big). \tag{1.3.10}$$

If now $n = 2$, then $Q(z, v)$ is analytic around $(a, 0)$. By the first part of the proof, $v(z)$ has an analytic continuation over a, hence w has a meromorphic continuation over a with a pole at a. Finally, if $n > 2$, then $Q(z, v)$ has a pole at $(a, 0)$ and $1/Q(a, v)$ does not vanish identically. By Proposition 1.3.3, the case (ii) follows. □

THEOREM 1.3.5. *Consider now*

$$w' = \frac{P(z, w)}{Q(z, w)}, \tag{1.3.11}$$

where $P(z,w)$, $Q(z,w)$ *are polynomials in* w *with analytic coefficients in a domain* $\Omega \subset \mathbb{C}$. *Assume that* $a \in \Omega$, *that* $\deg_w Q \geqslant 1$ *and that* $Q(a,w)$ *does not vanish identically. Moreover, we assume that* $P(a,w)$ *and* $Q(a,w)$ *have no common factors. If now* $w(z)$ *is a solution of* (1.3.11) *analytic on a Jordan curve* $\gamma : [0,1) \to \mathbb{C}$ *from* z_0 *to* a *in* Ω, *then either* (i) $w(z)$ *permits a meromorphic continuation over* a, *or* (ii) $w(z)$ *has an algebraic branch point at* a, *or* (iii) $w(z)$ *has an algebraic pole at* a.

PROOF. Since $Q(a,w)$ does not vanish identically, it has finitely many zeros as a polynomial of w, say $w_1,\dots,w_k$. By the non-existence of common factors, $P(a,w_j) \neq 0$ for all $j=1,\dots,k$. Given $\varepsilon > 0$, consider the set

$$H(\varepsilon) := \bigl\{ w \mid |w| \leqslant 1/\varepsilon, |w-w_j| \geqslant \varepsilon, j=1,\dots,k \bigr\}, \tag{1.3.12}$$

and fix ε_0 sufficiently small. Assume first that for every ε, $0<\varepsilon<\varepsilon_0$, there exists some $t_\varepsilon \in [0,1)$ such that $w(\gamma(t)) \in \mathbb{C} \setminus H(\varepsilon)$ for all $t \in [t_\varepsilon, 1)$. By continuity of w, we may conclude that only one of the inequalities

$$\bigl|w\bigl(\gamma(t)\bigr) - w_j\bigr| < \varepsilon, \quad j=1,\dots,k, \quad \bigl|w\bigl(\gamma(t)\bigr)\bigr| > 1/\varepsilon \tag{1.3.13}$$

holds for all $t \in [t_\varepsilon, 1)$, provided ε_0 is small enough. Therefore, we must have either $w(z) \to \infty$ or $w(z) \to w_j$ for some $j=1,\dots,k$ as $z \to a$ along the curve γ. If $w(z) \to w_j$, we have $Q(a,w_j)=0$, $P(a,w_j) \neq 0$, while $Q(a,w)$ does not vanish identically. Therefore, by Proposition 1.3.3, we have the case (ii) at hand. If then $w(z) \to \infty$, we substitute $w = 1/v$, resulting in

$$v' = -\frac{P_1(z,v)}{Q_1(z,v)} = v^2 \frac{P(z,1/v)}{Q(z,1/v)}, \tag{1.3.14}$$

and we have two subcases to consider. If $Q_1(a,0) \neq 0$, then $v(z)$ permits an analytic continuation over a, and $v(a) = 0$. Therefore, w has a pole at a, permitting a meromorphic continuation over a. If, on the other hand, $Q_1(a,0)=0$, then clearly $P_1(a,0) \neq 0$. Moreover, $Q_1(a,v)$ cannot vanish identically, since $Q(a,w)$ does not vanish identically. By Proposition 1.3.3 again, v has an algebraic branch point at a with $v(a)=0$. But this implies that w has an algebraic pole at a, and we have the case (iii).

It remains to consider the case that for some sequence (t_j) converging to 1 as $j \to \infty$, $w(\gamma(t_j)) \in H(\varepsilon)$. Since $H(\varepsilon)$ is a compact set, we may assume, by taking a subsequence, if needed, that $w(\gamma(t_j))$ converges to some point $w_0 \neq w_1,\dots,w_k,\infty$. Therefore, $P(z,w)/Q(z,w)$ is analytic at (a,w_0). By Theorem 1.3.2, w permits an analytic continuation over the point a. □

1.4. *Local behavior of solutions of* $w' = P(z,w)/Q(z,w)$

In this section, we consider the local behavior of solutions of the differential equation

$$w' = \frac{P(z,w)}{Q(z,w)}, \tag{1.4.1}$$

where $P(z,w)$, $Q(z,w)$ both are analytic in both variables. If the initial value $w(z_0)=w_0$ is to be satisfied, and if $Q(z_0,w_0)\neq 0$, resp. $Q(z_0,w_0)=0$ and $P(z_0,w_0)\neq 0$, we may apply Theorem 1.3.2, resp. Proposition 1.3.3, provided that $Q(z_0,w)/P(z_0,w)$ does not vanish identically. If then $P(z_0,w_0)=Q(z_0,w_0)=0$, the situation becomes more complicated. We may assume that $(z_0,w_0)=(0,0)$, hence we have to consider the differential equation (1.4.1) under the initial value $w(z_0)=w_0$ in the case of

$$\begin{aligned} P(z,w) &= \alpha z+\beta w+\sum_{j+k\geqslant 2} p_{jk}z^j w^k,\\ Q(z,w) &= \gamma z+\delta w+\sum_{j+k\geqslant 2} q_{jk}z^j w^k. \end{aligned} \tag{1.4.2}$$

The basic idea to handle this initial value problem is to normalize the equation by a suitable linear transformation. Indeed, it appears that the linear terms in (1.4.2) are essential for the behavior of solutions of (1.4.1) around $z=0$. In this section, we restrict ourselves to considering two special cases only, leaving aside more general considerations. Concerning the role of non-linear terms, it should perhaps be mentioned, however, that they may have a substantial influence in some cases. As an example, the non-vanishing solutions of

$$w'=\frac{-w+zw^2}{z} \tag{1.4.3}$$

may be expressed, locally around a point $z\neq 0$ close to the origin, in the form

$$w(z)=\frac{1}{z(C-\log z)},\quad C\in\mathbb{C}, \tag{1.4.4}$$

while for

$$w'=-\frac{w}{z} \tag{1.4.5}$$

we have the solutions

$$w(z)=\frac{C}{z},\quad C\in\mathbb{C}. \tag{1.4.6}$$

1.4.1. *The linear case* This section is devoted to considering the non-singular linear case

$$w'=\frac{\alpha w+\beta z}{\gamma w+\delta z},\quad \alpha,\beta,\gamma,\delta\in\mathbb{C},\ \alpha\delta-\beta\gamma\neq 0. \tag{1.4.7}$$

It appears that (1.4.7) is, essentially, equivalent to the following pair of linear differential equations:

$$\begin{cases} w'=\alpha w+\beta z,\\ z'=\gamma w+\delta z. \end{cases} \tag{1.4.8}$$

Indeed, let $w(z)$ be a meromorphic solution of (1.4.8), satisfying the initial condition $w(z_0) = w_0 \neq \infty$. Then, obviously, $\gamma w(z) + \delta z$ does not vanish identically. Fixing now $t_0 \in \mathbb{C}$ arbitrarily, we may solve, at least locally, $z(t)$ from the linear differential equation

$$\frac{\mathrm{d}z}{\mathrm{d}t} = \gamma w(z) + \delta z, \quad z(t_0) = z_0. \tag{1.4.9}$$

But then, considering $w = w(t) := w(z(t))$, we have

$$w(t_0) = w\big(z(t_0)\big) = w(z_0) = w_0 \tag{1.4.10}$$

and

$$\frac{\mathrm{d}w}{\mathrm{d}t} = \frac{\mathrm{d}w}{\mathrm{d}z}\frac{\mathrm{d}z}{\mathrm{d}t} = \frac{\alpha w(z) + \beta z}{\gamma w(z) + \delta z}\big(\gamma w(z) + \delta z\big) = \alpha w(z) + \beta z. \tag{1.4.11}$$

Conversely, let $(w(t), z(t))$ be a meromorphic solution of (1.4.9), satisfying the finite initial conditions $w(t_0) = w_0$, $z(t_0) = z_0$ for an arbitrarily given t_0. However, we have to assume that $(z_0, w_0) \neq (0, 0)$, since $z_0 = w_0 = 0$ would result in $w(t) \equiv 0$, $z(t) \equiv 0$ by Theorem 1.2.1. Since $\alpha\delta - \beta\gamma \neq 0$, we conclude from (1.4.9) that $|w'(t_0)|^2 + |z'(t_0)|^2 > 0$. Assuming that $z'(t_0) \neq 0$, we infer that the inverse function $t(z)$ is locally defined around z_0. But then

$$\widetilde{w}(z) := w\big(t(z)\big) \tag{1.4.12}$$

satisfies

$$\widetilde{w}(z_0) = w\big(t(z_0)\big) = w(t_0) = w_0 \tag{1.4.13}$$

and

$$\widetilde{w}'(z) = w'\big(t(z)\big) = \frac{\mathrm{d}w}{\mathrm{d}t}\frac{\mathrm{d}t}{\mathrm{d}z} = \frac{\alpha w + \beta}{\gamma w + \delta}. \tag{1.4.14}$$

Therefore, it means no essential restriction to consider the pair (1.4.8) of differential equations. Denoting

$$\Phi = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \tag{1.4.15}$$

we may represent (1.4.9) in vector notation as

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} w \\ z \end{pmatrix} = \Phi \begin{pmatrix} w \\ z \end{pmatrix}. \tag{1.4.16}$$

Let now Γ be a 2×2-matrix of complex numbers such that $\det \Gamma \neq 0$, to apply the linear transformation

$$\begin{pmatrix} w \\ z \end{pmatrix} = \Gamma \begin{pmatrix} \omega \\ \zeta \end{pmatrix} \tag{1.4.17}$$

to (1.4.16). This results in

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} \omega \\ \zeta \end{pmatrix} = \Gamma^{-1}\Phi\Gamma \begin{pmatrix} \omega \\ \zeta \end{pmatrix}. \tag{1.4.18}$$

By an elementary fact from linear algebra, we may choose Γ to satisfy

$$\Gamma^{-1}\Phi\Gamma = \begin{pmatrix} \lambda_1 & \mu \\ 0 & \lambda_2 \end{pmatrix}, \tag{1.4.19}$$

where $\mu = 0$, if $\lambda_1 \neq \lambda_2$. Therefore, two possibilities essentially cover the linear case:

(1) If $\lambda_1 = \lambda_2$, then (1.4.18) takes the form

$$\frac{\mathrm{d}\omega}{\mathrm{d}t} = \lambda_1\omega + \mu\zeta, \qquad \frac{\mathrm{d}\zeta}{\mathrm{d}t} = \lambda_1\zeta, \tag{1.4.20}$$

and so

$$\frac{\mathrm{d}\omega}{\mathrm{d}\zeta} = \frac{\omega + \alpha\zeta}{\zeta}, \quad \alpha \neq 0. \tag{1.4.21}$$

Now, any local solution of (1.4.21) at a point $\zeta \neq 0$ near the origin takes the form

$$\omega(\zeta) = \zeta(\alpha \log \zeta + C), \quad C \in \mathbb{C}, \tag{1.4.22}$$

where we may take the branch of the logarithm to satisfy $\log 1 = 0$. If now γ is a Jordan curve ending at $\zeta = 0$ with the representation $\zeta = \rho \exp(\mathrm{i}\varphi(\rho))$, then $\zeta \log \zeta = (\rho \cos \varphi + \mathrm{i} \sin \varphi)(\log \rho + i\varphi(\rho))$, from which we compute that

$$|\zeta \log \zeta|^2 = (\rho \log \rho)^2 + \bigl(\rho\varphi(\rho)\bigr)^2. \tag{1.4.23}$$

Combining now (1.4.22) and (1.4.23), we observe that $\lim_{\zeta\to 0} \omega(\zeta) = 0$ if and only if $\lim_{\rho\to 0} \rho\varphi(\rho) = 0$.

(2) If $\lambda_1 \neq \lambda_2$, then (1.4.18) reduces to

$$\frac{\mathrm{d}\omega}{\mathrm{d}t} = \lambda_1\omega, \qquad \frac{\mathrm{d}\zeta}{\mathrm{d}t} = \lambda_2\zeta, \tag{1.4.24}$$

hence

$$\frac{\mathrm{d}\omega}{\mathrm{d}\zeta} = \beta\frac{\omega}{\zeta}, \quad \beta \neq 0. \tag{1.4.25}$$

In this case, we get

$$\omega(\zeta) = C\zeta^{\beta} = C\mathrm{e}^{\beta \log \zeta}, \quad C \in \mathbb{C}. \tag{1.4.26}$$

Let again γ be a curve ending at $\zeta = 0$, represented by $\zeta = \rho \exp(\mathrm{i}\varphi(\rho))$. Denoting $\beta = \beta_1 + \mathrm{i}\beta_2$, where β_1, β_2 are real numbers, we obtain

$$\mathrm{e}^{\beta \log \zeta} = \mathrm{e}^{\beta \log(\rho \exp(\mathrm{i}\varphi))} = \mathrm{e}^{(\beta_1 + \mathrm{i}\beta_2)(\log \rho + \mathrm{i}\varphi(\rho))}, \tag{1.4.27}$$

and therefore

$$|\mathrm{e}^{\beta \log \zeta}| = \mathrm{e}^{\beta_1 \log \rho - \beta_2 \varphi(\zeta)}. \tag{1.4.28}$$

To consider the behavior of $\omega(\zeta)$ as $\zeta \to 0$, let us first assume that $\beta_2 = 0$. Then we have $\lim_{\zeta \to 0} \omega(\zeta) = 0$, if $\beta < 0$, and $\lim_{\zeta \to 0} \omega(\zeta) = \infty$, if $\beta > 0$. Supposing now that $\beta_2 \neq 0$, then we have $\lim_{\zeta \to 0} \omega(\zeta) = 0$, provided that $\beta_1 > 0$. On the other hand, if $\beta_1 \leqslant 0$, we then may always find a curve γ such that $\omega(\zeta)$ doesn't converge to 0 as $\zeta \to 0$ along γ.

1.4.2. *A non-linear case: a glimpse at the Briot–Bouquet theory* As an example of a non-linear case, we first consider

$$zw' = \lambda w + p_{10} z + \sum_{j,k=1}^{\infty} p_{jk} z^j w^k, \quad \lambda \in \mathbb{C} \tag{1.4.29}$$

with constant coefficients. This is the most simple case of what are usually called as Briot–Bouquet equations.

THEOREM 1.4.1. *If* $\lambda \in \mathbb{C} \setminus \mathbb{N}$, *then* (1.4.29) *admits a local analytic solution in a neighborhood of* $z = 0$. *The solution satisfying the initial condition* $w(0) = 0$ *is unique.*

PROOF. For a proof based on the Cauchy majorant method, see [74], pp. 55–56. □

This theorem is a special case of more general systems of differential equations having a singular point of regular type at $z = 0$. We may write such a system in the form

$$zy_j' = f_j(z, y_1, \ldots, y_n), \quad j = 1, \ldots, n, \tag{1.4.30}$$

where the right-hand sides $f_j(z, y_1, \ldots, y_n) = f_j(z, \mathbf{y})$ are analytic around $(z, \mathbf{y}) = (0, \mathbf{0})$, and assume that the initial conditions $f_j(0, \mathbf{0}) = 0$ are satisfied for $j = 1, \ldots, n$. Systems of this type are called Briot–Bouquet systems. Of course, we may write (1.4.30) in vectorial form as

$$zY' = F(z, Y), \tag{1.4.31}$$

where $Y = {}^t(\mathbf{y}) \in \mathbb{C}^n$ and $F(z,Y) = {}^t(f_1(z,Y),\dots,f_n(z,Y))$. Denoting $K := (k_1, \dots, k_n) \in (\mathbb{N} \cup \{0\})^n$, $|K| := k_1 + \cdots + k_n$, $A_{jK} := {}^t(a_{jK}^{(1)}, \dots, a_{jK}^{(n)}) \in \mathbb{C}^n$, $||Y|| := \max_j |y_j|$ and $Y^K := y_1^{k_1} \cdots y_n^{k_n}$, the power series expansion

$$F(z,Y) = \sum_{j+|K| \geqslant 1} A_{jK} z^j Y^K \tag{1.4.32}$$

converges in some domain around the origin, say $|z| < r_0$, $||Y|| < R_0$. Then we obtain the following

THEOREM 1.4.2. *If none of the eigenvalues of the matrix*

$$A = \begin{pmatrix} \frac{\partial f_1}{\partial y_1}(0,\mathbf{0}) & \cdots & \frac{\partial f_1}{\partial y_n}(0,\mathbf{0}) \\ \vdots & & \vdots \\ \frac{\partial f_n}{\partial y_1}(0,\mathbf{0}) & \cdots & \frac{\partial f_n}{\partial y_n}(0,\mathbf{0}) \end{pmatrix}$$

is a natural number, then Eq. (1.4.31) *admits a unique solution of the form*

$$Y(z) = \sum_{j=1}^{\infty} C_j z^j, \quad C_j \in \mathbb{C}^n, \tag{1.4.33}$$

analytic in a neighborhood of the origin.

PROOF. See [97], pp. 261–263. □

2. Linear differential equations in the complex plane

Despite of the extensive literature on linear differential equations in a real domain as well as in abstract spaces such as Banach spaces etc., the global theory of linear differential equations in the complex plane has a surprisingly short research history. Of course, global theory may be understood in a variety of different ways. In this connection, it will be meant to studying properties of solutions defined in the whole complex plane. Moreover, we assume that the solutions under consideration are meromorphic (or algebroid) in the plane. In this sense, the birth of Nevanlinna theory in 1920's was a decisive step towards such global investigations. Indeed, Nevanlinna theory has been the key method in this field since 1929 when F. Nevanlinna considered [136] the differential equation $f'' + A(z)f = 0$ in the case of a polynomial coefficient $A(z)$. A more continuous activity had to wait until 1950's, started by Wittich, see e.g. [189] and Frei [44]. In late 1960's and in 1970's, most of the research made in this field was due to S. Bank and former students of Wittich (J. Nikolaus, G. Frank, E. Mues). The papers [14,15] by S. Bank and the present author in 1982 prompted extensive activity in the field of linear differential equations, having been continued ever since. In this section, we concentrate ourselves to presenting recent developments in the field during the last fifteen years, as there are two relevant sources [98], [107] covering previous investigations. Also, the book [76] by E. Hille contains a lot of classical material about complex differential equations.

For the convenience of the reader, we recall here some of the key notations and basic results of the Nevanlinna theory, due to its importance to understand a lot of the material presented below.

Given a non-constant meromorphic function, denote by $n(r, f)$ the number of poles of f, resp. by $n(r, \frac{1}{f-a}) = n(r, a, f)$ the number of a-points of f in the disc $|z| \leqslant r$, each such point being counted according to its multiplicity. The respective *counting functions* are now obtained by logarithmic integration:

$$N\left(r, \frac{1}{f-a}\right) := \int_0^r \frac{n(t, a, f) - n(0, a, f)}{t}\,\mathrm{d}t + n(0, a, f)\log r,$$

resp.

$$N(r, f) := \int_0^r \frac{n(t, f) - n(0, f)}{t}\,\mathrm{d}t + n(0, f)\log r.$$

The corresponding *proximity functions* will be defined as the following integrals over the boundary $|z| = r$:

$$m\left(r, \frac{1}{f-a}\right) := \frac{1}{2\pi}\int_0^{2\pi} \log^+\left|\frac{1}{f(re^{\mathrm{i}\theta}) - a}\right| \mathrm{d}\theta$$

and

$$m(r, f) := \frac{1}{2\pi}\int_0^{2\pi} \log^+\left|f(re^{\mathrm{i}\theta})\right| \mathrm{d}\theta,$$

where $\log^+ a := \max(0, \log a)$ for $a \geqslant 0$. The *characteristic function* of f is nothing but the sum of the proximity function and the counting function:

$$T(r, f) := m(r, f) + N(r, f).$$

Using this notion, the *order* of f is defined as

$$\rho(f) := \limsup_{r\to\infty} \frac{\log T(r, f)}{\log r}.$$

Observe that this definition extends the classical order notion for entire functions, where $\log M(r, f)$ is used instead of $T(r, f)$; these two notions are not identical, but close enough to result in the same order value (in the complex plane, but not necessarily in the unit disc, say).

The celebrated *first main theorem* in Nevanlinna theory now tells an almost complete balance between the number of a-points and the affinity of f towards the value $a \in \mathbb{C}$:

THEOREM 2.0.3. *For a non-constant meromorphic function f and for an arbitrary complex value a,*

$$T\left(r, \frac{1}{f-a}\right) = T(r, f) + \mathrm{O}(1).$$

Here the bounded error term slightly depends on the value a.

The characteristic function may be used to separate rational functions from the non-rational ones: A meromorphic function f is rational if and only if $T(r, f) = \mathrm{O}(\log r)$.

Although the first main theorem is one of the great achievements in function theory during the last century, the really deep component in the Nevanlinna theory is the *lemma of the logarithmic derivative*:

THEOREM 2.0.4. *Let f be a non-constant meromorphic function, and k be any natural number. Then*

$$m\left(r, \frac{f^{(k)}}{f}\right) = S(r, f),$$

where $S(r, f) = \mathrm{o}(T(r, f))$ outside of a possible exceptional set of finite linear measure as $r \to \infty$. If f is of finite order, then

$$m\left(r, \frac{f^{(k)}}{f}\right) = \mathrm{O}(\log r)$$

without an exceptional set.

The logarithmic derivative lemma is the key device to prove the *second main theorem*, which is a far-reaching refinement of the great Picard theorem. We give here a simplified version only:

THEOREM 2.0.5. *Let f be a non-constant meromorphic function, let $q \geqslant 2$ and let $a_1, \dots, a_q$ be distinct complex numbers. Then*

$$m(r, f) + \sum_{j=1}^{q} m\left(r, \frac{1}{f-a_j}\right) \leqslant 2T(r, f) + S(r, f).$$

Defining now the *deficiency* for $a \in \widehat{\mathbb{C}}$ by

$$\delta(a, f) := \liminf_{r\to\infty} \frac{m(r, 1/(f-a))}{T(r, f)},$$

the second main theorem immediately implies the fact that $\delta(a, f) = 0$ except for at most countably many exceptional values, and that

$$\sum_{a \in \widehat{\mathbf{C}}} \delta(a, f) \leqslant 2.$$

In addition to the deficiency, a *ramification index* $\vartheta(a, f)$ will also be applied in what follows. This is used to obtain some information of multiple values of f. To this end, we just count a-points, resp. poles, of f in such a way that its multiplicity will be reduced by one, using notation $N_1(r, \frac{1}{f-a})$, resp. $N_1(r, f)$, for the corresponding integrated counting functions. We then define

$$\vartheta(a, f) := \liminf_{r \to \infty} \frac{N_1(r, 1/(f-a))}{T(r, f)}, \qquad \vartheta(\infty, f) := \liminf_{r \to \infty} \frac{N_1(r, f)}{T(r, f)}.$$

Later on, at beginning of Section 4 below, we recall a few more important background results from Nevanlinna theory, frequently applied in considering complex differential equations.

For more details, several standard textbooks may be found. In our present list of references, [98] and [107] may be useful.

2.1. *Homogeneous linear differential equations with polynomial coefficients*

In studying global properties of solutions of linear differential equations in the complex plane, the non-trivial model case is

$$f'' + A(z) f = 0. \tag{2.1.1}$$

In this section, we assume that the coefficient $A(z) = c_n z^n + \cdots + c_0$ is a non-constant polynomial of degree n, $c_n \neq 0$. Then it is a classical result that certain symmetrically spaced radii from the origin essentially describe the zeros of non-trivial solutions of (2.1.1), see e.g. Gundersen [52], pp. 279–280, and [76], Chapter 7.4:

PROPOSITION 2.1.1. *Consider a differential equation* (2.1.1) *with a non-constant polynomial coefficient* $A(z)$ *of degree* n. *Denote* $\alpha = \frac{n+2}{2}$. *For* $0 < \delta < \frac{\pi}{2\alpha}$ *and* $j = 0, \ldots, n+1$, *consider the sectors*

$$S_j(\delta) := \left\{ z;\ \frac{j\pi - \arg c_n}{\alpha} + \delta \leqslant \arg z \leqslant \frac{(j+2)\pi - \arg c_n}{\alpha} - \delta \right\}. \tag{2.1.2}$$

If now a non-trivial solution of (2.1.1) *has infinitely many zeros in a sector* $S_j(\delta)$, *then for any* $\varepsilon > 0$, *all but finitely many of these zeros lie in the sector*

$$V_j(\varepsilon) := \left\{ z;\ \left| \arg z - \frac{2(j+1)\pi - \arg c_n}{n+2} \right| < \varepsilon \right\}. \tag{2.1.3}$$

Moreover, the non-integrated counting function for the zeros of f in the sector $V_j(\varepsilon)$ is

$$n_j(r,1/f)=\bigl(1+\mathrm{o}(1)\bigr)\frac{\sqrt{c_n}}{n\alpha}r^{\alpha}. \tag{2.1.4}$$

This proposition enables us to obtain fairly good estimates for the growth and zero distribution of non-trivial solutions f of (2.1.1). By the Wiman–Valiron theory, see e.g. [98], all non-trivial solutions are of order $\rho(f)=\alpha:=\frac{n+2}{2}$. To describe their growth and value distribution, we denote by $p(f)$ the number of sectors $V_j(\varepsilon)$ with the property that for some $\varepsilon>0$, the non-trivial solution f of (2.1.1) has only finitely many zeros in $V_j(\varepsilon)$. Clearly, $0\leqslant p(f)\leqslant n+2$. We now obtain, see [52], Theorems 5 and 6, the following asymptotic equalities:

THEOREM 2.1.2. *Given a non-trivial solution f of* (2.1.1), *and using the notations described above, $p(f)$ is an even number and*

$$n(r,1/f)=\bigl(1+\mathrm{o}(1)\bigr)\frac{2\alpha-p(f)}{\pi\alpha}\sqrt{|c_n|}\,r^{\alpha}, \tag{2.1.5}$$

$$N(r,1/f)=\bigl(1+\mathrm{o}(1)\bigr)\frac{2\alpha-p(f)}{\pi\alpha^2}\sqrt{|c_n|}\,r^{\alpha}, \tag{2.1.6}$$

$$T(r,f)=\bigl(1+\mathrm{o}(1)\bigr)\frac{4\alpha-p(f)}{2\pi\alpha^2}\sqrt{|c_n|}\,r^{\alpha}, \tag{2.1.7}$$

$$\log M(r,f)=\bigl(1+\mathrm{o}(1)\bigr)\frac{\sqrt{|c_n|}}{\alpha}\,r^{\alpha}. \tag{2.1.8}$$

Moreover, we have for the deficiency of zeros of f;

$$\delta(0,f)=\Delta(0,f)=\frac{p(f)}{4\alpha-p(f)}. \tag{2.1.9}$$

REMARK. Equation (2.1.1) with $\deg A=n$ possesses $m\geqslant 2$ pairwise linearly independent solutions $f_1,\dots,f_m$ such that $p(f_j)\geqslant 2$ for $j=1,\dots,m$ and $\sum_{j=1}^{m}p(f_j)=2(n+2)$. Moreover, any non-trivial solution f of (2.1.1) that is not a constant multiple of some f_j, $j=1,\dots,m$, has $p(f)=0$. Hence, most of the non-trivial solutions f have $p(f)=0$. See [52], pp. 281–283, for more details. Finally, observe that the maximum modulus of f is independent of $p(f)$.

Because of the symmetric spacing of the critical rays described in Proposition 2.1.1, and the fact that $p(f)$ is even, it is not surprising that the number of non-real zeros of a non-trivial solution f is maximal in most cases, see [52]:

THEOREM 2.1.3. *Given two linearly independent solutions f_1,f_2 of* (2.1.1), *at least one of f_1,f_2 has the property that its sequence of non-real zeros has exponent of convergence equal to* $(n+2)/2$. *Moreover, if the coefficient polynomial $A(z)$ in* (2.1.1) *is of degree $n=2+4k$ for a non-negative integer k, then any non-trivial solution f either has finitely* *many zeros only, or the exponent of convergence of the non-real zero-sequence of* f *is* $(n+2)/2$.

Combining [52], Theorem 3 and Lemma 5, see also [147], Theorem 1.1, the following conclusion appears:

THEOREM 2.1.4. *If Eq.* (2.1.1) *admits a non-trivial solution* f *with infinitely many real zeros, then* $A(z)$ *is a real polynomial* (*i.e. real on the real axis*), *and* f *is a constant multiple of a real solution of* (2.1.1).

By the preceding result, it makes sense to call special attention to the case when $A(z)$ is a real polynomial. In this direction, Eremenko and Merenkov [41] proved the following interesting results recently:

THEOREM 2.1.5. *For each* $n \geqslant 1$, *there exists Eq.* (2.1.1) *with a real polynomial* $A(z)$ *of degree* n *and a solution* f *of* (2.1.1) *such that all zeros of* f *are real. Concerning different values of* n,

(a) *if* $n = 0 \pmod 4$, *then the zero-set of* f *is either finite or it is unbounded from above and below,*
(b) *if* $n = 2 \pmod 4$, *then* f *has finitely many zeros only and*
(c) *if* n *is odd, then* f *has infinitely many zeros all of which lie on a ray of the real axis.*

The proof of this result in [41] makes use of the graph theory (Speiser graphs).

EXAMPLE. (See [52].) The classical Airy differential equation

$$f'' - zf = 0$$

admits a solution whose zeros are all real and negative, namely the standard Airy function $Ai(z)$, compare Theorem 2.1.5(c). Clearly, $p(Ai) = 2$. Therefore, by Theorem 2.1.2,

$$N(r, 0, Ai) = \bigl(1 + \mathrm{o}(1)\bigr)\frac{4}{9\pi}r^{3/2}, \qquad T(r, Ai) = \bigl(1 + \mathrm{o}(1)\bigr)\frac{8}{9\pi}r^{3/2}$$

and

$$\log M\bigl(r, Ai\bigr) = \bigl(1 + \mathrm{o}(1)\bigr)\frac{2}{3}r^{3/2}.$$

For an analysis of a generalized Airy differential equation

$$f'' - z^n f = 0,$$

see [54].

REMARK. Proposition 2.1.1 depicts what is called the *finite oscillation property*, see [7], p. 266: There exist finitely many rays $\arg z = \theta_j$, $j = 1, \dots, m$, such that for any $\varepsilon > 0$, all but finitely many zeros of any non-trivial solution of a linear differential equation

$$f^{(n)} + p_{n-1}(z) f^{(n-1)} + \cdots + p_0(z) f = 0 \tag{2.1.10}$$

lie in the union of the sectors $|\arg z - \theta_j| < \varepsilon$, $j = 1, \dots, m$. On the other hand, we say that a linear differential equation possesses the *global oscillation property*, if there is a non-trivial solution f such that for any ray $\arg z = \theta$ and any $\varepsilon > 0$, f has infinitely many zeros in the sector $|\arg z - \theta| < \varepsilon$. By Proposition 2.1.1, the finite oscillation property holds for the basic second order differential equation (2.1.1) with a polynomial coefficient $A(z)$. However, the finite oscillation property does not hold in general in the higher order case (2.1.10). For instance, equation

$$f^{(n)} + z^2 f'' + z f' + f = 0, \quad n > 2,$$

possesses the global oscillation property, see [6], p. 37. In fact, given any Eq. (2.1.10) with polynomial coefficients, it can be shown that it has either the finite oscillation property, or the global oscillation property, see [8], Theorem 1.

Concerning homogeneous linear differential equations of the form (2.1.10) with $n \geqslant 2$ and with polynomial coefficients such that $p_0(z)$ does not vanish identically, it is well known that all solutions f of Eq. (2.1.10) are entire functions of finite rational order. Moreover, denoting $d_j := \deg p_j$, if p_j does not vanish, and $d_j = -\infty$ otherwise, we have that

$$\rho(f) \leqslant \lambda := 1 + \max_{0 \leqslant j \leqslant n-1} \frac{d_j}{n-j} \tag{2.1.11}$$

for all solutions of (2.1.10). These are classical results usually proved by the Wiman–Valiron theory and, to determine the possible rational orders, the Newton–Puiseux diagram, see [98]. However, the list of possible rational orders may be obtained by simple arithmetic with the degrees of polynomial coefficients of (2.1.10), as shown by Gundersen, Steinbart and Wang in [56]. To recall this reasoning, we first determine a strictly decreasing finite sequence $s_1, \dots, s_p$ of non-negative integers by defining

$$s_0 = n, \tag{2.1.12}$$

$$s_1 := \min\left\{ j; \frac{d_j}{n-j} = \max_{0 \leqslant m \leqslant n-1} \frac{d_m}{n-m} \right\} \leqslant n-1 \tag{2.1.13}$$

and then, inductively,

$$s_{j+1} := \min\left\{ k; \frac{d_k - d_{s_j}}{s_j - m} = \max_{0 \leqslant m \leqslant s_j} \frac{d_m - d_{s_j}}{s_j - m} > -1 \right\}. \tag{2.1.14}$$

Clearly, this process terminates after a finite number $p \leqslant n$ of steps. We then define, for $j = 1, \dots, p$,

$$\alpha_j := 1 + \frac{d_{s_j} - d_{s_{j-1}}}{s_{j-1} - s_j} > 0, \tag{2.1.15}$$

where, of course, $d_{s_0} = 0$. We are now ready to state

THEOREM 2.1.6. *Concerning the growth of solutions of* (2.1.10), *the following assertions hold*:

(a) *Equation* (2.1.10) *possesses at most* s_p *linearly independent polynomial solutions*.

(b) *If* f *is a transcendental solution, then* $\rho(f) = \alpha_j$ *for some* j, $1 \leqslant j \leqslant p$. *Moreover, if* $s_1 \geqslant 1$ *and* $p \geqslant 2$, *then*

$$\alpha_1 > \alpha_2 > \cdots > \alpha_p \geqslant \frac{1}{s_1 - s_p} \geqslant \frac{1}{s_1} \geqslant \frac{1}{n-1},$$

and if $s_1 = 0$, *then all non-trivial solutions* f *are of order* $\rho(f) = 1 + d_0/n$.

(c) *For any* $j = 1, \dots, p$, *there exist at most* s_j *linearly independent solutions* f *of order* $\rho(f) < \alpha_j$. *Also, there always exists a solution* f *of order* $\rho(f) = \lambda = 1 + \max_{0 \leqslant j \leqslant n-1} \frac{d_j}{n-j}$.

(d) *If* $\{f_1, f_2, \dots, f_n\}$ *is any fundamental set of solutions of* (2.1.10), *then*

$$\sum_{j=1}^{n} \rho(f_j) \geqslant n + d_0.$$

For a collection of examples showing the sharpness of the preceding theorem, see [56], pp. 1240–1246.

The frequency of zeros of solutions of (2.1.10) with polynomial coefficients has been somewhat studied since 1950's; we refer here to a number of papers by Pöschl, Wittich, Frank, Brüggemann and Steinmetz. However, the recent papers by Wang [186] and Steinbart [168] offer the most complete understanding of this topics until now. To describe these recent results, we first recall the real numbers $s_0, \dots, s_p$ and $\alpha_1, \dots, \alpha_p$ defined by the degrees of the polynomial coefficients of (2.1.10) as described above. Observe that we then have

$$d_{s_j} - d_{s_{j-1}} = (\alpha_j - 1)(s_{j-1} - s_j).$$

Let now A_j be the leading coefficient of $p_j = A_j z^{d_j} + \cdots$, and define

$$A^{\star}_{k,m} := \begin{cases} A_k & \text{if } d_k = d_{s_{m-1}} + (\alpha_m - 1)(s_{m-1} - k), \\ 0 & \text{otherwise} \end{cases} \tag{2.1.16}$$

and

$$A^{\sharp}_{k} := \begin{cases} A_k & \text{if } \frac{d_k}{n-k} = \max_{0 \leqslant j \leqslant n-1} \frac{d_j}{n-j}, \\ 0 & \text{otherwise.} \end{cases} \tag{2.1.17}$$

We then define the following polynomials corresponding to (2.1.16) and (2.1.17) as

$$H_m(t) := \sum_{k=0}^{s_m-1} A^{\star}_{k,m} t^k, \quad 1 \leqslant m \leqslant p, \tag{2.1.18}$$

and

$$H^{\sharp}(t) := t^n + \sum_{k=0}^{n-1} A^{\sharp}_k t^k. \tag{2.1.19}$$

We may now express the key results in [186] and [168] as follows:

THEOREM 2.1.7. *Concerning the frequency of zeros of solutions of* (2.1.10), *the following assertions hold*:

(a) *If f is a non-trivial solution such that $\rho(f)$ is not an integer, then f has infinitely many zeros and $\rho(f) = \lambda(f)$.*

(b) *If f is a transcendental solution of order $\rho(f) = \alpha_m \in \mathbb{N}$ for some m, $1 \leqslant m \leqslant p$, and if all non-zero roots of equation $H_m(t) = 0$ are simple, then either $\rho(f) = \lambda(f)$, or f has finitely many zeros only.*

(c) *Suppose at least one of the coefficients of* (2.1.10) *is non-constant. Then the following properties are equivalent*:

  (1) *Equation* (2.1.10) *admits a fundamental solution set $\{f_1, \ldots, f_n\}$ such that $\lambda(f_j) < \rho(f_j)$, $j = 1, \ldots, n$.*

  (2) *Equation* (2.1.10) *admits a fundamental solution set $\{f_1, \ldots, f_n\}$ such that*

$$\max_{1\leqslant j\leqslant n} \lambda(f_j) < \lambda = 1 + \max_{0\leqslant j\leqslant n-1} \frac{d_j}{n-j}.$$

  (3) *The polynomial $H^{\sharp}(t)$ takes the form $H(t) = (t+b)^n$ for some non-zero constant b.*

For some examples illuminating the preceding theorem, see [168], pp. 368–370.

REMARK. It seems quite likely that multiple roots of $H_m(t) = 0$, resp. of $H^{\sharp}(t) = 0$, correspond to subsets of the fundamental solution set $\{f_1, \ldots, f_n\}$ such that the solutions f in these subsets satisfy $\lambda(f) < \rho(f)$. As far as we know, there is no explicit proof for this claim yet. See, however, Theorem 2.5.5 below.

2.2. *Second order homogeneous linear differential equations with entire coefficients*

Looking at the non-trivial model case (2.1.1) with a transcendental entire coefficient $A(z)$, it immediately follows from the logarithmic derivative lemma that $\rho(f) = \infty$. Therefore, the key problem here is to consider the frequency of zeros of solutions of (2.1.1). This topic has been under active research since 1982, see [15].

The key idea to consider the zero frequency of solutions of (2.1.1) with $A(z)$ transcendental entire, is to make use of the product E of two linearly independent solutions f_1, f_2. By the classical Abel identity, we know that the Wronskian $W(f_1, f_2)$ is a non-zero constant. Therefore, we may normalize it to be equal to 1. Then it is routine to check that

$$4A = \left(\frac{E'}{E}\right)^2 - \frac{1}{E^2} - 2\frac{E''}{E}. \tag{2.2.20}$$

Since the zero-sets of f_1 and f_2 are distinct, we have for the exponent of convergence of the zeros of E that

$$\lambda(E) = \max\bigl(\lambda(f_1), \lambda(f_2)\bigr).$$

Then the basic results from [15], complemented with an improvement due to Shen [154] and Rossi [146] for the case $\rho(A) = 1/2$, may be written as

THEOREM 2.2.1. *Concerning the frequency of zeros of solutions of* (2.1.1) *with* $A(z)$ *transcendental entire, the following assertions hold*:

(a) *Suppose* $\rho(A) < \infty$ *but is not a natural number. If* $\rho(A) \leqslant 1/2$, *then* $\lambda(E) = \infty$; *if* $\rho(A) < 1$, *then* $\lambda(E) > 1$; *and if* $\rho(A) \geqslant 1$, *then* $\lambda(E) \geqslant \rho(A)$.

(b) *Suppose next that* $\lambda(A) < \rho(A)$ (*which implies by the Hadamard factorization that* $\rho(A)$ *is a natural number or infinite*). *Then the exponent of convergence* $\lambda(f)$ *of the zero-sequence of an arbitrary non-trivial solution* f *satisfies* $\lambda(f) \geqslant \rho(A)$.

(c) *If* $\bar{\lambda}(A) < \rho(A)$, *then* $\lambda(E) \geqslant \rho(A)$.

(d) *There exist two linearly independent zero-free solutions* f_1, f_2 *of* (2.1.1) *in the complex plane if and only if* $A(z)$ *is of the form*

$$-4A(z) = h'(z)^2 + \phi'(z)^2 - 2\phi''(z)$$

where ϕ *a non-constant entire function and* h *a primitive of* $\exp(\phi)$.

(e) *If* $\lambda(E) = \max(\lambda(f_1), \lambda(f_2)) < \infty$, *then* $\lambda(f) = \infty$ *for all solutions* f *of* (2.1.1) *not being of the form* αf_1 *or* αf_2 *for some* $\alpha \in \mathbb{C}$.

PROOF. As a typical example of applying the product E of two linearly independent solutions of (2.1.1), we prove the last assertion of (a). If $\lambda(E) < \rho(A)$, then (2.2.20) easily implies that $\rho(E) \leqslant \rho(A)$. Since $\rho(A)$ is not a natural number, the Hadamard product representation implies that $\lambda(E) = \rho(A)$. ☐

EXAMPLE. As an example of the case when $\rho(A)$ is a natural number, we collect here a few facts related to equation

$$f'' + \bigl(e^{P(z)} + Q(z)\bigr) f = 0, \tag{2.2.21}$$

where P is polynomial of degree $\deg P = \lambda > 0$ and Q is an entire function of order $\rho(Q) < \lambda$. Then the following properties are valid:

(1) If (2.2.21) admits a non-trivial solution f such that $\lambda(f) < \lambda$, then f has no zeros, $Q = -\frac{1}{16}(P')^2 + \frac{1}{4}P''$ is a polynomial and there is another zero-free solution of (2.2.21), linearly independent of f.

(2) If $Q(z) \equiv 0$, then $\lambda(f) = \infty$ for all non-trivial solutions f of (2.2.21).

(3) In the special case of $f'' + (e^z - K)f = 0$, $K \in \mathbb{C}$, a non-trivial solution f with $\lambda(f) < \infty$ exists if and only if $K = q^2/16$ for an odd integer q. In this case, the equation admits two linearly independent solutions such that for their product E, $\lambda(E) = 0$, if $|q| = 1$ and $\lambda(E) = 1$ otherwise.

Theorem 2.2.1, together with a collection of examples to be found in the literature, prompted the following conjecture, known as the Bank–Laine conjecture (BL-conjecture for short), implicitly contained in [15]:

CONJECTURE. *Let* $A(z)$ *be transcendental entire of finite order of growth* ρ. *If* f_1, f_2 *are two linearly independent solutions of* (2.1.1) *such that* $\max(\lambda(f_1), \lambda(f_2) < \infty$, *then* ρ *is a natural number.*

In its full generality, the conjecture remains open. Due to the wide interest this problem has implied, a few remarks follow. Recalling (2.2.20), it is not difficult to see that all zeros of f_1, f_2 and $E := f_1 f_2$ are simple, and $E'(z_0) = \pm 1$ at all zeros z_0 of E, provided the Wronskian $W(f_1, f_2)$ has been normalized to $W(f_1 f_2) = 1$. This condition is known as the BL-condition and any entire function E satisfying the BL-condition is called a BL-function. To resolve the BL-conjecture, it is sufficient to show that whenever E is a BL-function of finite order, then the corresponding coefficient function $A(z)$ of equation (2.1.1), determined by (2.2.20), is of an integer order of growth. A number of examples of BL-functions fall in two classes of functions: (1) Entire functions of type $P(z)e^{Q(z)}$, where P is a polynomial with simple zeros only, and Q is a (non-constant) polynomial and (2) entire functions of type $P(e^{\alpha z})e^{\beta z}$, where P is a polynomial with simple zeros only, and α, β are constants. However, not all known BL-functions of finite order belong in these two function classes as shown by Langley, see [112,113] and [114]. It has also been shown recently by Drasin and Langley, see [35], that there exists a Bank–Laine function E, associated with a transcendental coefficient function $A(z)$ determined by (2.2.20), such that for any given positive integer n, $n \leqslant \rho(E) \leqslant \lambda(E) < \infty$. For more details about the BL-conjecture, see [109].

The BL-conjecture has been very much in the background to direct research concerning Eq. (2.1.1) during the last quarter of century. A special situation having attracted a lot of attention is the case when $A(z)$ is a periodic function. The key problem here has been to explain when such an equation admits a non-trivial solution f with a few zeros in the sense of $\lambda(f) < \infty$. The first paper in this line was [16], to our knowledge. Recently, Chiang [29] improved the results in [16]. To recall the key results in these papers, suppose that $A(z)$ is of period $2\pi\mathrm{i}$. Then we may write

$$A(z)=B(\mathrm{e}^z), \qquad B(\zeta)=\sum_{j=k}^{l}K_j\zeta^j=g(\zeta)+h(1/\zeta),$$

where $K_kK_l\neq 0$, $l\geqslant k$, and $g(\zeta), h(1/\zeta)$ are entire functions. Making the transformation $\zeta\mapsto 1/\zeta$, if needed, we may assume that $l\geqslant 0$.

THEOREM 2.2.2. (See [29], Proposition 1.) *Given a differential equation* (2.1.1), *where* $A(z)=B(\mathrm{e}^z)$ *is a rational function of* e^z, *write* $B(\zeta)=\sum_{j=k}^{l}K_j\zeta^j$, $K_lK_k\neq 0$, *and assume that* $\lambda(f)<\infty$ *for a non-trivial solution* f. *Then the following assertions hold*:

(1) *If* l *is odd and positive, then* $k=0$ *and* f *has the following representation*:

$$f(z)=\psi(\mathrm{e}^{z/2})\exp\left(\sum_{j=0}^{l}d_j\mathrm{e}^{jz/2}+dz\right),$$

where d, d_j *are constants and* $\psi(\zeta)$ *is a polynomial with simple zeros only. Moreover,* $d_j=0$ *for all* $j>0$ *even.*

(2) *If* l *is even and positive, then* k *is even as well, and*

$$f(z)=\psi(\mathrm{e}^{z})\exp\left(\sum_{j=-k/2}^{l/2}d_j\mathrm{e}^{jz}+dz\right),$$

where again d, d_j *are constants and* $\psi(\zeta)$ *is a polynomial with simple zeros only.*

By the presentations for $f(z)$ in Theorem 2.2.2, it follows that f is zero-free if and only if $\lambda(f)=0$. In this special situation, more detailed representations for $f(z)$ may be obtained, see [29], Theorems 1, 2 and 3.

Continuing to the more general case when $A(z)$ is a non-constant periodic entire function of period $2\pi\mathrm{i}$ and transcendental in e^z, we obtain [16]:

THEOREM 2.2.3. *Let* $A(z)$ *be a non-constant periodic entire function such that* $A(z)=B(\mathrm{e}^z)$, *where* $B(\zeta)$ *is analytic in* $\mathbb{C}\setminus\{0\}$, *and assume that* f *is a non-trivial solutions of* (2.1.1) *such that* $\lambda(f)<\infty$. *Then* f *has the representation*

$$f(z)=\mathrm{e}^{dz}H(\mathrm{e}^{z/q})\exp\bigl(g(\mathrm{e}^{z/q})\bigr),$$

where (1) d *is a complex number,* (2) $q=1$ *or* $q=2$ *depending whether* $f(z)$ *and* $f(z+2\pi\mathrm{i})$ *are linearly dependent or not,* (3) $H(\zeta)$ *and* $g(\zeta)$ *are analytic in* $\mathbb{C}\setminus\{0\}$, *and* (4) $g(\zeta)$ *has at most a pole at* $\zeta=\infty$, *resp.* $\zeta=0$, *if and only if* $B(\zeta)$ *has at most a pole at* $\zeta=\infty$, *resp.* $\zeta=0$. *Moreover, letting* ρ_∞, *resp.* ρ_0, *denote the local order at* ∞, *resp. at* 0, *we have* $\rho_0(H)=\rho_\infty(H)=0$, $\rho_0(g)=\rho_0(B)$ *and* $\rho_\infty(g)=\rho_\infty(B)$.

For additional results concerning the case $A(z) = B(\mathrm{e}^z)$, where $A(z)$ is transcendental in e^z, see [30].

2.3. *Higher order homogeneous linear differential equations*

We now proceed to considering higher order homogeneous linear differential equations

$$L(f) := f^{(n)} + a_{n-1}(z) f^{(n-1)} + \cdots + a_0(z) f = 0 \tag{2.3.22}$$

with entire coefficients. Since (2.3.22) may easily be reduced to

$$f^{(n)} + a_{n-2}(z) f^{(n-1)} + \cdots + a_0(z) f = 0, \tag{2.3.23}$$

a substantial part below will be formulated for (2.3.23). Contrary to the normalized second-order case of (2.1.1), it may now appear, even in the second order case, that two solutions may be of substantially different growth. The first classical result in this direction is due to Frei in [44]:

THEOREM 2.3.1. *Let a_j be the last transcendental function in the coefficient sequence $a_0, \ldots, a_{n-1}$ of* (2.3.22). *Then Eq.* (2.3.22) *possesses at most j linearly independent solutions of finite order.*

REMARK. Combining Theorem 2.3.1 with (2.1.11) we conclude that all solutions of (2.3.22) are of finite order of growth if and only if all coefficients of (2.3.22) are polynomials, see Wittich [190].

REMARK. In the special case of $n = 2$, Theorem 2.3.1 implies that all non-trivial solutions are of infinite order, provided a_0 is transcendental and a_1 rational. More generally, the same conclusion follows in a variety of situations, where a_0 is dominant. A nice example of this type has been proved by Kwon in [106]:

THEOREM 2.3.2. *Given two constants $\alpha, \beta > 0$, and a set E in the real axis of strictly positive upper density, suppose that the entire functions a_1, a_0 satisfy the growth conditions*

$$\left|a_1(z)\right| \leqslant \exp\bigl(\mathrm{o}(1)|z|^\beta\bigr), \qquad \left|a_0(z)\right| \geqslant \exp\bigl(\bigl(1 + \mathrm{o}(1)\bigr)\alpha|z|^\beta\bigr)$$

as $|z| \to \infty$, $|z| \in E$. Then all non-trivial solutions of

$$f'' + a_1(z) f' + a_0(z) f = 0$$

are of infinite order.

For another result of this type, see Theorem 2.3.6 below.

Making use of the notion of an iterated order,

$$\rho_j(z) := \limsup_{r\to\infty} \frac{\log_j T(r, f)}{\log r}, \tag{2.3.24}$$

where $\log_1(r) := \log r$, $\log_j(r) := \log\log_{j-1}(r)$, we may perform a more detailed analysis of the growth of solutions of (2.3.22), see [102]. To this end, we define the *finiteness degree of growth* $i(f)$ of a meromorphic function f as $i(f) = 0$ for rational functions, $i(f) := \min\{j \in \mathbb{N}; \rho_j(f) < \infty\}$, and $i(f) = \infty$ otherwise. Concerning the linear differential operator $L(f)$ with entire coefficients, we define

$$\begin{aligned}
&\delta(L) := \max\bigl\{i(f); L(f) = 0\bigr\},\\
&\gamma_j(L) := \max\bigl\{\rho_j(f); L(f) = 0\bigr\}, \quad j \in \mathbb{N},\\
&p(L) := \max\bigl\{i(a_j); j = 0, \dots, n-1\bigr\}.
\end{aligned}$$

Provided $0 < p := p(L) < \infty$, we also define

$$\kappa(L) := \max\bigl\{\rho_p(a_j); j = 0, \dots, n-1\bigr\}.$$

Using these notations, we have

THEOREM 2.3.3. *If* $0 < p < \infty$, *then* $\delta(L) = p + 1$ *and* $\gamma_{p+1}(L) = \kappa(L)$. *Moreover, if* a_j *be the last coefficient in the sequence* $a_0, \dots, a_{n-1}$ *such that* $i(a_j) = p$, *then* (2.3.22) *possesses at most* j *linearly independent solutions* f *such that* $i(f) \leqslant p$.

PROOF. The key idea of the proof makes use of the standard order reduction procedure of linear differential equations, combined with the generalized logarithmic derivative lemma, see [102], Lemma 1.3: Given a meromorphic function f such that $i(f) = p \geqslant 1$ and $\rho_p(f) = \rho$, then for any $\varepsilon > 0$ and any natural number k, $m(r, f^{(k)}/f) = O(\exp_{p-2} r^{\rho+\varepsilon})$ outside of a possible exceptional set of finite linear measure. □

In the general case of (2.3.22) with $n \geqslant 2$, the preceding theorems leave open the problem of determining the situations when all solutions of (2.3.22) are, say, of infinite order. Such a situation typically appears, if one of the coefficients is dominating in the sense of growth, see [110]:

THEOREM 2.3.4. *Let* $a_0(z), \dots, a_{n-1}(z)$ *be entire functions such that for some integer* s, $1 \leqslant s \leqslant n-1$, *we have* $\rho_p(a_j) < \rho_p(a_s) \leqslant \infty$ *for all* $j \neq s$. *Then every transcendental solution* f *of* (2.3.22) *satisfies* $\rho_p(f) \geqslant \rho_p(a_s)$.

However, one may obtain similar results if one of the coefficients is dominant just almost everywhere only, in certain sense. Recently, a number of papers of such type have been written. Prototypes of such results may be found in [53]:

THEOREM 2.3.5. *Let* $a_0(z) \not\equiv 0$, $a_1(z)$ *be entire functions such that for some real constants* $\alpha > 0$, $\beta > 0$ *and* $\theta_1 < \theta_2$ *we have*

$$|a_1(z)| \geqslant \exp\bigl((1 + \mathrm{o}(1))\alpha |z|^\beta\bigr)$$

and

$$|a_0(z)| \leqslant \exp\bigl(\mathrm{o}(1)|z|^\beta\bigr)$$

as $z \to \infty$ *in the sector* $S(0) := \{\theta = \arg z; \theta_1 \leqslant \theta \leqslant \theta_2\}$. *Given* $\varepsilon > 0$ *small enough, consider the sector* $S(\varepsilon) := \{\theta = \arg z; \theta_1 + \varepsilon \leqslant \theta \leqslant \theta_2 - \varepsilon\}$. *If* f *is a non-trivial solution of*

$$f'' + a_1(z) f' + a_0(z) f = 0$$

of finite order, then the following conditions hold:

(i) *There exists a constant* $b \neq 0$ *such that* $f(z) \to b$ *as* $z \to \infty$ *in* $S(\varepsilon)$. *More precisely,*

$$|f(z) - b| \leqslant \exp\bigl(-(1 + \mathrm{o}(1))\alpha |z|^\beta\bigr).$$

(ii) *For each integer* $k \geqslant 1$,

$$|f^{(k)}(z)| \leqslant \exp\bigl(-(1 + \mathrm{o}(1))\alpha |z|^\beta\bigr)$$

as $z \to \infty$ *in* $S(\varepsilon)$.

This result, combined with the classical Phragmén–Lindelöf principle, applies now to prove

THEOREM 2.3.6. *Let* $a_0(z) \not\equiv 0$, $a_1(z)$ *be entire functions, and let* $\alpha > 0$ *and* $\beta > 0$ *be constants such that* $\rho(a_0) < \beta$. *Suppose that for any given* $\varepsilon > 0$, *there exist two finite collections of real numbers that satisfy* $\phi_1 < \theta_1 < \phi_2 < \theta_2 < \cdots < \phi_n < \theta_n < \phi_{n+1} = \phi_1 + 2\pi$, *and* $\sum_{j=1}^{n} (\phi_{j+1} - \phi_j) < \varepsilon$, *such that*

$$|a_1(z)| \geqslant \exp\bigl((1 + \mathrm{o}(1))\alpha |z|^\beta\bigr)$$

as $z \to \infty$ *in each of the sectors* $\phi_j \leqslant \arg z \leqslant \theta_j$, $j = 1, \ldots, n$. *Then all non-trivial solutions* f *of*

$$f'' + a_1(z) f' + a_0(z) f = 0$$

are of infinite order of growth.

Applying a certain type of nested induction process, see [110], the preceding theorems may be extended to (2.3.22), in the form that the dominating coefficient may be any one of the intermediate coefficients:

THEOREM 2.3.7. *Let* $\theta_1 < \theta_2$ *be given to fix the sector* $S(0)$ *as in Theorem* 2.3.5, *and let* $\delta > 0$ *be any real number such that* $n\delta < 1$. *Suppose that* $a_0(z) \not\equiv 0, a_1(z), \ldots, a_{n-1}(z)$ *are entire functions such that for real constants* $\alpha > 0$, $\beta > 0$, *we have for some* s, $1 \leqslant s \leqslant n-1$, *that*

$$\left|a_s(z)\right| \geqslant \exp\bigl((1+\delta)\alpha|z|^{\beta}\bigr),$$

$$\left|a_j(z)\right| \leqslant \exp\bigl(\delta\alpha|z|^{\beta}\bigr)$$

for all $j = 0, \ldots, s-1, s+1, \ldots, n-1$ *whenever* $|z|$ *is large enough in the sector* $S(0)$. *Given* $\varepsilon > 0$ *small enough, if* f *is a transcendental solution of finite order* ρ *of Eq.* (2.3.22), *then the following conditions hold*:

(i) *There exists* j, $0 \leqslant j \leqslant s-1$, *and a constant* $b_j \neq 0$ *such that* $f^{(j)} \to b_j$ *as* $z \to \infty$ *in the sector* $S(\varepsilon)$. *More precisely,*

$$\left|f^{(j)}(z) - b_j\right| \leqslant \exp\bigl(-(1-n\delta)\alpha|z|^{\beta}\bigr)$$

in $S(\varepsilon)$, *provided* $|z|$ *is large enough.*

(ii) *For each integer* $m \geqslant j+1$,

$$\left|f^{(m)}(z)\right| \leqslant \exp\bigl(-(1-n\delta)\alpha|z|^{\beta}\bigr)$$

in $S(3\varepsilon)$ *for all* $|z|$ *large enough.*

THEOREM 2.3.8. *Let* $a_0(z) \not\equiv 0, a_1(z), \ldots, a_{n-1}(z)$ *be entire functions, let* $\alpha > 0$, $\beta > 0$ *be given constants, let* $\delta > 0$ *be a real number such that* $n\delta < 1$ *and let* s *be an integer such that* $1 \leqslant s \leqslant n-1$. *Suppose that* $\rho(a_s) < \beta$ *for all* $j \neq s$ *and that for any given* $\varepsilon > 0$, *there exist two finite collections of real numbers that satisfy* $\phi_1 < \theta_1 < \phi_2 < \theta_2 < \cdots < \phi_m < \theta_m < \phi_{m+1} = \phi_1 + 2\pi$ *such that* $\sum_{j=1}^{m}(\phi_{j+1} - \phi_j) < \varepsilon$ *and*

$$\left|A_s(z)\right| \geqslant \exp\bigl((1+\delta)\alpha|z|^{\beta}\bigr)$$

as $z \to \infty$ *in each of the sectors* $\phi_j \leqslant \arg z \leqslant \theta_j$, $j = 1, \ldots, m$. *Then every transcendental solution* f *of* (2.3.22) *is of infinite order.*

Another result in the same line is due to Yang in [193], as a generalization of the corresponding theorem when $n = 2$:

THEOREM 2.3.9. *Let* E *be a set in the positive real axis of strictly positive upper density, and suppose that for some constants* $0 \leqslant \beta < \alpha$ *and* $\mu > 0$, *we have*

$$\left|a_0(z)\right| \geqslant \exp\bigl(\alpha|z|^{\mu}\bigr)$$

and

$$\left|a_j(z)\right| \leqslant \exp\bigl(\beta|z|^{\mu}\bigr),$$

for $j = 1, \dots, n-1$ *as* $|z| \to \infty$, $|z| \in E$. *Then all non-trivial solutions of* (2.3.22) *are of infinite order and, in fact,* $\rho_2(f) \geqslant \mu$.

Proceeding now to the zero distribution of solutions, the present research status is much more scattered than it is in the special second order case (2.1.1), even in the reduced case of (2.3.23). The product $E := f_1 \cdots f_n$ still remains important, but no counterpart of the identity (2.2.20) is available in this more general situation. However, Bank and Langley were able to prove in [18] several results corresponding to previous ones in the case of (2.1.1):

THEOREM 2.3.10. *Suppose that* $n \geqslant 3$ *in Eq.* (2.3.23) *and that the coefficients* $a_0(z), \dots, a_{n-2}(z)$ *are entire functions of finite order. Moreover, suppose that* (2.3.23) *admits a solution base* $f_1, \dots, f_n$ *each with* $\lambda(f_j) < \infty$. *Then their product* E *is of finite order as well.*

THEOREM 2.3.11. *Suppose that* $n \geqslant 3$ *in Eq.* (2.3.23) *and that the coefficients* $a_0(z), \dots, a_{n-2}(z)$ *are entire functions. Moreover, assume that* (i) a_0 *is transcendental of order* $\rho(a_0) < 1/2$ *and* (ii) $\rho(a_j) < \rho(a_0)$ *for* $j = 1, \dots, n-2$, *if* $\rho(a_0) > 0$, *while* $a_1, \dots, a_{n-2}$ *are polynomials, if* $\rho(a_0) = 0$. *Then Eq.* (2.3.23) *cannot admit two linearly independent solutions* f_1, f_2 *each with* $\lambda(f_j) < \infty$.

THEOREM 2.3.12. *Suppose that* $n \geqslant 3$ *in Eq.* (2.3.23) *and that the coefficients* $a_0(z), \dots, a_{n-2}(z)$ *are entire functions of finite order such that* $\rho(a_j) < \rho := \rho(a_0)$ *for all* $j = 1, \dots, n-2$. *Moreover, suppose that Eq.* (2.3.23) *admits a solution base* $f_1, \dots, f_n$ *each with* $\lambda(f_j) < \infty$. *Then* ρ *is a natural number and* $\rho(E) = \rho$.

THEOREM 2.3.13. *Suppose that* $n \geqslant 3$ *in Eq.* (2.3.23) *and that the coefficients* $a_0(z), \dots, a_{n-2}(z)$ *are entire functions. Moreover, assume that* (i) a_0 *is transcendental of order* $\rho(a_0) < 1/2$ *and* (ii) $\rho(a_j) < \rho(a_0)$ *for* $j = 1, \dots, n-2$, *if* $\rho(a_0) > 0$, *while* $a_1, \dots, a_{n-2}$ *are polynomials, if* $\rho(a_0) = 0$. *Then, given two linearly independent solutions* f_1, f_2 *of* (2.3.23), *we have that the quotient* f_1/f_2 *is of infinite order.*

A natural question is now whether somewhat similar results could be obtained, provided the dominant coefficient is some of the $a_1, \dots, a_{n-2}$ instead of a_0. Most important results of this type are due to Langley [115] and to Hellerstein, Miles and Rossi [72]. We first give a growth result from [72]:

THEOREM 2.3.14. *Considering linear differential equation* (2.3.22), *suppose that for some* k, $0 \leqslant k \leqslant n-1$, $\rho(a_j) < \rho(a_k) \leqslant 1/2$ *for all* $j \neq k$. *Then every solution of* (2.3.22) *is either a polynomial or an entire function of infinite order.*

Concerning zero distribution of a solution base of the reduced equation (2.3.23), corresponding to Theorem 2.2.1(a), we have the following result, see [115]:

THEOREM 2.3.15. *In the higher order case* $n \geqslant 3$, *suppose that all coefficients* a_j, $j = 0, \dots, n-2$, *of* (2.3.23) *are of order* $\rho(a_j) < \frac{1}{2(n-1)}$. *Then the linear differential* *equation* (2.3.23) *cannot have linearly independent solution* $f_1, \dots, f_n$ *each satisfying* $\lambda(f_j) < \infty$.

For additional results of similar type, see [111].

2.4. *Homogeneous linear differential equations with meromorphic coefficients*

If a linear differential equation (2.3.22) has meromorphic coefficients $a_j(z)$, $j = 1, \dots, n-1$, of which at least one is non-entire, then the existence of a meromorphic solution, resp. of a meromorphic solution base, in the whole complex plane becomes the first problem to be treated. Indeed, algebraic and logarithmic branch points may appear for such linear differential equations more as a rule than as an exception. As a simple classical example, consider a linear differential equations of type

$$f'' + \frac{h(z)}{(z - z_0)^2} f = 0$$

with $h(z)$ analytic in an open disc $B(z_0, R)$. Supposing that the indicial equation

$$\rho(\rho - 1) + h(z_0) = 0$$

has its roots ρ_1, ρ_2 such that $\rho_1 - \rho_2$ is a non-zero integer, then the equation admits two linearly independent solutions

$$f_1(z) = (z - z_0)^{\rho_1} \sum_{j=0}^{\infty} a_j (z - z_0)^j, \quad a_0 \neq 0,$$

$$f_2(z) = k f_1(z) \log(z - z_0) + (z - z_0)^{\rho_2} \sum_{j=0}^{\infty} b_j (z - z_0)^j,$$

where $k = 0$ or $k = 1$, in some slit disc $D := B(z_0, r) \setminus \{z_0 + t; 0 \leqslant t < r\}$, $r \leqslant R$. On the other hand, any meromorphic function f may appear as a global solution by just defining $A(z) := -f''(z)/f(z)$. Therefore, restricting ourselves to the most simple case of (2.1.1) with a meromorphic coefficient $A(z)$, a natural problem is to ask, when Eq. (2.1.1) admits two linearly independent meromorphic solutions in the whole complex plane, i.e. to characterizing when all solutions of (2.1.1) are globally meromorphic. To this end, the following result may be found, see [107], pp. 120–124:

THEOREM 2.4.1. *A linear differential equation* (2.1.1) *with* $A(z)$ *meromorphic in the complex plane admits two meromorphic solutions in the complex plane if and only if at all poles* z_0 *of* $A(z)$, *the Laurent expansion of* $A(z)$ *at* z_0 *is of the form*

$$A(z) = \frac{b_0}{(z - z_0)^2} + \frac{b_1}{z - z_0} + b_2 + \cdots,$$

where

$$4b_0 = 1 - m^2$$

for an odd integer $m \geqslant 3$, *and where the determinant*

$$D(z_0) = \begin{vmatrix} 1-m & 0 & \cdots & 0 & b_1 \\ b_1 & 4-2m & & & b_2 \\ b_2 & b_1 & \ddots & (0) & b_3 \\ \vdots & \vdots & & & \vdots \\ b_{m-2} & b_{m-3} & \cdots & (m-1)^2-(m-1)m & b_{m-1} \\ b_{m-1} & b_{m-2} & \cdots & b_1 & b_m \end{vmatrix} \tag{2.4.25}$$

vanishes.

In such a situation, when all solutions are meromorphic in the plane, a number of results are known to describe the distribution of zeros and poles of solutions, see [17]. It remains mostly open, however, to express these results in terms of the coefficient $A(z)$ only. To give a simple example, let f_1, f_2 be a meromorphic solution base. Then it is easy to see, from $(f_2/f_1)' = 1/f_1^2$, that all solutions have the same order of growth. On the other hand, contrary to the case of $A(z)$ entire, it may happen that all solutions are of finite order. A simple example may be provided by $f'' - (2/\cos^2 z)f = 0$ with $f_1(z) = \tan z$, $f_2(z) = 1 + z\tan z$. However, it remains open to characterize, in terms of $A(z)$ only, when the solutions are of finite order. Similarly, it is not known, in terms of $A(z)$ again, for which $A(z)$, there exist two linearly independent solutions f_1, f_2, each being zero-free in the whole complex plane.

Concerning the case when all solutions of (2.1.1) with a meromorphic coefficient $A(z)$ are of finite order, we may look at the Lamé equation

$$f'' - \big(q(q+1)\wp(z) + B\big)f = 0, \tag{2.4.26}$$

where $\wp(z)$ is the Weierstraß $\wp$-function, q a natural number and B a complex constant. In this case of (2.4.26), all solutions are meromorphic and if non-trivial, they are of order $\rho(f) = 2$. Moreover, we have $\lambda(f - a) = 2$ for all $a \in \mathbb{C}$, see [157], pp. 594–595. More generally, the same conclusions hold for all non-trivial solutions of (2.1.1), provided the coefficient $A(z)$ is a doubly periodic meromorphic function such that its Laurent expansion $A(z) = (z - z_0)^2 \sum_{j=0}^{\infty} b_j (z - z_0)^j$ satisfies around every pole z_0 of $A(z)$ the following conditions:

(1) $b_0 = -q(z_0)(q(z_0) + 1)$ for an integer $q(z_0)$,

$$(2)\ D(a) = \begin{vmatrix} \mu_1 & 0 & \cdots & & 0 & b_1 \\ b_1 & \mu_2 & \ddots & (0) & \vdots & b_2 \\ b_2 & b_1 & \ddots & \ddots & \vdots & b_3 \\ \vdots & \vdots & \ddots & \ddots & 0 & \vdots \\ b_{2q(a)-1} & b_{2q(a)-2} & \cdots & b_1 & \mu_{2q(a)} & b_{2q(a)} \\ b_{2q(a)} & b_{2q(a)-1} & \cdots & b_2 & b_1 & b_{2q(a)+1} \end{vmatrix} = 0,$$

where $\mu_j = j^2 - (2q(z_0)+1)j$, $1 \leqslant j \leqslant 2q(z_0)$. This more general case may be regarded as a generalized Lamé equation.

In the case, when the coefficient $A(z)$ in (2.1.1) is periodic of period ω, but not doubly periodic, and all solutions are supposed to be meromorphic, we may apply, under mild conditions, the Floquet theory to conclude that there exists a solution base, the members of which are of the type $f_j(z) = R_j(z)\exp(\beta_j z)$, where β_j is a complex constant, and $R_j(z)$ is rational in $\exp(2\pi i z/\omega)$, see [187]. For a number of results in the periodic case, see [160].

For a few examples of results describing the distribution of zeros and poles of meromorphic solutions in terms of $A(z)$ only, see [17]:

THEOREM 2.4.2. *Let $A(z)$ be a transcendental meromorphic function of order ρ such that all solutions of* (2.1.1) *are meromorphic in the complex plane. Then we have*

(a) *If $0 < \rho < \infty$, and if f_1, f_2 are linearly independent, then*

$$\max\bigl(\bar{\lambda}(f_1), \bar{\lambda}(f_2), \lambda(1/f_1)\bigr) \geqslant \rho.$$

(b) *If $\rho = 0$, then at least one of the following three sets is an infinite set of points: the zero-set of f_1, the zero-set of f_2, the pole-set of f_1.*

(c) *If $\rho > 0$ and if $\bar{\lambda}(A) < \rho$, then $\max(\bar{\lambda}(f), \bar{\lambda}(1/f)) \geqslant \rho$ for all non-trivial solutions f.*

(d) *If $\bar{\lambda}(f_1) < \infty$ and $\bar{\lambda}(f_2) < \infty$ for two linearly independent solutions f_1, f_2, then $\max(\bar{\lambda}(f), \bar{\lambda}(1/f)) = \infty$, unless all solutions are of finite order.*

Observe that these assertions represent a meromorphic counterpart of Theorem 2.2.1.

Of course, more refined information about the zeros of solutions of (2.3.22) follow if one is restricting the subset of $\mathbb{C}$ to be considered. An interesting paper of this type is due to Y. Il'yashenko and S. Yakovenko [89]. They consider a finite interval in $K \subset \mathbb{R}$, and its sufficiently small neighborhood U such that the coefficients $a_j(z)$ of (2.3.22) are analytic in U. Provided $|a_j(z)| \leqslant A$ in U for all $j = 0, \ldots, n-1$, then all non-trivial solutions that are real on K have at most $\beta(A+n)$ distinct zeros on K, where the constant β depends on the geometry of the pair (K, U) only. A more general result, removing the assumption that a solutions is real on K, was due to D. Novikov and S. Yakovenko in [138]:

THEOREM 2.4.3. *Let $K \subset U$ be a compact set in an open set $U \subset \mathbb{C}$ and suppose that K, U both have simply connected interiors and piecewise smooth boundaries. More-*

over, suppose that K *equals to the closure of its interior. Then all non-trivial solutions* f *of* (2.3.22) *with coefficients analytic in a neighborhood of* $\bar{U}$ *have at most* $\beta(A + n\log n)$ *distinct zeros in* K, *where now* $A := \max_{j=0,\dots,n-1}\max_{z\in U}|a_j(z)|$.

For a number of related generalizations, see [138].

2.5. *Non-homogeneous linear differential equations*

In this section, we describe key results concerning the growth and oscillation of solutions of non-homogeneous linear differential equations

$$f^{(n)} + a_{n-1}(z)f^{(n-1)} + \cdots + a_0(z)f = H(z) \tag{2.5.27}$$

with entire coefficients. It is well-known that all solutions of (2.5.27) are entire functions, see [107], Proposition 8.1. A typical phenomenon here is that the growth of solutions is essentially determined by the coefficients in the homogeneous part of (2.5.27), provided the finiteness degree of growth of $H(z)$ satisfies that $i(H) \leqslant 1 + \max_{j=0,\dots,n-1} i(a_j)$. As for the situation, when the coefficients $a_j(z)$, $j = 0, \dots, n-1$ are polynomials, while $H(z)$ is of finite order of growth, see two papers [55,57] by Gundersen, Steinbart and Wang. In what follows, we partially apply the same notations (2.1.12)–(2.1.15) as used with respect to the corresponding homogeneous equation (2.1.10) above. While looking at the results below, it also makes sense to compare with the corresponding results related to the homogeneous case (2.1.10) with polynomial coefficients. Recall that all solutions of the corresponding homogeneous linear differential equation are of growth

$$\rho(f) \leqslant \lambda := 1 + \max_{0\leqslant j\leqslant n-1} \frac{d_j}{n-j}$$

at most, while there always exist solutions of growth

$$\rho(f) = 1 + \max_{0\leqslant j\leqslant n-1} \frac{d_j}{n-j} = \alpha_1.$$

In the present non-homogeneous situation, elementary order considerations show that we always have $\rho(f) \geqslant \rho(H)$ for all solutions of (2.5.27). More precisely, we obtain

THEOREM 2.5.1. *All solutions* f *of* (2.5.27) *satisfy either* $\rho(f) = \rho(H)$, *or* $\rho(f) = \alpha_j$ *for some* $1 \leqslant j \leqslant p$, *provided* $\alpha_j > \rho(H)$, *and there always exists a solution* f *such that* $\rho(f) = \max(\rho(H), 1 + \alpha_1)$. *Moreover, if* $\rho(H)$ *is an integer, and if* $\rho(f) > \rho(H)$, *then* $\rho(f) \geqslant \rho(H) + 1/n$.

The last inequality here is sharp as shown by Example 4.1 in [57], and the assumption that $\rho(H)$ is an integer cannot be deleted, see Example 4.2 in [57].

Perhaps more interesting than the growth only is to see the influence of the non-homogeneity part H to the zero-distribution of f:

THEOREM 2.5.2. *For all solutions f of* (2.5.27), *we have*

$$\rho(f) - \lambda(f) \leqslant \rho(H) - \lambda(H).$$

Therefore, we always have $\lambda(f) \geqslant \lambda(H)$ and $\lambda(f) = \rho(f)$ as soon as $\lambda(H) = \rho(H)$.

THEOREM 2.5.3. *If $\lambda(H)$ is an integer, and if f is a solution of* (2.5.27) *such that $\lambda(f) > \lambda(H)$, then*

$$\lambda(f) \geqslant \lambda(H) + 1/n. \tag{2.5.28}$$

Again, observe that the inequality (2.5.28) is sharp, and the assumption that $\lambda(H)$ is an integer cannot be deleted, see examples in [57].

THEOREM 2.5.4. *If $\lambda(H) < \rho(H)$, and if f is a solution of* (2.5.27) *such that $\lambda(f) < \rho(f)$, then*

$$\rho(f) - \lambda(f) \geqslant \min\bigl(1/n, \rho(H) - \lambda(H)\bigr). \tag{2.5.29}$$

In particular, if $\rho(H) - \lambda(H) \leqslant 1/n$, and $\lambda(f) < \rho(f)$, then

$$\rho(f) - \lambda(f) = \rho(H) - \lambda(H). \tag{2.5.30}$$

Examples in [57] again show the sharpness of Theorem 2.5.4.

To obtain a counterpart of Theorem 2.1.7 in the non-homogeneous case (2.5.27), where $\lambda(H) < \rho(H) < \infty$, we need to write $H(z) = h(z)\mathrm{e}^{Q(z)}$, where $Q(z) = \frac{1}{\beta} b z^{\beta} + \cdots$ is a polynomial of degree β and h is an entire function such that $\lambda(h) = \rho(h) < \beta$. Let next A_j be the leading coefficient of $a_j(z) = A_j z^{d_j}$ in (2.5.27), and set $a_n(z) \equiv 1$. Setting then

$$\tau := \max_{0 \leqslant j \leqslant n} \bigl\{ d_j + j(\beta - 1) \bigr\},$$

we may define the constants $A_j^{\star}$ for $j = 0, \ldots, n$ as

$$A_j^{\star} := \begin{cases} A_k & \text{if } d_j + j(\beta - 1) = \tau, \\ 0 & \text{otherwise} \end{cases} \tag{2.5.31}$$

and a polynomial $H^{\star}(t)$ as

$$H^{\star}(t) := \sum_{j=0}^{n} A_j^{\star} t^j.$$

Using these notations, we obtain the following conclusions, see [55]:

THEOREM 2.5.5. *If b is a zero of multiplicity $m \geqslant 0$ of the polynomial $H^{\star}(t)$. Then Eq.* (2.5.27) *admits at most $m + 1$ linearly independent solutions f such that $\lambda(f) < \rho(f)$.*

In particular, each solution f *of* (2.5.27) *satisfies* $\lambda(f) < \rho(f)$ *if and only if* $H^{\star}(t) = (t-b)^n$.

Observe that this theorem also covers the case, when $H^{\star}(b) \neq 0$ showing that in this case their is at most one solution f such that $\lambda(f) < \rho(f)$.

THEOREM 2.5.6. *If the non-homogeneity part* H *in Eq.* (2.5.27) *is of infinite order, then all solutions* f *of* (2.5.27) *satisfy* $\lambda(f) = \rho(f) = \infty$ *with at most one exceptional solution* f_0.

Returning back to the finite vs. global oscillation properties treated above in the case of homogeneous linear differential equations (2.1.10) with polynomial coefficients, the corresponding behavior in the non-homogeneous case appears to be more complicated, see [7], Theorem 1.1:

THEOREM 2.5.7. *Suppose that all coefficients in Eq.* (2.5.27) *are polynomials with* $H(z) \not\equiv 0$. *Then there exist finitely many real numbers* s_j, $j = 1, \dots, m+1$, *with* $0 = s_0 < s_1 < \cdots < s_m < s_{m+1} = 2\pi$ *such that for each* k, $0 \leqslant k \leqslant m$, *one of the following properties hold*: (1) *for any* $\theta \in (s_k, s_{k+1})$ *and for any* $\varepsilon > 0$, *there is a solution of* (2.5.27) *having infinitely many zeros in* $|\arg z - \theta| < \varepsilon$ *or* (2) *for any* $\varepsilon > 0$, *any solution of* (2.5.27) *admits at most finitely many solutions in the sector* $s_k + \varepsilon \leqslant \arg z \leqslant s_{k+1} - \varepsilon$.

Therefore, in the non-homogeneous case, Eq. (2.5.27) has either the finite oscillation property, the global oscillation property, or a mixture of these two properties. An example of the last situation is

$$f''' + (z^2+3)f'' + (2z^2+z+3)f' + (z^2+z+2)f = H(z),$$

which has the global oscillation property in the left half plane, while four rays $\theta = -\pi/2, -\pi/6, \pi/6, \pi/2$ determine the finite oscillation property of this equation in the right half plane, see [7], pp. 290–291, for details.

We finally remark that there are very few results concerning the growth and zero distribution of solutions of (2.5.27), with coefficients being entire functions so that at least one of the coefficients in the homogeneous part is transcendental. We restrict ourselves here to giving just a couple of typical results, see [27] and [49]:

THEOREM 2.5.8. *Suppose that the coefficients in* (2.5.27) *are entire functions of finite order so that* $\rho(a_j) < \rho(a_0)$, $j = 1, \dots, n-1$. *Then all solutions* f *of* (2.5.27) *satisfy* $\bar{\lambda}(f) = \lambda(f) = \rho(f) = \infty$ *with at most one exceptional solution* f_0 *of finite order. If such an exceptional solution* f_0 *exists, then* $\rho(f_0) \leqslant \max\{\rho(a_0), \rho(H), \bar{\lambda}(f_0)\} < \infty$.

THEOREM 2.5.9. *Suppose that the coefficients in* (2.5.27) *are entire functions of finite order so that at least one of* $a_j(z)$, $j = 0, \dots, n-1$ *is transcendental. Then at least one of the solutions of* (2.5.27) *satisfies* $\bar{\lambda}(f) = \lambda(f) = \rho(f) = \infty$.

See also [24] for a result concerning the iterated order of solutions.

3. Linear differential equations in the unit disc

Meromorphic solutions of linear differential equations in the unit disc behave to some extent similarly as to the case of the complex plane, provided the solutions are fast growing in the sense of the Nevanlinna theory, i.e. that $T(r, f)/\log(1/(1-r))$ is unbounded. This case will be considered in Section 3.4. The complementary case of slowly growing solutions, which becomes trivial in the plane case, needs extensive consideration in the unit disc. In fact, analytic functions in the unit disc typically appear to be of slow growth when they belong to certain complex function spaces such as Hardy spaces, Bloch space, Q_p-spaces for some p etc. This gives rise to the general problem of investigating connections between the function spaces where the solutions, resp. the coefficients belong to. This topic has attracted systematic studies only very recently. Quite likely, new observations and improvements to the presentation in this chapter are to be expected in the near future. Another key aspect in investigating linear differential equations in the unit disc is the distribution of zeros of solutions. Historically, this topic preceded growth considerations, and combining these classical results on zero distribution with the recent growth studies is an open task of research today.

3.1. *Classical results on zeros of solutions*

Certain results about the zeros of solutions of linear differential equations in a disc of the complex plane are classical, although perhaps not so well-known, see [76]. To give an example of such classical theorems, consider the linear differential equation

$$f'' + A(z)f = 0, \tag{3.1.1}$$

where $A(z)$ is analytic:

THEOREM 3.1.1. (See [76], p. 580.) *Suppose $A(z)$ is analytic in a disc $|z - z_0| < R$ and bounded there by $|A(z)| \leqslant M$. Let f be a solution of $f'' + A(z)f = 0$ in this disc. Then we have*:

(i) *If f satisfies the initial conditions $f(z_0) = 0$, $f'(z_0) = 1$, then f has no zeros in the punctured disc $0 < |z - z_0| < \min(R, \pi M^{-1/2})$.*

(ii) *If f satisfies the initial conditions $f(z_0) = 1$, $f'(z_0) = 0$, then f has no zeros in the disc $|z - z_0| < \min(R, \frac{1}{2}\pi M^{-1/2})$.*

This type of classical results, connected with the closely related problem of the univalence of solutions of (3.1.1) prompted quite a lot of activity in 1950's. Unfortunately, this activity gradually faded out, being perhaps again reviving. The basic notions to be considered in this connection are related to the oscillatory nature of solutions. For the sake of normalization, we shall consider the situation in the unit disc $\mathbb{D}$ only. Of course, by a simple rescaling, any finite disc in the complex plane could be treated as well.

The differential equation

$$f'' + A(z)f = 0, \tag{3.1.2}$$

where $A(z)$ is analytic in $\mathbb{D}$, is said to be *oscillatory*, if at least one of its non-trivial solutions has infinitely many zeros in the unit disc $\mathbb{D}$. Otherwise, Eq. (3.1.2) is called *non-oscillatory*. Two more notions applied in this connection are *disconjugate*, meaning that every non-trivial solution of (3.1.2) has at most one zero in $\mathbb{D}$, and *Blaschke-oscillatory* meaning that the zero sequence (z_j) of every non-trivial solution of (3.1.2) is a Blaschke sequence, i.e. that $\sum_{j=1}^{\infty}(1-|z_j|)$ converges.

The research activity in early 1950's was very much due to the short but important paper [132] by Nehari, see also [134,135]. In particular, he proved the following theorem, which connects the notion of univalence to solutions of (3.1.2) in the unit disc:

THEOREM 3.1.2. *Given two linearly independent solutions f_1, f_2 of Eq.* (3.1.2), *their quotient g takes a complex value α n times in $\mathbb{D}$ if and only if there exists a non-trivial solutions of* (3.1.2) *that has n zeros in $\mathbb{D}$. In particular, g is univalent if and only if Eq.* (3.1.2) *is disconjugate.*

Actually, the proof of this theorem is quite elementary: If $g = f_1/f_2$ takes a certain value $\alpha \in \mathbb{C}$ at some point z, then $f_1 - \alpha f_2$ vanishes at z.

Making use of Theorem 3.1.2, Nehari [132] proved the following non-oscillation theorem:

THEOREM 3.1.3. *If*

$$\left|A(z)\right| \leqslant \frac{1}{(1-|z|^2)^2}$$

in the unit disc $\mathbb{D}$, then Eq. (3.1.2) *is disconjugate.*

The same conclusion holds, if $|A(z)| \leqslant \frac{2}{1-|z|^2}$, see Pokornyi [142]. Observe that Theorem 3.1.3 is in some sense close to the best possible, as shown by Schwarz [152]:

THEOREM 3.1.4. *If the inequality in Theorem* 3.1.3 *holds close to the boundary of $\mathbb{D}$, i.e. in $r_0 \leqslant |z| < 1$ for some $r_0 > 0$, then equation* (3.1.2) *is non-oscillatory. Moreover, for each $\gamma > 0$, there exists $A(z)$ such that*

$$|A(z)| \leqslant \frac{1+4\gamma^2}{(1-|z|^2)^2}$$

and that Eq. (3.1.2) *becomes oscillatory.*

For the proof of the first assertion, see [152], pp. 160–162. On the other hand, taking

$$A(z) = \frac{1+4\gamma^2}{(1-z^2)^2},$$

the corresponding Eq. (3.1.2) has an analytic solution

$$f(z) = (z^2 - 1)^{1/2} \sin\left(\gamma \log \frac{1+z}{1-z} - C\right)$$

in the unit disc, which has infinitely many zeros in $\mathbb{D}$, provided C is real (and provided that the branches of square root and logarithm have been chosen suitably).

A substantial number of oscillation results for (3.1.2) in the unit disc come out by integration of $|A(z)|$. Denoting by $\mathrm{d}\sigma$ the standard area element in the complex plane, the following conclusions may be found in [124]:

THEOREM 3.1.5. *Equation* (3.1.2) *is disconjugate, resp. non-oscillatory, if* $\int_{\mathbb{D}} |A(z)|\,\mathrm{d}\sigma \leqslant \pi$, *resp.* $< \infty$.

PROOF. The first assertion is an immediate consequence of Theorem 3.1.3, combined with the standard estimate

$$\pi\left(1 - |\zeta|^2\right)^2 \left|A(\zeta)\right| \leqslant \int_{\mathbb{D}} \left|A(z)\right| \mathrm{d}\sigma, \quad |\zeta| < 1$$

for analytic functions in the unit disc.

The second assertion essentially follows from the invariance of area integrals of analytic functions under Möbius transformations of the independent variable, see [124], pp. 982–986. □

A corresponding pair of oscillation results follows by computing the boundary integral of $|A(z)|$ instead of the area integral. Observing that $I(\rho, A) := \int_0^{2\pi} |A(\rho e^{i\theta})|\,\mathrm{d}\theta$ is nondecreasing, we may define

$$I(1, A) := \lim_{\rho \to 1} I(\rho, A).$$

A counterpart to Theorem 3.1.5 is now

THEOREM 3.1.6. *Equation* (3.1.2) *is disconjugate, resp. non-oscillatory, if* $I(1, A) \leqslant 4\pi$, *resp.* $I(1, A) < \infty$.

PROOF. The first assertion follows by combining the disconjugacy criterion due to Pokornyi, see the remark after Theorem 3.1.3, with the inequality

$$2\pi\left(1 - |\zeta|^2\right)\left|A(\zeta)\right| \leqslant I(1, A)$$

due to Nehari, see [133], p. 127. On the other hand, the second assertion is an immediate consequence of the corresponding non-oscillation criterion in Theorem 3.1.5. □

For additional, related results, see [34].

An immediate problem open for further investigations is the sharpness of the bounds in disconjugacy criteria π and 4π in Theorems 3.1.5 and 3.1.6, respectively. The example

$f'' + \frac{\pi^2}{4} f = 0$ due to London [124] shows that the bounds are definitely not sharp. Indeed, we have in this case $\int_{\mathbb{D}} |A(z)|\, d\sigma = \frac{\pi^3}{4} \approx 2.467\pi$ and $I(1, A) = \frac{\pi^3}{2} \approx 4.935\pi$. On the other hand, the boundary integral value is not too far from the best possible bound as shown by the following example due to Heittokangas [67]: Considering

$$f'' + \frac{10\zeta^2 - z^2}{4\zeta^4} f = 0, \quad |\zeta| < 1,$$

it is not difficult to see that this equation has a solution with two zeros at $\pm\zeta$, and so the equation is not disconjugate. On the other hand, by numerical computation, we see that the area integral $\int_{\mathbb{D}} |A(z)|\, d\sigma(z) \approx 5\pi/(2\zeta^2)$, while $I(1, A) \approx 5.013\pi$ as $|\zeta|$ is conveniently chosen close to one. Therefore, it is natural to conjecture that the possible constant might be $5\pi/2$ and 5π, respectively.

It is trivial to observe that disconjugate and non-oscillatory equations (3.1.2) are Blaschke-oscillatory. However, characterizing Blaschke-oscillatory equations (3.1.2) remains defectively investigated by now. The key results into this direction read as follows, see Pommerenke [143] and Heittokangas [65,66]:

THEOREM 3.1.7. *If* $A(z)$ *is analytic in* $\mathbb{D}$ *and either* $\int_{\mathbb{D}} |A(z)|^{1/2}\, d\sigma(z) < \infty$ *or* $\int_{\mathbb{D}} |A(z)|(1 - |z|)\, d\sigma(z) < \infty$, *then Eq.* (3.1.2) *is Blaschke-oscillatory.*

THEOREM 3.1.8. *If* $A(z)$ *is analytic in* $\mathbb{D}$ *and Eq.* (3.1.2) *is Blaschke-oscillatory, then* $\int_{\mathbb{D}} |A(z)|^{\alpha}\, d\sigma(z) < \infty$ *for each* $\alpha \in (0, 1/2)$.

The first of these results is an easy consequence of [143], Theorem 5, while the second one can be proved by using the unit disc version of the second main theorem of Nevanlinna theory, see [66], p. 126. Observe that the two integral conditions in Theorem 3.1.7 are independent of each other, as one may see by [70], Section 4. Also observe that there exist Blaschke-oscillatory equations of the form (3.1.2) for which neither one of the conditions in Theorem 3.1.7 is not satisfied, as one may easily see by looking at the equation

$$f'' - \frac{4}{(1 - z)^4} f = 0,$$

see [66], pp. 121–122. Concerning the next result, see [65], pp. 55–56:

THEOREM 3.1.9. *Suppose the coefficient* $A(z)$ *in* (3.1.2) *belongs to the Hardy space* H^p. *If* $1/4 \leqslant p \leqslant \infty$, *then* (3.1.2) *is Blaschke-oscillatory. Moreover, if* $1 \leqslant p \leqslant \infty$, *then* (3.1.2) *is non-oscillatory.*

This is sharp in the following sense: Eq. (3.1.2) with $A(z) := 4/(1 - z)^4$ is not Blaschke-oscillatory, while $A \in H^p$ for all $p < 1/4$, but $A \notin H^{1/4}$, see [65], p. 56.

A natural question about zeros of solutions of (3.1.2) is their geometric distribution inside of the unit disc. This problem has been addressed by Schwarz [152], Beesack [21] and Herold [75] by considering the hyperbolic non-Euclidean distance between zeros, while

Schwarz [152] and Beesack [20] also considered Euclidean distance between zeros. To describe these results, recall first that the hyperbolic non-Euclidean distance between two points z_1, z_2 in the unit disc will be defined as

$$[z_1, z_2] := \int_\gamma \frac{\mathrm{d}\zeta}{1-|\zeta|^2},$$

where the path of integration γ is the circle arc joining z_1 and z_2, orthogonal to the unit circle. Schwarz now proved the following theorem:

THEOREM 3.1.10. *Let f be a non-trivial solution of* (3.1.2).

(a) *If*

$$|A(z)| \leqslant \frac{1+a^2}{(1-|z|^2)^2}$$

for some $a > 0$ and if z_1, z_2 are two zeros of f in $\mathbb{D}$, then

$$[z_1, z_2] > \log \frac{\sqrt{1+a^2}+1}{\sqrt{1+a^2}-1}.$$

(b) *On the other hand, if for any two zeros z_1, z_2 in the unit disc $\mathbb{D}$,*

$$[z_1, z_2] \geqslant \log \frac{\sqrt{1+a^2}+1}{\sqrt{1+a^2}-1}, \quad a > 0,$$

then

$$|A(z)| < \frac{3(1+a^2)}{(1-|z|^2)^2}.$$

Herold [75] improved the first part of the preceding theorem by proving

THEOREM 3.1.11. *Let f be a non-trivial solution of* (3.1.2) *and suppose that*

$$|A(z)| \leqslant \frac{1+a^2}{(1-|z|^2)^2}.$$

Then for any two zeros z_1, z_2 of f in the unit disc $\mathbb{D}$,

$$[z_1, z_2] \geqslant \frac{\pi}{a}.$$

Theorem 3.1.11 is in fact best possible, as shown by the following example which goes back to Schwarz, see [152], p. 171, and [75], p. 638:

The function in the unit disc $\mathbb{D}$ defined as

$$f(z) := \sqrt{1-z^2}\sin\left(\frac{\alpha}{2}\log\frac{1+z}{1-z}\right),$$

where $\log 1 = 0$, is a solution of

$$f'' + \frac{1+\alpha^2}{(1-z^2)^2} f = 0.$$

The zeros z_n of f in the unit disc are determined by

$$\log\frac{1+z_n}{1-z_n} = n\frac{2\pi}{\alpha}, \quad n \in \mathbb{Z}.$$

By an elementary computation,

$$[z_n, z_{n+1}] = \int_{z_n}^{z_{n+1}} \frac{\mathrm{d}t}{1-t^2} = \Big/_{z_n}^{z_{n+1}} \frac{1}{2}\log\frac{1+t}{1-t} = \frac{\pi}{\alpha}.$$

3.2. *Complex function spaces in the unit disc*

Describing the growth and zero distribution of solutions of linear differential equations in the unit disc essentially relies on characterizing the coefficients of the equation as well as of its solutions in terms of complex functions spaces in the unit disc. Indeed, we may consider meromorphic functions f in the unit disc in two classes: Defining

$$D(f) := \limsup_{r\to 1^-} \frac{T(r,f)}{\log(1/(1-r))},$$

we say that f is of *finite degree*, if $D(f) < \infty$, while if $D(f) = \infty$, we say that f is of *infinite degree*. Of course, we may also say that f is of degree β, if $D(f) = \beta$. Observe that the finiteness of degree of f could also be defined for analytic functions as

$$D_M(f) := \limsup_{r\to 1^-} \frac{\log M(r,f)}{\log(1/(1-r))}$$

instead of $D(f)$. Clearly, $D(f) \leqslant D_M(f)$. However, $D_M(f)$ is not equivalent to $D(f)$ in defining the finiteness of degree, as shown by $f(z) := \mathrm{e}^{1/(1-z)}$. In this case, $D_M(f) = \infty$ and $D(f) < \infty$ by simple computation.

It is important to observe that the unit disc version of Nevanlinna theory remains a powerful tool while considering fast growing solutions of complex differential equations in the unit disc, meaning that the solution under consideration is of infinite degree and is growing essentially faster than the coefficients of the equation. On the other hand, solutions of slow growth need different tools, as in this situation the growth of a solution is comparable with the growth of coefficients. Due to recent studies, the theory of complex functions spaces takes the role of a key device to attack the situation.

For the convenience of the reader, we shortly recall basic definitions of the complex analytic spaces needed in what follows.

Perhaps the most classical linear space of analytic functions in the unit disc is the *Hardy space* H^p of analytic functions f satisfying the inequality

$$\sup_{0\leqslant r<1}\left(\frac{1}{2\pi}\int_0^{2\pi}\left|f(re^{i\theta})\right|^p d\theta\right)^{1/p}<\infty$$

for $0<p<\infty$, while for $p=\infty$, the corresponding Hardy space H^∞ is just the space of analytic functions bounded in the unit disc. For basic properties of Hardy spaces, see [36]. To define a natural extension of Hardy spaces H^p, $0<p<\infty$, we consider the p-characteristic of an analytic function f defined as

$$m_p(r,f):=\left(\frac{1}{2\pi}\int_0^{2\pi}\left(\log^+\left|f(re^{i\theta})\right|\right)^p d\theta\right)^{1/p}\tag{3.2.3}$$

for $0\leqslant r<1$. Now, the *generalized Nevanlinna class* N^p consists of all analytic functions f in the unit disc for which $\sup_{0\leqslant r<1}m_p(r,f)<\infty$. Observe that N^p is actually a linear space, and for each p, $\bigcup_0^\infty H^p\subset N^p$. The classical Nevanlinna class then is nothing but $N:=N^1$.

We next define the *weighted Hardy spaces* H_q^p, resp. H_q^∞ for $0\leqslant q<\infty$ as analytic functions f in the unit disc satisfying

$$\sup_{0\leqslant r<1}(1-r^2)^q\left(\frac{1}{2\pi}\int_0^{2\pi}\left|f(re^{i\theta})\right|^p d\theta\right)^{1/p}<\infty,$$

resp.

$$\sup_{z\in\mathbb{D}}\left(1-|z|^2\right)^q\left|f(z)\right|<\infty.$$

Clearly, $H^p=H_0^p$ and $H^\infty=H_0^\infty$. Finally, we say that an analytic function $f\in H_{q,0}^\infty$, if

$$\lim_{|z|\to1^-}\left(1-|z|^2\right)^q\left|f(z)\right|=0,$$

and correspondingly for $f\in H_{q,0}^p$. A closely related analytic function space is the *Korenblum space*

$$\mathcal{H}:=\bigcup_{q\in[0,\infty)}H_q^\infty.$$

In some sense, Bergman, resp. weighted Bergman, spaces may be understood as the area integral counterparts of Hardy spaces. Given $0<p<\infty$ and $-1<\alpha<\infty$, the *weighted*

Bergman space A^p_α is defined as the family of analytic functions f in the unit disc $\mathbb{D}$ for which the area integral over the unit disc satisfies

$$\left(\int_{\mathbb{D}} \left|f(z)\right|^p \left(1-|z|^2\right)^\alpha \,\mathrm{d}\sigma\right)^{1/p} < \infty.$$

For $\alpha = 0$, we obtain the classical *Bergman space* A^p. Observe that $A^p \subset H^\infty_{2/p}$ and $H^\infty_p \subset A^{\varepsilon/p}$ for each $\varepsilon \in (0,1)$, see [64], p. 11.

Applying the derivative of an analytic function f in the unit disc, a collection of further complex function spaces follow. The classical starting point in this direction is the space $\mathcal{B}$ of *Bloch functions* defined as those functions satisfying

$$\sup_{z\in\mathbb{D}} \left(1-|z|^2\right)\left|f'(z)\right| < \infty.$$

Slightly more generally, we may consider the *α-Bloch space* $\mathcal{B}^\alpha$ defined by

$$\sup_{z\in\mathbb{D}} \left(1-|z|^2\right)^\alpha \left|f'(z)\right| < \infty$$

for $0 < \alpha < \infty$. A connection to weighted Hardy spaces appears by the equality $\mathcal{B}^\alpha = H^\infty_{\alpha-1}$ for $1 < \alpha < \infty$, see [196], Proposition 7.

There are now two standard types of corresponding area integral counterparts of Bloch spaces. The more classical of them is the notion of *Dirichlet spaces*, resp. *weighted Dirichlet spaces*. For $-1 < q < \infty$, an analytic function f in the unit disc is said to be in the weighted Dirichlet space $\mathcal{D}_q$, provided

$$\int_{\mathbb{D}} \left|f'(z)\right|^2 \left(1-|z|^2\right)^q \,\mathrm{d}\sigma < \infty.$$

Of course, $\mathcal{D} := D_0$ is the classical Dirichlet space.

We also need related notion of Dirichlet type spaces $\mathcal{D}^p$ consisting of analytic functions f in the unit disc such that

$$\int_{\mathbb{D}} \left|f'(z)\right|^p \left(1-|z|^2\right)^{p-1} \,\mathrm{d}\sigma < \infty.$$

Of course, this means that $f' \in A^p_{p-1}$.

More recent is the notion of Q_p-spaces, introduced by Aulaskari and Lappan [1] in 1994. These spaces are defined for $0 < p < \infty$ as analytic functions f in the unit disc that satisfy

$$\sup_{a\in\mathbb{D}} \int_{\mathbb{D}} \left|f'(z)\right|^2 \left(g(z,a)\right)^p \,\mathrm{d}\sigma(z) < \infty,$$

where $g(z,a) = \log((1-\bar{a}z)/(z-a))$ is the usual Green function of the unit disc with a logarithmic singularity at $a \in \mathbb{D}$. As shown by Aulaskari and Lappan in [1], Q_p equals to the Bloch space $\mathcal{B}$, provided $p > 1$. Moreover, $Q_1 = BMOA$, where *BMOA* is the space of analytic functions of *bounded mean oscillation*. It is also important to keep in mind the strict nesting property $Q_p \subset Q_q \subset BMOA \subset \mathcal{B}$ whenever $0 < p < q < 1$.

Finally, replacing the derivative with the spherical derivative, we obtain the definition of *α-normal functions* instead of *α-Bloch functions*: A meromorphic function f in the unit disc is said to belong to the class of *α-normal functions* $\mathcal{N}^\alpha$, provided

$$\sup_{z\in\mathbb{D}}\bigl(1-|z|^2\bigr)^\alpha f^\sharp(z) < \infty.$$

Of course, $\mathcal{N}^1$ is nothing but the classical class $\mathcal{N}$ of *normal meromorphic functions* in the unit disc. Finally, we say that f is strongly normal, if

$$\lim_{|z|\to 1^-}\bigl(1-|z|^2\bigr) f^\sharp(z) = 0.$$

3.3. *Growth estimates for homogeneous linear differential equations*

In this section, we recall some recent results, which have appeared to be extremely powerful while considering the growth of solutions of homogeneous linear differential equations

$$L(f) := f^{(n)} + a_{n-1}(z) f^{(n-1)} + \cdots + a_0(z) f = 0 \tag{3.3.4}$$

in the unit disc, with analytic coefficients. The first two results [68] below make use of the classical Gronwall lemma to obtain a growth estimate for solutions of (3.3.4). Surprisingly, these estimates are, qualitatively, best possible.

THEOREM 3.3.1. *Let f be a solution of* (3.3.4) *in a disc D_R of radius R, centered at the origin.*

(a) *If $0 < R \leqslant 1$, then there exist a constant $C_1 = C_1(k) > 0$, depending on the initial conditions at the origin, and a constant $C_2 = C_2(k) > 0$, such that*

$$\bigl|f(r\mathrm{e}^{\mathrm{i}\theta})\bigr| \leqslant C_1 \exp\left(C_2 \sum_{j=0}^{n-1}\sum_{k=0}^{j}\int_0^r \bigl|a_j^{(k)}(s\mathrm{e}^{\mathrm{i}\theta})\bigr|(R-s)^{n-j+k-1}\,\mathrm{d}s\right) \tag{3.3.5}$$

for all $\theta \in [0, 2\pi)$ and $r \in [0, R)$.

(b) *If $1 < R \leqslant \infty$, then there exist a constant $C_1 = C_1(k) > 0$, depending on the initial conditions at the origin, and a constant $C_2 = C_2(k) > 0$, such that*

$$\bigl|f(r\mathrm{e}^{\mathrm{i}\theta})\bigr| \leqslant C_1 r^{n-1} \exp\left(C_2 \sum_{j=0}^{n-1}\sum_{k=0}^{j}\int_0^r \bigl|a_j^{(k)}(s\mathrm{e}^{\mathrm{i}\theta})\bigr| s^{n-j+k-1}\,\mathrm{d}s\right) \tag{3.3.6}$$

for all $\theta \in [0, 2\pi)$ and $r \in (1, R)$.

Combining the p-characteristic of an analytic function with the preceding theorem it is a straightforward conclusion to obtain

COROLLARY 3.3.2. *Let f be a solution of* (3.3.4) *in a disc D_R of radius R, centered at the origin, and let $1 \leqslant p < \infty$ be given.*

(a) *If $0 < R \leqslant 1$, then there exist a constant $C_1 = C_1(k) > 0$, depending on the initial conditions at the origin, and a constant $C_2 = C_2(k) > 0$, both depending on p, such that*

$$m_p(r, f)^p \leqslant C_1 + C_2 \sum_{j=0}^{n-1} \sum_{k=0}^{j} \int_0^{2\pi} \int_0^r \left|a_j^{(k)}(s\mathrm{e}^{\mathrm{i}\theta})\right|(R-s)^{p(n-j+k-1)}\,\mathrm{d}s\,\mathrm{d}\theta \tag{3.3.7}$$

for all $r \in [0, R)$.

(b) *If $1 < R \leqslant \infty$, then there exist a constant $C_1 = C_1(k) > 0$, depending on f, and a constant $C_2 = C_2(k) > 0$, both depending on p, such that*

$$m_p(r, f)^p \leqslant C_1(\log r^{n-1})^p + C_2 \sum_{j=0}^{n-1} \sum_{k=0}^{j} \int_0^{2\pi} \int_0^r \left|a_j^{(k)}(s\mathrm{e}^{\mathrm{i}\theta})\right| s^{p(n-j+k-1)}\,\mathrm{d}s\,\mathrm{d}\theta \tag{3.3.8}$$

for all $r \in (1, R)$.

REMARK. Of course, the right-hand side integrals in (3.3.7) and (3.3.8) may be replaced by area integrals over the disc of radius r, if needed. The same remark also applies to (3.3.10).

Closely related estimates follow by applying a slight variant, see [68], of a comparison theorem due to Herold ([73], Satz 1):

THEOREM 3.3.3. *Let f be a solution of* (3.3.4) *in a disc D_R of radius R, where $0 < R \leqslant \infty$, centered at the origin, let b be the number of non-zero elements in the coefficient sequence $a_0, \dots, a_{n-1}$. Given $\theta \in [0, 2\pi)$ and $\varepsilon > 0$, if $z_\theta = \sigma \mathrm{e}^{\mathrm{i}\theta} \in D_R$ is such that $a_j(z_\theta) \neq 0$ for some of the coefficients, then we have for all r such that $\sigma < r < R$,*

$$\left|f(r\mathrm{e}^{\mathrm{i}\theta})\right| \leqslant C \exp\left(b \int_\sigma^r \max_{0 \leqslant j \leqslant n-1} \left|a_j(t\mathrm{e}^{\mathrm{i}\theta})\right|^{1/(n-j)}\,\mathrm{d}t\right), \tag{3.3.9}$$

where $C > 0$ is a constant depending on b and $a_j(z_\theta)$, $f^{(j)}(z_\theta)$, $j = 0, \dots, n-1$. Actually,

$$C \leqslant (1+\varepsilon) \max_{j=0,\dots,n-1} \left(\frac{|f^{(j)}(z_\theta)|}{b^j \max_{k=0,\dots,n-1} |a_k(z_\theta)|^{j(n-k)}} \right).$$

Similarly as in the Gronwall estimate case, the following corollary is an easy consequence:

COROLLARY 3.3.4. *Let f be a solution of* (3.3.4) *in a disc D_R of radius R, where $0 < R \leqslant \infty$, centered at the origin, and let $1 \leqslant p < \infty$. Then, for all $0 \leqslant r < R$, we have*

$$m_p(r, f)^p \leqslant C\left(1 + \sum_{j=0}^{n-1} \int_0^{2\pi}\int_0^r \left|a_j(se^{i\theta})\right|^{p/(n-j)} \,\mathrm{d}s\,\mathrm{d}\theta\right), \tag{3.3.10}$$

where $C = C(n) > 0$ is a constant depending on p, and on the initial values of f at a point z_θ, where at least one of the coefficients a_j takes a non-zero value.

We also recall certain pointwise estimates for the generalized meromorphic functions in the unit disc, corresponding to similar estimates due to Gundersen in the plane. For a more detailed exposition, see [33]. The first estimate here, see [69], Lemma B, is a variant of the original version in [33]:

THEOREM 3.3.5. *Given two integers k, j such that $k > j \geqslant 0$, $\varepsilon > 0$ and $\beta \in (0,1)$, if f is meromorphic in the unit disc $\mathbb{D}$ and $f^{(j)}$ does not vanish identically, then for all z such that $r = |z| \notin E$, where E is of finite logarithmic measure, i.e. $\int_E (1-r)^{-1}\,\mathrm{d}r < \infty$, we have*

$$\left|\frac{f^{(k)}(z)}{f^{(j)}(z)}\right| \leqslant \left(\left(\frac{1}{1-r}\right)^{2+\varepsilon} \max\left(\log\frac{1}{1-r}, T\big(s(r), f\big)\right)\right)^{n-j}, \tag{3.3.11}$$

where $s(r) := 1 - \beta(1-r)$. If f is of finite order $\rho(f)$ in the unit disc, then

$$\left|\frac{f^{(k)}(z)}{f^{(j)}(z)}\right| \leqslant \left(\frac{1}{1-r}\right)^{(n-j)(\rho(f)+2+\varepsilon)}, \quad r \notin E, \tag{3.3.12}$$

while if f is of finite iterated order $\rho_k(f)$ for some $k \geqslant 2$, then

$$\left|\frac{f^{(k)}(z)}{f^{(j)}(z)}\right| \leqslant \exp_{k-1}\left(\left(\frac{1}{1-r}\right)^{\rho(f)+\varepsilon}\right), \quad r \notin E. \tag{3.3.13}$$

Finally, we mention that the notion of disconjugacy treated relative to Eq. (3.1.1) above may be extended to the higher order case (3.3.4), see [116]: Equation (3.3.4) is said to be desconjugate in the unit disc $\mathbb{D}$, if all non-trivial solutions have at most $n-1$ zeros in $\mathbb{D}$. For disconjugacy results in this setting, see [58,101,116] and [117].

3.4. *Equations with fast growing solutions*

The key notion in these considerations, essentially started by Heittokangas in his thesis [64] in 2000, is the order, resp. iterated order, of an analytic, resp. meromorphic, function

f in the unit disc $\mathbb{D}$. Defining for analytic functions

$$\rho_j(f) := \limsup_{r\to 1^-} \frac{\log_j^+ T(r,f)}{-\log(1-r)}$$

and

$$\rho_{M,j}(f) := \limsup_{r\to 1^-} \frac{\log_{j+1}^+ M(r,f)}{-\log(1-r)},$$

it is immediate to observe that $\rho(f) \leqslant \rho_M(f) \leqslant \rho(f) + 1$ for the usual order, while $\rho_j(f) = \rho_{M,j}(f)$ for $j \geqslant 2$. Therefore, unless otherwise specified, we use $\rho_j(f)$ to describe the order in what follows in this section. A starting point for order considerations of solutions of homogeneous linear differential equations (3.3.4) in the unit disc with analytic coefficients is the following counterpart of the Frei theorem, Theorem 2.3.1, in the complex plane:

THEOREM 3.4.1. *Let a_j be the last coefficient in the sequence $a_0, \ldots, a_{n-1}$ not belonging to the Korenblum space $\mathcal{H}$. Then Eq.* (3.3.4) *possesses at most j linearly independent solutions of finite order of growth in $\mathbb{D}$.*

This theorem, due to Heittokangas, see [64], Theorem 6.3, has been recently generalized by using the notion of iterated order, see [25] and [69]. To this end, we introduce the unit disc counterpart of the *finiteness degree* $i(f)$ of f, and the related notions, see Section 2.3. So, $i(f) := 0$ for meromorphic functions of finite degree and $i(f) := \min\{s \in \mathbb{N};\ \rho_s(f) < \infty\}$ for meromorphic functions of infinite degree. Of course, this means that $i(f) = \infty$, if $\rho_s(f) = \infty$ for all $s \in \mathbb{N}$. Of course, we may use $\rho_M(f)$ as well, equivalently, to determine $i(f)$ for analytic functions in the unit disc. Exactly as in Section 2.3, we then define in this unit disc setting $\delta(L), \gamma_j(L), p(L)$ and $\kappa(L)$. Also, we may use $\gamma_{M,j}(L)$ and $\kappa_M(L)$, if needed, observing that $\gamma_\delta(L) = \gamma_{M,\delta}(L)$, if $\delta > 1$, and $\gamma_1(L) \leqslant \gamma_{M,1}(L) \leqslant \gamma_1(L) + 1$, if $\delta = 1$. Similarly, $\kappa(L) = \kappa_M(L)$, if $p(L) > 1$ and $\kappa(L) \leqslant \kappa_M(L) \leqslant \kappa(L) + 1$, if $p = 1$.

THEOREM 3.4.2. (See [25], Theorem 2.1.) *For Eq.* (3.3.4), *the following conditions always hold*:

(i) $\delta(L) \leqslant 1 + p(L)$,
(ii) *if* $1 < p < \infty$, *then* $\delta(L) = 1 + p(L)$ *and* $\kappa_M(L) = \gamma_{M,p+1}(L) = \gamma_{p+1} = \kappa(L)$,
(iii) *if* $p = 0$ *and* $m := \max_j D_M(a_j)$, *then* $\gamma_1(L) \leqslant \gamma_{M,1}(L) \leqslant 1 + m$.

There are a number of recent results, see [25,69] and [104], that are improvements of the preceding theorem:

THEOREM 3.4.3. (See [69], Theorem 1.1, [25], Theorem 2.2.) *Given $k \in \mathbb{N}$ and $\alpha \geqslant 0$, all solutions of* (3.3.4) *in $\mathbb{D}$ satisfy $\rho_{M,k+1}(f) \leqslant \alpha$ if and only if $\rho_{M,k}(a_j) \leqslant \alpha$ for all $j = 0, \ldots, n-1$. Moreover, if q, $0 \leqslant q \leqslant n-1$ is the largest index such that $\rho_{M,k}(a_q) =$*

$\max_{0\leqslant j\leqslant n-1}\rho_{M,k}(a_j)$, *then each solution base of* (3.3.4) *possesses at least* $n-q$ *linearly independent solutions* f *such that* $\rho_{M,k+1}(f)=\rho_{M,k}(a_q)$.

This result is sharp in the sense that examples exist of a solution base containing exactly $n-q$ solutions of maximal growth, see [69], Example 1.3. On the other hand, examples of (3.3.4) exist such that all non-trivial solutions are of maximal growth, see [69], Example 1.4.

THEOREM 3.4.4. (See [25], Theorem 2.3, [69], Theorem 1.2.) *Suppose* $0<p<\infty$ *and* $i(a_0)=p$. *If* $\max_{1\leqslant j\leqslant n-1} i(a_j)<p$ *or if* $\max_{1\leqslant j\leqslant n-1}\rho_{M,p}(a_j)<\rho_{M,p}(a_0)$, *then for all solutions* f *of* (3.3.4), $i(f)=p+1$ *and* $\rho_{M,p+1}(f)=\rho_{M,p}(a_0)$.

The preceding theorems may be slightly refined by introducing the notion of *iterated type*: Given $k\in\mathbb{N}$, and an analytic function f in the unit disc $\mathbb{D}$ such that $0<\rho_{M,k}(f)<\infty$, we define the iterated k-type as

$$\tau_{M,k}(f):=\limsup_{r\to 1^-}(1-r)^{\rho_{M,k}(f)}\log_k^+ M(r,f).$$

THEOREM 3.4.5. (See [69], Theorem 1.5.) *Given* $k\in\mathbb{N}$, *suppose that*

$$\max_{1\leqslant j\leqslant n-1}\rho_{M,k}(a_j)\leqslant\rho_{M,k}(a_0)$$

and that

$$\sum_{\rho_{M,k}(a_j)=\rho_{M,k}(a_0)}\tau_{M,k}(a_j)<\tau_{M,k}(a_0),$$

then all non-trivial solutions f *of* (3.3.4) *satisfy* $\rho_{M,k+1}(f)=\rho_{M,k}(a_0)$.

REMARK. Concerning Theorems 3.4.4 and 3.4.5, it remains open, whether a similar conclusion holds, if a dominating coefficient a_j exists, but $j\neq 0$.

In addition to the growth considerations of fast growing solutions of (3.3.4), published results about the oscillation of such solutions in the unit disc are practically non-existent. The only exception we know is a forth-coming paper [26] by Cao and Yi, devoted to considering zero distribution of solutions of $f''+A(z)f=0$, where the coefficient $A(z)$ is of infinite degree $D(f)=\infty$. In this case it is well known that $\rho_2(f)=\rho_M(A)$, and oscillation results parallel to what are known from the complex plane case immediately follow by applying the unit disc version of the Nevanlinna theory, see [26], Theorem 2.2 through Theorem 2.4. See also [28].

3.5. *Equations with slowly growing solutions*

As pointed out above, Nevanlinna theory becomes ineffective as soon as a solution f of a differential equation, say of (3.3.4), is slowly growing in the rough sense that the growth of a solution is not essentially faster than the growth of coefficients. Indeed, it may happen that the growth of solution is slower than that of the coefficients, as shown by the equation $f^{(n)} = (1-z)^{-\alpha} f = 0$, the solutions of which are bounded in the unit disc, provided $\alpha < n$. In the case of slowly growing solutions, complex function spaces appear to be the correct tool. The key questions regarding the growth may be formulated as follows, see [70], Section 1:

(1) Providing the coefficients a_j, $j = 0, \dots, n-1$ in (3.3.4) belong to a certain analytic function space (possibly depending on j), determine the function space(s) where solutions of (3.3.4) belong to.

(2) Providing that solutions f of (3.3.4) belong to a certain analytic function space, determine the function space(s) where the coefficients a_j belong to.

In what follows, the first problem here is called the *direct growth problem*, while the second is termed as the *inverse growth problem*. Concerning these two problems, the key results, see [70], may be expressed as follows:

THEOREM 3.5.1. *Let f be a non-trivial solution of* (3.3.4) *with analytic coefficients a_j, $j = 0, \dots, n-1$, in the unit disc $\mathbb{D}$. Then we conclude that*

(1) *$f \in N^p$, provided $1 \leqslant p < \infty$ and $a_j \in A^{p/(n-j)}$ for all $j = 0, \dots, n-1$, or $a_j \in A^p_{p(n-j-1)}$ for all $j = 0, \dots, n-1$,*

(2) *$f \in N$, provided $-1 < \alpha < 0$ and $a_j \in H^{1/(n-j)}_{(\alpha+1)(n-j)}$ for all $j = 0, \dots, n-1$,*

(3) *f is of finite degree $D(f)$, provided $a_j \in H^{1/(n-j)}_{n-j}$ for all $j = 0, \dots, n-1$,*

(4) *f is of finite order $\rho(f) \leqslant \alpha$, provided $0 < \alpha < \infty$ and $a_j \in A^{1/(n-j)}_{\alpha}$ for all $j = 0, \dots, n-1$, or $a_j \in A^1_{n-j-1+\alpha}$ for all $j = 0, \dots, n-1$,*

(5) *f is of finite order $\rho(f) \leqslant \alpha$, provided $\alpha > 0$ and $a_j \in H^{1/(n-j)}_{(\alpha+1)(n-j)}$ for all $j = 0, \dots, n-1$.*

Similarly, for the inverse problem, we obtain

THEOREM 3.5.2. *Let f be a non-trivial solution of* (3.3.4) *with analytic coefficients a_j, $j = 0, \dots, n-1$, in the unit disc $\mathbb{D}$. Then we conclude that*

(1) *The coefficients $a_j \in \bigcap_{0<p<1/(n-j)} A^p$ for all $j = 0, \dots, n-1$, provided all non-trivial solutions $f \in N$,*

(2) *the coefficients $a_j \in \bigcap_{0<p<1/(n-j)} H^p_{1/p}$ for all $j = 0, \dots, n-1$, provided all non-trivial solutions f are of finite degree $D(f)$,*

(3) *the coefficients $a_j \in \bigcap_{0<p<1/(n-j)} A^p_{\alpha}$ for all $j = 0, \dots, n-1$, provided all non-trivial solutions f are of finite order $\rho(f) \leqslant \alpha$,*

(4) *the coefficients $a_j \in \bigcap_{0<p<1/(n-j)} H^p_{(\alpha+1)/p}$ for all $j = 0, \dots, n-1$, provided $0 \leqslant \alpha < \infty$ and all non-trivial solutions f are of finite order $\rho(f) \leqslant \alpha$.*

For a quick, not quite complete, overview of the preceding two theorems, see the table in [70], Section 1. See also [70], Section 4, for a number of inclusions between the function spaces applied here.

Refining the reasoning used to prove Theorems 3.5.1(4) and 3.5.2(3), one may indeed even prove the following characterization, see [105]:

THEOREM 3.5.3. *All solutions f of the linear differential equations* (3.3.4) *satisfy $\rho(f) \leqslant \alpha$ if and only if the coefficients $a_j \in \bigcap_{0<p<1/(n-j)} A_\alpha^p$ for all $j = 0, \dots, n-1$.*

A slight improvement has been proved in [105] as follows:

THEOREM 3.5.4. *Denoting by $\mathbb{A}_\alpha^p$ the space of analytic function f in the unit disc $\mathbb{D}$ such that* $\alpha = \inf\{t \geqslant 0;\ f \in \bigcap_{0<s<p} A_t^s\}$, *we conclude that all non-trivial solutions f of* (3.3.4) *satisfy*

$$\min\left\{\alpha_0, \min_{j=1,\dots,n-1}\left\{\alpha_j + \frac{k(\alpha_0 - \alpha_j)}{j}\right\}\right\} \leqslant \rho(f) \leqslant \max_{j=0,\dots,n-1} \alpha_j,$$

provided the coefficients $a_j \in \mathbb{A}_{\alpha_j}^{1/(n-j)}$ for all $j = 0, \dots, n-1$.

Moreover, making use of the standard order reduction procedure, and using the same notations as in the preceding theorem, we conclude

THEOREM 3.5.5. *If $q \in \{0, \dots, n-1\}$ is the smallest index such that $\alpha_q = \max_{j=0,\dots,n-1} \alpha_j$, then each solution base of* (3.3.4) *possesses at least $n-q$ linearly independent solutions f of order $\rho(f) = \alpha_q$.*

Replies to the direct problem under the requirement that all solutions of (3.3.4) belong to, say H_p^∞, are not included in the preceding theorems. This type of recent investigations may be found in [71]. Main results in this important paper can be collected as follows:

THEOREM 3.5.6. *Given $0 < \delta < 1$, for every $p > 0$ there exists a constant $\alpha = \alpha(p, n) > 0$ such that if the coefficients a_j of* (3.3.4) *satisfy*

$$\sup_{|z| \geqslant \delta} \left|a_j(z)\right| \left(1 - |z|^2\right)^{n-j} \leqslant \alpha \tag{3.5.14}$$

for $j = 0, \dots, n-1$, then all solutions f of (3.3.4) *are in the weighted Hardy space H_p^∞. In particular, the conclusion remains true, if the supremum in* (3.5.14) *is taken over the whole unit disc $\mathbb{D}$.*

Proving the next theorem, see also [71], one has to make use of the Carleson measure, and the related notion of a Carleson box

$$S(I) := \left\{z \in \mathbb{D};\ \frac{z}{|z|} \in I, 1 - |I| \leqslant |z|\right\}$$

attached to a subarc of the unit disc boundary $\partial\mathbb{D}$ such that the arc length $|I| \leqslant 1$.

THEOREM 3.5.7. *Given* $0 < \delta < 1$, *all solutions* f *of* (3.3.4) *belong to the space* $\mathcal{D}^p \cap H_p^\infty$, *provided one of the following conditions hold*:

(1) *For every* $0 < p \leqslant 2$, *there exists a constant* $\alpha = \alpha(p, n)$ *such that the coefficients* a_j *satisfy the condition*

$$\sup_{\zeta \geqslant \delta} \int_{\mathbb{D}} \left|a_j(z)\right|^p \left(1 - |z|^2\right)^{p(n-j)-1} \frac{1 - |\zeta|^2}{|1 - \bar{\zeta} z|^2} \, \mathrm{d}\sigma_z \leqslant \alpha$$

for all $j = 0, \ldots, n-1$.

(2) *For every* $0 < p \leqslant 2$, *there exists a constant* $\beta = \beta(p, n)$ *such that the coefficients* a_j *satisfy the condition*

$$\sup_{0<|I|\leqslant \delta} \int_{S(I)} \left|a_j^k(z)\right|^p \left(1 - |z|^2\right)^{p(n+k-j)-1} \mathrm{d}\sigma_z \leqslant \beta$$

for all $j = 0, \ldots, n-1$ *and all* $k = 0, \ldots, n-1$.

For additional results of similar type as the two theorems above, see [144]. We also refer to [43] for results concerning the growth of $A(z)$, provided f is an α-normal solution of $f^{(k)} + A(z) f = 0$.

4. Non-linear differential equations in a complex domain

4.1. *Introductory remarks*

We first recall three key results, repeatedly used in studying non-linear algebraic differential equations in the complex plane, namely those called as the Clunie, Mohon'ko and Valiron–Mohon'ko lemmas. In this section, we mostly refer to [107], where complete proofs and references to the original works can be found.

We start with the Clunie lemma, see [107], Lemma 2.4.2:

THEOREM 4.1.1. *Let* f *be a meromorphic solution of*

$$f^n P(z, f) = Q(z, f),$$

where $P(z, f), Q(z, f)$ *are polynomials in* f *and its derivatives with meromorphic coefficients, say* $a_\lambda, \lambda \in I$, *such that* $m(r, a_\lambda) = S(r, f)$ *for all* $\lambda \in I$. *If the total degree of* $Q(z, f)$ *in* f *and its derivatives is* $\leqslant n$, *then*

$$m\big(r, P(z, f)\big) = S(r, f).$$

REMARK. Observe that there are numerous variants of this theorem in the literature, see e.g. [107], Section 2.4. Perhaps the most general version may be found in a forth-coming paper [192] by Yang and Ye. This version reads as follows:

THEOREM 4.1.2. *Let f be a meromorphic solution of*

$$S(z,f)P(z,f)=Q(z,f),$$

where $S(z,f)$ is a polynomials in f, and $P(z,f)$, $Q(z,f)$ are differential polynomials in f, all three with small coefficients $a(z)$ in the sense of $m(r,a)=S(r,f)$. If the degree of $S(z,f)$ is greater or equal to the total degree of $Q(z,f)$ in f and its derivatives, then $m(r,P(z,f))=S(r,f)$.

We next proceed to the Mohon'ko lemma, see [107], Proposition 9.2.3:

THEOREM 4.1.3. *Let f be a meromorphic solution of an algebraic differential equation*

$$P(z,f,f',\dots,f^{(n)})=0, \tag{4.1.1}$$

where P is a polynomial in $f,f',\dots,f^{(n)}$ with meromorphic coefficients small with respect to f. If a complex constant c does not satisfy Eq. (4.1.1), *then*

$$m\left(r,\frac{1}{f-c}\right)=S(r,f).$$

In this case as well, there are several variants in the literature. We recall here the following version, due in this generality to Ishizaki and Yanagihara [95]:

THEOREM 4.1.4. *Let f be a meromorphic solution of an algebraic differential equation* (4.1.1), *with meromorphic coefficients small with respect to f. Moreover, let $Q(z,f)$ be an irreducible polynomial in f with meromorphic coefficients small with respect to f. If the function elements determined by equation $Q(z,f)=0$ do not satisfy Eq.* (4.1.1), *then we have for $Q=Q(z,f(z))$ that $m(r,1/Q)=S(r,f)$.*

REMARK. The Ishizaki–Yanagihara variant of the Mohon'ko lemma has not been used very often in the theory of complex differential equations. However, we believe the importance of this version has been underestimated.

To close this section, we recall the Valiron–Mohon'ko theorem, see [107], Theorem 2.2.5:

THEOREM 4.1.5. *Let f be a meromorphic function, and let $R(z,f)=P(z,f)/Q(z,f)$ be an irreducible rational function in f with meromorphic coefficients small with respect to f. Then the characteristic function of $R(z,f(z))$ satisfies*

$$T\bigl(r,R(z,f)\bigr)=dT(r,f)+S(r,f),$$

where $d:=\max(\deg_f P(z,f),\deg_f Q(z,f))$.

4.2. *Malmquist type theorems*

Malmquist type theorems essentially contain necessary existence conditions for meromorphic solutions of algebraic differential equations that are fast growing with respect to the coefficients of the equation. The original version, due to Malmquist [125] in 1913, reads as follows:

THEOREM 4.2.1. *If a differential equation of the form*

$$f' = R(z, f),$$

where $R(z, f)$ is rational in both arguments and irreducible in f, admits a transcendental meromorphic solution, then the equation reduces to a Riccati differential equation

$$f' = a_0(z) + a_1(z)f + a_2(z)f^2$$

with rational coefficients.

Proving this theorem with the aid of the Nevanlinna theory is almost trivial, just making use of the Valiron–Mohon'ko theorem and comparing the characteristic functions of both sides of the equation. Yosida was the first one to offer this type of proof in 1933. Introducing the notion of a *small function* $\alpha(z)$ with respect to another function f by the requirement $T(r, \alpha) = S(r, f)$, where $S(r, f)$ stands for a quantity $o(T(r, f))$ as $r \to \infty$ outside of a possible exceptional set of finite linear measure, a slight improvement easily follows by the same reasoning:

THEOREM 4.2.2. *If a differential equation of the form*

$$(f')^n = R(z, f), \tag{4.2.2}$$

where $R(z, f)$ is rational and irreducible in f with meromorphic coefficients, admits a meromorphic solution f such that all coefficients of $R(z, f)$ are small with respect to f, then (4.2.2) *reduces into*

$$(f')^n = \sum_{j=0}^{2n} \alpha_j(z) f^j, \tag{4.2.3}$$

where at least one of the coefficients $\alpha_j(z)$ does not vanish identically.

In fact, the reduced equation (4.2.3) may still be reduced further. This reduction was first made by Steinmetz [169] in the basic case of rational coefficients, then partially extended to the case of meromorphic coefficients by von Rieth [185], and finally completed in [62]. In the general case (with non-rational coefficients), the proof in [62] makes use of a slight extension of the Hayman–Miles theorem estimating $T(r, f)$ in terms of $T(r, f')$ in a set of positive lower logarithmic density, see [60] and [62], Lemma D:

THEOREM 4.2.3. *If a differential equation of the form* (4.2.2), *where* $R(z, f)$ *is rational and irreducible in* f *with meromorphic coefficients, admits a meromorphic solution* f *such that all coefficients of* $R(z, f)$ *are small with respect to* f, *then* (4.2.2) *reduces by a suitable non-singular Möbius transformation* $f = (\alpha y + \beta)/(\gamma y + \delta)$ *into one of the following equation types* (*or an integer power of one of these*):

$$y' = a(z) + b(z)y + c(z)y^2, \tag{4.2.4}$$

$$(y')^2 = a(z)\big(y - b(z)\big)^2(y - \tau_1)(y - \tau_2), \tag{4.2.5}$$

$$(y')^2 = a(z)(y - \tau_1)(y - \tau_2)(y - \tau_3)(y - \tau_4), \tag{4.2.6}$$

$$(y')^3 = a(z)(y - \tau_1)^2(y - \tau_2)^2(y - \tau_3)^2, \tag{4.2.7}$$

$$(y')^4 = a(z)(y - \tau_1)^2(y - \tau_2)^3(y - \tau_3)^3, \tag{4.2.8}$$

$$(y')^6 = a(z)(y - \tau_1)^3(y - \tau_2)^4(y - \tau_3)^5, \tag{4.2.9}$$

where $\tau_1, \tau_2, \tau_3, \tau_4$ *are complex constants, and the coefficients* $a(z), b(z), c(z)$ *are small meromorphic functions. Moreover,* $a(z)$ *does not vanish identically in* (4.2.5)–(4.2.9).

As pointed out by Steinmetz in [169], examples of all six types in Theorem 4.2.3 with a meromorphic solution such that the coefficients are small may easily be constructed.

Somewhat similar considerations concerning the following two differential equations

$$(f')^n = q(z)P(f)P_0(f')(f - z)^m \tag{4.2.10}$$

and

$$(f')^n = q(z)\mathrm{e}^{P_1(z)}P(f)(f - z)^m, \tag{4.2.11}$$

where q is a rational function, P, P_0, P_1 are polynomials, $P_0 \neq 0$ and m, n are natural numbers, have been made by Ishizaki and Wang in [94]. We remark that these differential equations have a certain interest in the field of complex dynamics, as shown by Bergweiler, Terglane and Wang. As in the case of Malmquist–Yosida equations, existence of transcendental meromorphic solutions implies that the equations reduce to certain special forms:

THEOREM 4.2.4. *If Eq.* (4.2.10) *admits a transcendental meromorphic solution, then* (4.2.10) *reduces to one of the following special forms*:

$$f' = q(z)(f - z),$$

$$f' = q(z)(f - z)^2,$$

$$f' = q(z)(f - \tau_1)(f - z),$$

$$(f')^2 = q(z)(f - \tau_1)(f - z)^2,$$

$$(f')^2 = q(z)(f - \tau_1)(f - \tau_2)(f - z)^2,$$

where τ_1, τ_2 *are distinct complex constants.*

THEOREM 4.2.5. *If Eq.* (4.2.11) *admits a transcendental meromorphic solution, then* (4.2.11) *reduces to one of the following special forms*:

$$\begin{aligned}
&f' = q(z)\mathrm{e}^{P_1(z)}(f - z),\\
&f' = q(z)\mathrm{e}^{P_1(z)}(f - z)^2,\\
&f' = q(z)\mathrm{e}^{P_1(z)}(f - \tau_1)(f - z),\\
&(f')^2 = q(z)\mathrm{e}^{P_1(z)}(f - \tau_1)(f - z)^2,\\
&(f')^2 = q(z)\mathrm{e}^{P_1(z)}(f - \tau_1)(f - \tau_2)(f - z)^2,
\end{aligned}$$

where τ_1, τ_2 *are distinct complex constants.*

Concerning first order differential equations in general, first recall a classical theorem due to L. Fuchs:

THEOREM 4.2.6. *If the solutions of a differential equation*

$$P(z, f, f') := \sum_{j=0}^{n} A_j(z, f)(f')^j = 0 \tag{4.2.12}$$

where $P(z, f, f')$ *is an irreducible polynomial in* f, f' *with analytic coefficients, is free of movable singularities other than poles, then*

$$\deg_f A_j(z, f) \leqslant 2(n - j).$$

In particular, $A_0(z, f)$ *is independent of* f.

We remark in this connection that the notion of *movable singularities* has had wide use in the theory of complex differential equations, although it is not easy to find a rigorous definition in the literature. We recall the following one due to Bieberbach in [23]: Considering a complex differential equation (D), let S_D be the set of those points z_0 where at least one of the solutions of (D) has a singularity other than a pole. Then (D) is *free of movable singularities*, if the interior of S_D is empty. Isolated points in S_D are called *fixed singularities* of (D).

Somewhat surprisingly, the assertion as in Theorem 4.2.6 results while extending Theorem 4.2.2 to equations of type (4.2.12). This extension is called to be of the second Malmquist theorem type, see [126] for the original paper and [38], Theorem 6. To find a rigorous proof of this result, see [38], Sections 2–4. In a form corresponding to the previous versions of the (first) Malmquist theorem, we may write

THEOREM 4.2.7. *If a differential equation of the form* (4.2.12), *where the left-hand side* $P(z, f, f')$ *is an irreducible polynomial in* f, f' *with meromorphic coefficients, admits a meromorphic solution* f *such that all coefficients are small with respect to* f, *then* $\deg_f A_j(z, f) \leqslant 2(n - j)$. *In particular,* $A_0(z, f)$ *is independent of* f.

As pointed out by A. Eremenko in [38], the preceding way of considering a solution f of a differential equation such that all coefficients are small with respect to f, may easily be expressed in a slightly more general form. To this end, let $\varphi : [0, \infty) \to (0, \infty)$ satisfy $\log r = \mathrm{O}(\varphi(r))$ as $r \to \infty$, and denote by $\mathcal{M}_\varphi$ the family of all meromorphic functions that satisfy $T(r, f) = \mathrm{O}(\varphi(r))$ as $r \to \infty$ outside of a possible exceptional set E, depending on f, of finite linear measure. As one may easily see, $\mathcal{M}_\varphi$ is an algebraically closed field. Supposing now that all coefficients of $P(z, f, f')$ are in $\mathcal{M}_\varphi$, we say that a solution f of Eq. (4.2.12) is *admissible*, provided $f \notin \mathcal{M}_\varphi$. We may now reformulate Theorem 4.2.7 as follows, see [38], Theorem 6, and [86], Section 4:

THEOREM 4.2.8. *If a differential equation of the form* (4.2.12), *where the left-hand side $P(z, f, f')$ now is an irreducible polynomial in f, f' with meromorphic coefficients in $\mathcal{M}_\varphi$, admits a meromorphic solution $f \notin \mathcal{M}_\varphi$, then*

$$\deg_f A_j(z, f) \leqslant 2(n - j).$$

In particular, $A_0(z, f)$ is independent of f.

It remains now to consider such issues as the growth, value distribution, factorization etc. of the special types of differential equations described above with fast growing meromorphic solutions. As an example of such results we recall the following theorem due to S. Bank and R. Kaufman in [11]:

THEOREM 4.2.9. *Let f be a transcendental meromorphic solutions of the Malmquist–Yosida equation* (4.2.2) *with polynomial coefficients. Then the order $\rho(f)$ is either zero, or a positive multiple of* $1/2$, *or a positive multiple of* $1/3$. *Conversely, any such number appears as the order of growth of a transcendental meromorphic solution in the plane of such Eq.* (4.2.2).

Observe that the assertion of Theorem 4.2.9 remains valid for all first-order algebraic differential equations with polynomial coefficients, as shown by Eremenko in [40].

Concerning Malmquist type theorems in the second order case, it would be natural to ask for a complete list of differential equations of type

$$f'' = R(z, f, f'), \tag{4.2.13}$$

where $R(z, f, f')$ is rational in f, f' with meromorphic coefficients, such that all the coefficients (4.2.13) are small with respect to some solution f that does not satisfy first order differential equations of type (4.2.12), save for a possible Möbius transformation type change of variable in f. The requirement not to satisfy a first order algebraic differential equations is quite obvious, since almost arbitrarily complicated second order differential equations may be derived from (4.2.12) by differentiation. It has been conjectured that the existence of a fast growing solution implies that (4.2.13) reduces to

$$f'' = L(z, f)(f')^2 + M(z, f)f' + N(z, f), \tag{4.2.14}$$

where $L(z, f), M(z, f), N(z, f)$ are rational in f with small meromorphic coefficients, save for a Möbius transformation in f. In this full generality, the problem remains open, and we are aware of just one result that could be called as a second order Malmquist type theorem:

THEOREM 4.2.10. *If Eq.* (4.2.13), *where* $R(z, f, f')$ *is rational in all of its arguments, possesses a meromorphic solution* f *of infinite order, then* (4.2.13) *reduces into* (4.2.14).

Observe that the proof in [120] is quite different to the usual Malmquist theorem reasoning based on Nevanlinna theory; this time the well known Zalcman lemma and some pointwise derivative estimates due to Barsegian will be applied. Observe as well that such a solution f cannot satisfy a first-order algebraic differential equation by the classical Gol'dberg theorem [50], see Theorem 4.7.1.

Except for the preceding Theorem 4.2.10, all results below related to the second order Malmquist type topic are restricted to considering equation (4.2.14) under the assumption that all coefficients are small with respect to a meromorphic solution f. We recall two results of this type:

THEOREM 4.2.11. (See [172], Theorem 2.) *Writing* (4.2.14) *in the form*

$$P_3(z, f)f'' = P_2(z, f)(f')^2 + P_1(z, f)f' + P_0(z, f),$$

where P_0, P_1, P_2, P_3 *are relatively prime polynomials with rational coefficients, suppose that* f *is a transcendental meromorphic solution. Then*

$$\deg_f P_3 \leqslant 4, \quad \deg_f(fP_2 - 2P_3) \leqslant 3, \quad \deg_f P_1 \leqslant 4, \quad \deg_f P_0 \leqslant 6.$$

These bounds are best possible as shown by [172], Example 1.

THEOREM 4.2.12. (See [121], Theorem 1.) *Suppose that* $L(z, f), M(z, f), N(z, f)$ *in Eq.* (4.2.14) *are rational in both arguments, and suppose that* f *is a transcendental meromorphic solution of* (4.2.14). *Moreover, we assume that*

$$L(z, f) = \frac{a_n(z)f^n + \cdots + a_s(z)f^s}{b_m(z)f^m + \cdots + b_r(z)f^r},$$

where either $m - n < 1$ *or* $r - s > 1$. *Then* $\rho(f) < \infty$.

Concerning this last result, the simple example $f(z) = \exp(e^z)$ solving $ff'' - (f')^2 - ff' = 0$ shows that the assumptions $m - n < 1, r - s > 1$ cannot be deleted simultaneously.

In the autonomous case, Liao and Ye [122] were able to extract the possible types with fast growing solutions as follows:

THEOREM 4.2.13. *If the differential equation* (4.2.14) *with constant coefficients possesses a transcendental meromorphic solution* f *of order* $\rho(f) > 2$, *then the equation reduces into one of the following nine special cases*:

$$f'' = \sum_{j=1}^{4} \frac{1}{f-a_j}\left(\frac{1}{2}(f')^2 + C_j\right) + b_0 f' + c_2 f^2 + c_1 f + c_0, \tag{4.2.15}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\big((f')^2 + B_1 f' + C_1\big) + \frac{1}{f-a_2}\left(\frac{1}{2}(f')^2 + C_2\right) \\ & + \frac{1}{f-a_3}\left(\frac{1}{2}(f')^2 + C_3\right) + b_0 f' + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.16}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\left(\frac{1}{2}(f')^2 + C_1\right) + \frac{1}{f-a_2}\left(\frac{1}{2}(f')^2 + C_2\right) \\ & + \frac{1}{f-a_3}\left(\frac{1}{2}(f')^2 + C_3\right) + (b_1 f + b_0) f' \\ & + c_3 f^3 + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.17}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\left(\frac{2}{3}(f')^2 + B_1 f' + C_1\right) + \frac{1}{f-a_2}\left(\frac{2}{3}(f')^2 + B_2 f' + C_2\right) \\ & + \frac{1}{f-a_3}\left(\frac{2}{3}(f')^2 + B_3 f' + C_3\right) + b_0 f' + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.18}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\left(\frac{1}{2}(f')^2 + C_1\right) + \frac{1}{f-a_2}\left(\frac{3}{4}(f')^2 + B_2 f' + C_2\right) \\ & + \frac{1}{f-a_3}\left(\frac{3}{4}(f')^2 + B_3 f' + C_3\right) + b_0 f' + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.19}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\left(\frac{1}{2}(f')^2 + C_1\right) + \frac{1}{f-a_2}\left(\frac{2}{3}(f')^2 + B_2 f' + C_2\right) \\ & + \frac{1}{f-a_3}\left(\frac{5}{6}(f')^2 + B_3 f' + C_3\right) + b_0 f' + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.20}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\big(A_1 (f')^2 + B_1 f' + C_1\big) + \frac{1}{f-a_2}\big(A_2 (f')^2 + B_2 f' + C_2\big) \\ & + (b_1 f + b_0) f' + c_3 f^3 + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.21}$$

$$\begin{aligned} f'' = {} & \frac{1}{f-a_1}\big(A_1 (f')^2 + B_1 f' + C_1\big) + (b_1 f + b_0) f' \\ & + c_3 f^3 + c_2 f^2 + c_1 f + c_0, \end{aligned} \tag{4.2.22}$$

$$f'' = (b_1 f + b_0) f' + c_3 f^3 + c_2 f^2 + c_1 f + c_0, \tag{4.2.23}$$

where a_j *for* $j = 1, \dots, 4$, B_j, C_j *for* $j = 1, \dots, 4$, b_1, b_0 *and* c_j $j = 1, \dots, 3$ *are complex constants, and where either* $A_1 = A_2 = 1/2$ *or* $A_1 = (k_1 - 1)/k_1$, $A_2 = (k_2 - 1)/k_2$ *and* $(k_1 - 1)/k_1 + (k_2 - 1)/k_2 = (k+1)/k$ *for some integers* $k_1 \geqslant 2, k_2 \geqslant 2$ *and* $k \geqslant 3$.

The proof of Theorem 4.2.13 again relies, among other tools, to the Zalcman lemma. As shown by concrete examples, see [122], all nine cases in Theorem 4.2.13 may actually appear. The non-autonomous case of (4.2.14) remains open. Although it is quite likely that a result similar to Theorem 4.2.13 would remain true for fast growing solutions, some modification of the proof in [122] is definitely needed.

In addition to Theorems 4.2.11 and 4.2.13, special cases of (4.2.14) have been treated in a number of papers: The case when $L(z, f) = M(z, f) \equiv 0$ has been due to Wittich in [188], the case $M(z, f) = N(z, f) \equiv 0$ by von Rieth [185] and the case $L(z, f) \equiv 0$ by Steinmetz [171]. Ishizaki gives in [92] a fairly detailed treatment of the case $L(z, f) \equiv 0$ as well as of the general case, provided $L(z, f) \equiv 1$. See also [91].

Finally, we mention that a number of Malmquist type theorems have been proved for complex differential equations of higher order. As a typical example of such theorems, we recall

THEOREM 4.2.14. (See [46], Satz 5, [169], p. 21.) *If a differential equation of the form*

$$P(z, f, f', \dots, f^{(n)}) := \sum_{\lambda \in I} c_\lambda(z) f^{\lambda_0} (f')^{\lambda_1} \cdots (f^{(n)})^{\lambda_n} = R(z, f) \tag{4.2.24}$$

where $P(z, f, f', \dots, f^{(n)})$ *is an irreducible polynomial in* $f, f', \dots, f^{(n)}$ *with meromorphic coefficients, and* $R(z, f)$ *is rational and irreducible in* f *with meromorphic coefficients, admits a meromorphic solution* f *such that all coefficients of* P *and* R *are small with respect to* f, *then* $R(z, f)$ *is a polynomial in* f *and*

$$\deg_f R(z, f) \leqslant \Delta := \max_{\lambda \in I} (\lambda_0 + \lambda_1 + \cdots + \lambda_n).$$

4.3. *Riccati differential equation*

As the most simple non-linear differential equation, the Riccati differential equation

$$f' = a(z) + b(z) f + c(z) f^2 \tag{4.3.25}$$

deserves a separate treatment, not the least due to its important role in optimal control (usually in the frame of matrix-valued complex differential equation). First recall (Corollary 1.2.7) that all solutions of (4.3.25) are meromorphic functions whenever the coefficients $a(z), b(z), c(z)$ are entire. The situation becomes more complicated, if the coefficients (or at least one of them) is non-entire meromorphic. Since (4.3.25) may be transformed to

$$f' = A(z) + f^2 \tag{4.3.26}$$

by a simple transformation, which preserves the meromorphic nature of the coefficients, we mostly refer to (4.3.26) in what follows.

THEOREM 4.3.1. *If the Riccati differential equation* (4.3.26) *admits three distinct meromorphic solutions in the complex plane, then all solutions of* (4.3.26) *are meromorphic, and they constitute a one-parameter family* $\mathfrak{F} := (f_C)_{C\in\mathbb{C}}$, *with* $f_0 \notin \mathfrak{F}$ *for one of the three original solutions. Two distinct meromorphic solutions are sufficient to imply the same conclusion, if for one of them, say* f_0, $2f_0$ *has integer residues at all of its poles.*

Concerning the number of distinct meromorphic solutions of (4.3.26) deduced from the properties of the meromorphic coefficient $A(z)$, the following conclusions can be made, see [9] and [107], Section 9.1:

THEOREM 4.3.2.

(1) *If* $A(z)$ *is entire, or if all poles* ζ *of* $A(z)$ *are double such that the coefficients of their Laurent expansions*

$$A(z) = \sum_{j=-2}^{\infty} b_{j+2}(z-\zeta)^j$$

satisfy that (i) $4b_0 = 1 - m^2$ *for a natural number* $m \geqslant 2$ *and that* (ii) *the determinant condition* (2.4.25) *holds, then all solutions of* (4.3.26) *are meromorphic.*

(2) *If* $A(z)$ *has a simple pole, then* (4.3.26) *has at most one meromorphic solution.*

(3) *If* $A(z)$ *has a double pole such that the coefficients of the Laurent expansion at this pole does not satisfy the conditions in* (1), *then* (4.3.26) *has at most two meromorphic solutions. If, however,* $4b_0 = 1$, *then at most one meromorphic solution exists.*

(4) *If* $A(z)$ *has a multiple pole of odd multiplicity, then* (4.3.26) *has no meromorphic solutions. If* $A(z)$ *has multiple poles only, all with even multiplicity, then two meromorphic solutions may exist.*

As an example of Theorem 4.3.2(1), see [108], we may consider equation $f'' - \frac{2}{\cos^2 z} f = 0$ which has two linearly independent meromorphic solutions $f_1(z) = \tan z$ and $f_2(z) = 1 + z\tan z$. By a simple computation, we see that the conditions given in Theorem 4.3.2(1) are satisfied. For a collection of examples covering the remaining cases, see [9].

It is well known that all meromorphic solutions of (4.3.25) are of finite order whenever $a(z), b(z), c(z)$ are rational functions. As for the case of non-rational coefficients, very few papers only may be found. We may refer to [9] for the normalized equation (4.3.26) with $A(z)$ entire, and to [166] for (4.3.26) with $A(z)$ doubly periodic meromorphic. Concerning basic observations for the value distribution of meromorphic solutions of (4.3.25), resp. of (4.3.26), see [107] and [9].

What also remains more or less open, is to consider Riccati differential equation in the unit disc. We mention here a result due to Yamashita [191]:

THEOREM 4.3.3. *Assume that in Eq.* (4.3.25) *the coefficients belong to the following weighted Hardy spaces*: $a(z) \in H_2^\infty, b(z) \in H_1^\infty, c(z) \in H_0^\infty$. *If* $\inf_{z\in\mathbb{D}} |c(z)| > 0$, *then each holomorphic solution* f *of* (4.3.25) *may be expressed in the form* $f = Cy''/y'$, *where* $C > 0$ *is a constant and* y *is a non-constant function analytic and univalent in* $\mathbb{D}$.

Quite likely, some more results could be easily obtained by recalling the close connection between (4.3.26) and the linear differential equation $u'' + A(z)u = 0$, and making use of the results described in Section 3.

4.4. *Schwarzian differential equations*

A Schwarzian differential equation means a complex differential equation of the form

$$\big(S(f)(z)\big)^p = R(z, f) = \frac{P(z, f)}{Q(z, f)}, \tag{4.4.27}$$

where p is a natural number, $R(z, f)$ is an irreducible rational function in f with meromorphic coefficients, and where

$$S(f)(z) := \left(\frac{f''}{f'}\right)' - \frac{1}{2}\left(\frac{f''}{f'}\right)^2 = \frac{f'''}{f'} - \frac{3}{2}\left(\frac{f''}{f'}\right)^2 \tag{4.4.28}$$

is the standard Schwarzian derivative of a meromorphic function f. We also denote by d the degree of $R(z, f)$ with respect to f.

Observe first that Schwarzian differential equations are closely related with Riccati differential equations. In fact, denote by $\mathcal{R}$ the class of meromorphic functions f that satisfy a Riccati differential equation (4.3.25), $f' = a(z) + b(z)f + c(z)f^2$, such that the coefficients $a(z), b(z), c(z)$ are small with respect to f. Moreover, denote by $\mathcal{R}_k$ the subclass of functions f in $\mathcal{R}$ that have k Picard exceptional values. Then we have the following result, see [92], Theorem 3.2.13:

THEOREM 4.4.1. *If* $f \in \mathcal{R}_k$ *with* $k = 1, 2$, *then* f *also satisfies a Schwarzian differential equation* (4.4.27) *with* $p = 1$ *and* $d = 4 - 2k$. *If* $f \in \mathcal{R}_0$, *then* f *also satisfies a Schwarzian differential equation* (4.4.27) $p = 1$ *and* $d = 4$ *or* $d = 2$ *depending on whether* $D(z) = b(z)^2 - 4a(z)c(z) \equiv 0$, *or not.*

Not surprisingly, the Schwarzian differential equation (4.4.27) has similarities with the Malmquist–Yosida differential equation (4.2.2). To this end, compare the following theorem from [90] with Theorem 4.2.3:

THEOREM 4.4.2. *Suppose that the autonomous Schwarzian differential equation*

$$S(f)(z) = R(f) \tag{4.4.29}$$

admits a transcendental meromorphic solution f. *Then for a non-singular Möbius transformation* $u := (\alpha f + \beta)/(\gamma f + \delta)$ *with complex coefficients, Eq.* (4.4.29) *reduces into one of the following forms*:

$$\begin{aligned}
S(u)(z) &= c\frac{(u-\sigma_1)(u-\sigma_2)(u-\sigma_3)(u-\sigma_4)}{(u-\tau_1)(u-\tau_2)(u-\tau_3)(u-\tau_4)},\\
S(u)^3(z) &= c\frac{(u-\sigma_1)^3(u-\sigma_2)^3}{(u-\tau_1)^3(u-\tau_2)^2(u-\tau_3)},\\
S(u)^3(z) &= c\frac{(u-\sigma_1)^3(u-\sigma_2)^3}{(u-\tau_1)^2(u-\tau_2)^2(u-\tau_3)^2},\\
S(u)^2(z) &= c\frac{(u-\sigma_1)^2(u-\sigma_2)^2}{(u-\tau_1)^2(u-\tau_2)(u-\tau_3)},\\
S(u)(z) &= c\frac{(u-\sigma_1)(u-\sigma_2)}{(u-\tau_1)(u-\tau_2)},\\
S(u)(z) &= c,
\end{aligned}$$

where $c \in \mathbb{C}$, *and* $\tau_1, \tau_2, \tau_3, \tau_4, \sigma_1, \sigma_2, \sigma_3, \sigma_4$ *are complex constants so that* $\tau_1, \tau_2, \tau_3, \tau_4$ *are mutually distinct.*

As for the corresponding non-autonomous case, Ishizaki proved in [93] the following corresponding result:

THEOREM 4.4.3. *Suppose that the non-autonomous Schwarzian differential equation* (4.4.27) *with* $p = 1$ *admits a transcendental meromorphic solution* f *such that all meromorphic coefficients of* $R(z, f)$ *are small with respect to* f. *Then either the solution* f *satisfies a Riccati differential equation with small meromorphic coefficients, or* f *satisfies a first order algebraic differential equation*

$$(f')^2 + B(z, f)f' + A(z, f) = 0 \tag{4.4.30}$$

where $A(z, f), B(z, f)$ *are polynomials in* f *with small meromorphic coefficients, or* (4.4.27) *reduces to one of the following two forms*:

$$\begin{aligned}
S(u)(z) &= \frac{P(z,u)}{(f+b(z))^2},\\
S(u)(z) &= c(z),
\end{aligned}$$

where $b(z), c(z)$ *are small meromorphic functions.*

REMARK. In the case of (4.4.30), we may apply a transformation $f = \tau + 1/w$, $\tau \in \mathbb{C}$, to obtain a first order differential equation of the same form (4.4.30) such that $\deg_w B(z, w) \leqslant 1$, $\deg_w A(z, w) \leqslant 3$.

For corresponding results concerning a more complicated Schwarzian type differential equation, see [87].

The growth of solutions of Schwarzian differential equations has been treated by Liao and Ye recently, see [123]:

THEOREM 4.4.4. *Suppose f is a transcendental meromorphic solution of a Schwarzian differential equation* (4.4.27) *with polynomial coefficients. Then the following conclusions hold*:

(1) *If f has a Picard exceptional value, then $\rho(f)$ is finite.*
(2) *If f has two completely ramified values, then $\rho(f) \leqslant 2$.*
(3) *If the Schwarzian equation under consideration is autonomous, then $\rho(f) \leqslant 2$.*
(4) *If the right-hand side of* (4.4.27) *is independent of f, hence a rational function $R(z) = P(z)/Q(z)$, then f is of finite order and*

$$\rho(f) = (m - n + 2p)/(2p) > 0,$$

where $m = \deg P$, $n = \deg Q$. In particular, if $R(z)$ reduces to a constant, then $\rho(f) = 1$.

Finally, we recall the following result concerning the deficiencies, see [90]:

THEOREM 4.4.5. *Suppose f is a transcendental meromorphic solution of a Schwarzian differential equation* (4.4.27) *with polynomial coefficients, and let $\alpha_1, \dots, \alpha_s$ be distinct complex numbers. Then*

$$d + 2p \sum_{j=1}^{s} \delta(\alpha_j, f) \leqslant 4p,$$

where $d = \deg_f R(z, f)$.

4.5. *Painlevé differential equations*

The following problem has been originally proposed by Picard: Given $R(z, f, f')$ rational in its arguments, what are the second order ordinary differential equations in the complex plane of the form $f'' = R(z, f, f')$ having the property that the singularities other than poles of any solution of this equation depend on the equation in question only and not on the constants of integration? Painlevé (1895) and Gambier (1910) proved that there are fifty canonical equations of this form having the property proposed by Picard. This property is known as the *Painlevé property*, and the differential equations possessing this property are called equations of Painlevé type. Among the fifty equations obtained by Painlevé and Gambier, the following six equations, known as the *Painlevé equations,* are the most interesting ones:

$$f'' = 6f^2 + z, \tag{4.5.31}$$

$$f'' = 2f^3 + zf + \alpha, \tag{4.5.32}$$

$$f'' = \frac{(f')^2}{f} - \frac{1}{z}f' + \frac{1}{z}(\alpha f^2 + \beta) + \gamma f^3 + \frac{\delta}{f}, \tag{4.5.33}$$

$$f'' = \frac{(f')^2}{2f} + \frac{3}{2}f^3 + 4zf^2 + 2(z^2 - \alpha)f + \frac{\beta}{f}, \tag{4.5.34}$$

$$\begin{aligned} f'' = {} & \frac{3f-1}{2f(f-1)}(f')^2 - \frac{1}{z}f' + \frac{1}{z^2}(f-1)^2\left(\alpha f + \frac{\beta}{f}\right) \\ & + \frac{\gamma f}{z} + \frac{\delta f(f+1)}{f-1}, \end{aligned} \tag{4.5.35}$$

$$\begin{aligned} f'' = {} & \frac{1}{2}\left(\frac{1}{f} + \frac{1}{f-1} + \frac{1}{f-z}\right)(f')^2 - \left(\frac{1}{z} + \frac{1}{z-1} + \frac{1}{f-z}\right)f' \\ & + \frac{f(f-1)(f-z)}{z^2(z-1)^2}\left(\alpha + \frac{\beta z}{f^2} + \frac{\gamma(z-1)}{(f-1)^2} + \frac{\delta z(z-1)}{(f-z)^2}\right), \end{aligned} \tag{4.5.36}$$

where $\alpha, \beta, \gamma, \delta$ are arbitrary complex constants. In fact, solutions of eleven other equations of the Painlevé type may be expressed in terms of solutions of the preceding six Painlevé equations, while the thirty-three remaining Painlevé type equations are solvable in terms of solutions of linear differential equations, or in terms of elliptic functions.

The Painlevé equations form a vast field nowadays, in particular due to the importance of their solutions as a kind of non-linear special functions. The field has remarkably extended during the last four decades or so, very much falling in the borderline area of mathematical physics. As for some of the several key references of this field, we may refer to [42,96,137] and [139], as examples of a number of excellent references. In this connection, we restrict ourselves to considering solutions of Painlevé differential equations from the point of view of complex analysis, with main emphasis in the value distribution of solutions of Painlevé differential equations. In particular, we omit results related to asymptotic representations, integrability, Riemann–Hilbert problems, isomonodromic deformations and inverse scattering theory. Moreover, we do not go in detail into Bäcklund transformations.

The Painlevé property proposes that solutions of the six Painlevé equations are close to being meromorphic functions in the complex plane. It is easy to find non-meromorphic solutions to the third (4.5.33), fifth (4.5.35) and sixth (4.5.36) Painlevé equations. However, for (4.5.33) and (4.5.35) the only possible non-polar singularities are at $z = 0$ and $z = \infty$, and hence the transformation $z = \exp t$ might result in an equation with meromorphic solutions only, while for (4.5.36) with three possible fixed singularities at $z = 0, 1, \infty$, such a transformation does not work. Indeed, applying for (4.5.33) a slightly different transformation, we obtain the modified forms of (4.5.33) and (4.5.35):

$$f'' = \frac{(f')^2}{f} + \alpha f^2 + \gamma f^3 + \beta e^z + \frac{\delta e^{2z}}{f} \tag{4.5.37}$$

and

$$\begin{aligned} f'' = {} & \left(\frac{1}{2f} + \frac{1}{f-1}\right)(f')^2 + (f-1)^2\left(\alpha f + \frac{\beta}{f}\right) + \gamma e^z f \\ & + \frac{\delta e^{2z} f(f+1)}{f-1}. \end{aligned} \tag{4.5.38}$$

Making use of these modified forms, we may express the meromorphic nature of the solutions of Painlevé equations as follows:

THEOREM 4.5.1. *All local solutions of first* (4.5.31), *second* (4.5.32), *modified third* (4.5.37), *fourth* (4.5.34) *and modified fifth* (4.5.38) *Painlevé equations can be analytically continued to single-valued meromorphic functions in the complex plane.*

THEOREM 4.5.2. *Given* $z_0 \in \mathbb{C} \setminus \{0, 1\}$ *and a local solution* f *of the sixth Painlevé equation* (4.5.36) *in a neighborhood of* z_0, f *can be analytically continued without restriction to a possible multi-valued meromorphic function in* $\mathbb{C} \setminus \{0, 1\}$.

The original idea of proving these two theorems goes back to Painlevé in the early years of 1900’s. The first paper containing a rigorous function theoretic proof for these two theorems, as far as we know, is due to Hukuhara [88]. Unfortunately, this paper was never published, and so it remained quite unknown. Recently, several papers appeared to offer such proofs, see [80–83,140,161] and [173].

After the meromorphic nature of the Painlevé functions has been settled, natural questions about their growth and value distribution appears. Concerning the growth, we have the following results:

THEOREM 4.5.3. *All solutions* f *of the first Painlevé equation* (4.5.31) *are of order* $\rho(f) = 5/2$.

The inequality $\rho(f) \geqslant 5/2$ goes back to Mues and Redheffer [130]. The inverse inequality is due to Steinmetz [174] and Shimomura [163], see also [162]. The proofs are quite different: Steinmetz makes use of a clever rescaling of the equation, while Shimomura carries through a careful analysis of solutions f in the neighborhoods of its poles, making use of the fact that f is the derivative of a meromorphic function.

THEOREM 4.5.4. *The solutions* f *of the second Painlevé equation* (4.5.32), *resp. the fourth Painlevé equation* (4.5.34), *are either rational functions, or transcendental meromorphic of order* $\rho(f)$ *satisfying* $3/2 \leqslant \rho(f) \leqslant 3$, *resp.* $2 \leqslant \rho(f) \leqslant 4$.

This theorem was proved almost simultaneously in three papers with different methods, see [84,162] and [175].

Observe that the rational solutions for Painlevé differential equations may be completely characterized and constructed. Indeed, (4.5.31) admits no rational solutions, while for (4.5.32), there exists exactly one rational solution if and only if the parameter $\alpha \in \mathbb{Z}$. This solution vanishes identically, when $\alpha = 0$, from which the rational may be computed, at least in principle, for $\alpha \neq 0$, by the standard Bäcklund transformations, see [51], p. 100. Concerning the fourth Painlevé equation (4.5.34), rational solutions exist if and only if the parameters α, β satisfy that $\alpha = n_1$ and either $\beta = -\frac{2}{9}(6n_2 - 3n_1 + \varepsilon)^2$, or $\beta = -2(1 + 2n_3 - n_1)^2$, where n_1, n_2, n_3 are integers, and $\varepsilon = \pm 1$, see [131] and [195]. As for solutions f of order $\rho(f) = 3/2$ for (4.5.32), a family of such solutions, called Airy solutions, are characterized by the fact that they simultaneously satisfy a first order algebraic differential equation, see [51], Theorem 21.1. Concerning solutions f of order $\rho(f) = 2$ for (4.5.34), several such families of solutions are known, see [51], Chapter 6. Concerning the rational solutions of (4.5.33), (4.5.35) and (4.5.36), the case of (4.5.35) has been solved by Kitaev, Law and McLeod, see [103], while for (4.5.33) and (4.5.36), we refer to [195] by Yuan and Li. Of course, rational solutions of (4.5.33) and (4.5.35) result in special solutions f of (4.5.37) and (4.5.38) of growth $T(r, f) = O(r^K)$ for some $K > 0$.

Proceeding to the growth of modified third and fifth Painlevé equations, Shimomura proved in [165] that these are of finite hyper-order:

THEOREM 4.5.5. *All solutions f of* (4.5.37), *resp. of* (4.5.38), *satisfy $T(r, f) = O(\exp(\Lambda r))$ for some strictly positive real number Λ independent of f.*

The best possible value of Λ remains unknown. However, a result in [19], Theorem 2, indicates that $\Lambda \leqslant 2$ might be true. Moreover, a similar bound might be true for solutions f of the sixth Painlevé equation as well in the sense that around an essential singularity of f, the local hyper-order of f might be $\leqslant 2$.

We now proceed to considering the value distribution of Painlevé functions. The key quantities to be considered in this connection are their defect and ramification indices, including constant and slowly moving targets. We remark that most results of this type presently known are, quite likely, not best possible. Therefore, we mention a number of open questions in this connection. Most of the results referred to below are due to Shimomura, [155,158,156,159].

THEOREM 4.5.6. *Let f be a solution of* (4.5.31), *and let α be a meromorphic function small with respect to f. Then the defect of f, resp. the ramification index of f, with respect to α satisfies the inequality $\delta(\alpha, f) \leqslant 1/2$, resp. $\vartheta(\alpha, f) \leqslant 5/12$. If $\alpha(z) \equiv a \in \mathbb{C}$, then $\vartheta(a, f) \leqslant 1/6$. Finally, $\delta(\infty, f) = 0$.*

REMARK. Theorem 4.5.6 is originally due to Schubart and Wittich [151]. In the proof due to Shimomura [158], the key ingredients are the classical Clunie and Mohon'ko lemmas, see Theorems 4.1.1 and 4.1.3. The proof in [158] immediately implies that $\delta(\alpha, f) = 0$, if $\alpha(z)$ does not satisfy the same Painlevé equation (4.5.31). As the existence of such a pair

$\alpha(z)$, $f(z)$ seems quite unlikely, we conjecture that actually $\delta(\alpha, f) = 0$. Also, it is not known whether the upper bound 1/6 for the ramification index is best possible.

THEOREM 4.5.7. *Let f be a solution of* (4.5.32), *and let α be a meromorphic function small with respect to f. Then the defect of f with respect to α satisfies the inequality $\delta(\alpha, f) \leqslant 1/2$.*

REMARK. As for the second Painlevé equation (4.5.32), results related to the ramification indices $\vartheta(\alpha, f)$ of their solutions seem to be missing in the literature.

Concerning the modified third Painlevé differential equation (4.5.37), we first restrict our considerations to its fast growing solutions f meaning that $S(r) \equiv r$ is small with respect to f, see [155]. Secondly, we assume that the parameters satisfy the conditions $(\alpha, \gamma) \neq (0, 0)$ and $(\beta, \delta) \neq (0, 0)$.

THEOREM 4.5.8. *Under the conditions just described, $\delta(a, f) = 0$ for each extended complex number a. If the parameter $\delta \neq 0$, then $\vartheta(a, f) \leqslant 1/4$ for each complex number $a \neq 0$, while if $\delta = 0$ and $\beta \neq 0$, then $\vartheta(a, f) \leqslant 1/6$.*

REMARK. If $(\alpha, \gamma) = (0, 0)$ or $(\beta, \delta) = (0, 0)$, then (4.5.37) reduces to a Riccati differential equation with constant coefficients as shown in [81], pp. 326–327. In this case, defects and ramification indices may easily be computed.

Defect indices for solutions of the fourth Painlevé equation (4.5.34) become more complicated. We first consider the case of constant targets:

THEOREM 4.5.9. (See [170].) *Let f be a transcendental solution of* (4.5.34), *and let $a \in \mathbb{C} \cup \{\infty\}$ be a constant target value. We then have*:

(1) *If $a = \infty$, then $\delta(a, f) = 0$.*
(2) *If $(\beta, a) \in \mathbb{C} \times \mathbb{C} \setminus (0, 0)$, then $\delta(a, f) = 0$.*
(3) *If $(\beta, a) = (0, 0)$, and f satisfies one of the two Riccati differential equations $f' = \mp(f^2 + 2zf)$, then $\delta(a, f) = 1$.*
(4) *If $(\beta, a) = (0, 0)$, and f does not satisfy the two Riccati differential equations $f' = \mp(f^2 + 2zf)$, then $\delta(a, f) \leqslant 1/2$.*

PROOF. The case (1) is an immediate consequence of the Clunie lemma. As for the case (2), we refer to [170]. For the remaining cases (3) and (4), one needs to solve the Riccati differential equations $f' = \mp(f^2 + 2zf)$. Since $f = 0$ is a solution trivially, and for each $c \in \mathbb{C}$,

$$f_c^{\pm}(z) = \exp(\mp z^2)\left(c \pm \int_0^z \exp(\mp t^2)\,\mathrm{d}t\right)^{-1}$$

also solves the corresponding Riccati equation, we conclude by [107], Proposition 9.1.1, that the complete solution family is given by $\{0\} \cup \{f_c^{\pm};\, c \in \mathbb{C}\}$. Since the functions $f_c^{\pm}$ are entire, the conclusion of (3) immediately follows. The remaining case (4) is again referred to [170]. □

Observe that the solutions $f_c^{\pm}$ above are of order $\rho(f_c^{\pm}) = 2$.

Proceeding to the case of slowly moving targets, first recall the expression

$$H_\nu(z) = (-1)^\nu \exp(z^2)\left(\frac{\mathrm{d}}{\mathrm{d}z}\right)^\nu \exp(-z^2)$$

for the Hermite polynomials with $\nu \in \mathbb{N} \cup \{0\}$. For these values of ν, the Hermite–Weber differential equation $u'' + (-\frac{t^2}{4} + \nu + \frac{1}{2})u = 0$ admits two linearly independent solutions $D_\nu(t)$, $D_{-\nu-1}(\mathrm{i}t)$, for which we have

$$D_\nu(\sqrt{2}\,z) = 2^{-\nu/2}\exp(-z^2/2)H_\nu(z).$$

Let us first consider the special parameter values $\alpha = -(n + \frac{1}{2} \pm \frac{1}{2})$, $\beta = -2(n + \frac{1}{2} \mp \frac{1}{2})^2$ in (4.5.34), where $n \in \mathbb{Z}$ can be given arbitrarily. Then equation (4.5.34) possesses a one-parameter family $f_{n,c}^{\mp}$, $c \in \mathbb{C} \cup \{\infty\}$, of solutions, expressible in the form

$$f_{n,c}^{\mp}(z) = -z \mp \frac{\eta_{n,c}'(z)}{\eta_{n,c}(z)},$$

where

$$\eta_{n,c}(z) = c_1 D_n(\sqrt{2}\,z) + c_2 D_{-n-1}(\sqrt{2}\,\mathrm{i}z), \quad c = c_1/c_2.$$

These solutions are of order $\rho(f_{n,c}^{\mp}) = 2$, except for $g_n^{\mp} := f_{n,\infty}^{\mp}$, provided $n \in \mathbb{N} \cup \{0\}$ and for $g_n^{\mp} := f_{n,0}^{\mp}$, provided $n \in -\mathbb{N}$. These exceptional cases are rational solutions. For more details, as well as for proofs of the next theorem, see [159]. Again, the proofs strongly rely on using the Clunie and Mohon'ko lemmas.

THEOREM 4.5.10. *Let f be an arbitrary transcendental solution of* (4.5.34), *and let g be a meromorphic function small with respect to f. Then we have*:

(1) *If $(f, g) = (f_{n,c}^{\mp}, g_n^{\mp})$ is one of the special pairs determined above, then $\delta(g, f) = 1$.*

(2) *Otherwise, $\delta(g, f) \leqslant 1/2$, if $\beta \neq 0$, and $\delta(g, f) \leqslant 3/4$, if $\beta = 0$.*

REMARK. It is not known, whether the inequalities in Theorem 4.5.10(2) are best possible. Moreover, possible results concerning the ramification indices remain open.

The value distribution of (4.5.38) has been treated by Shimomura in [156]. First observe that if the parameters γ, δ vanish, then (4.5.38) easily reduces to a Riccati differential equation, see [82], pp. 134–135. Similarly as in the case of (4.5.37), we have to restrict ourselves to fast growing solutions f of (4.5.38), again meaning that $S(r) \equiv r$ is small with respect to f. We first have to extract two special families of solutions: (1) Provided

$\alpha = 0$ and $-4\beta\delta + (\gamma \pm (-2\delta)^{1/2})^2 = 0$, then (4.5.38) possesses a one-parameter family of solutions

$$f^{\pm}_{\gamma,\delta,c}(z) := \exp\bigl(\kappa_{\pm} z \mp (-2\delta)^{1/2} \mathrm{e}^{z}\bigr)\left(c - \kappa_{\pm} \int_0^z \exp\bigl(-\kappa_{\pm} s \pm (-2\delta)^{1/2}\mathrm{e}^{s}\bigr)\,\mathrm{d}s\right),$$

where $\kappa_{\pm} = 1 \pm \gamma(-2\delta)^{-1/2}$ and $c \in \mathbb{C}$, denoted by $\mathcal{V}$ below. (2) Provided $\beta = 0$ and $-4\alpha\delta + (-\gamma \pm (-2\delta)^{1/2})^2 = 0$, then (4.5.38) possesses a one-parameter family of solutions

$$g_{\gamma,\delta,c}(z) := 1/f_{-\gamma,\delta,c}(z),$$

denoted by $\mathcal{W}$ below.

THEOREM 4.5.11. *Let f be a fast growing solution of* (4.5.38), *where its parameters satisfy* $(\gamma, \delta) \neq (0, 0)$, *and let a be an extended complex number. Then* $\delta(a, f) = 0$ *except of the following special cases*:

(1) *If $f \in \mathcal{V}$, then $\delta(\infty, f) = 1$ and if $f \in \mathcal{W}$, then $\delta(0, f) = 1$.*
(2) *If $\alpha = 0$ and $f \notin \mathcal{V}$, then $\delta(\infty, f) \leqslant 1/2$ and if $\beta = 0$ and $f \notin \mathcal{W}$, then $\delta(0, f) \leqslant 1/2$.*
(3) *If $\alpha + \beta = 0$, $\gamma = 0$ and $\delta \neq 0$, then $\delta(-1, f) \leqslant 1/2$.*

THEOREM 4.5.12. *Let f be a fast growing solution of* (4.5.38), *where its parameters satisfy* $(\gamma, \delta) \neq (0, 0)$, *and let $a \in \mathbb{C} \setminus \{0, 1\}$. Then we have the following inequalities*:

(1) *If $\delta \neq 0$, then $\vartheta(a, f) \leqslant 1/4$.*
(2) *If $\delta = 0$ and $\gamma \neq 0$, then $\vartheta(a, f) \leqslant 1/6$.*
(3) *If $\alpha + \beta = 0$, $\gamma = 0$ and $\delta \neq 0$, then $\vartheta(-1, f) = 0$.*

Moreover,

(4) *If $\alpha \neq 0$, resp. $\beta \neq 0$, resp. $\delta \neq 0$, then $\vartheta(\infty, f) = 0$, resp. $\vartheta(0, f) = 0$, $\vartheta(1, f) = 0$. Finally, if $\delta = 0$, then $\vartheta(1, f) = 1/2$.*

REMARK. As one may immediately see, ramification indices remain open in several special cases. It is also not known, whether the inequalities in the preceding two theorems are best possible.

Concerning finally (4.5.36), the most general of the Painlevé equations, it would be natural to study the defects and the ramification indices of its solutions locally in a neighborhood of their essential singularities. However, this has not been done, so far we know.

Finally, it is worth to be mentioned that for meromorphic Painlevé functions, the asymptotic inequality in the second main theorem of Nevanlinna theory becomes an asymptotic equality, see [51], Section 11.

We then proceed to considering, shortly, higher order Painlevé equations, i.e. certain hierarchies of equations, each starting from a given Painlevé equation. Equations in these hierarchies all possess the Painlevé property. However, it remains open to what extent the solutions of these differential equations indeed are meromorphic functions. We conjecture that the solutions to equations in the hierarchies built on the first, second and fourth

Painlevé equations are meromorphic, but there is no proof for this by now. Also, considering the growth and value distribution of meromorphic solutions of higher order Painlevé equations is still very much an open area of research. The first and the second Painlevé hierarchies only have been somewhat treated presently, see below.

To define the *first Painlevé hierarchy*, let $D = \mathrm{d}/\mathrm{d}z$ be the usual differential operator, and D^{-1} stand for its inverse. Defining $d^1(f) := -4f$, we inductively determine

$$d^{n+1}(f) := D^{-1}\big((D^3 - 8fD - 4f')d^n(f)\big).$$

Then we may consider the equations in the first Painlevé hierarchy defined as

$$d^{n+1}(f) + 4z = 0. \tag{4.5.39}$$

It is immediate to observe that we get the first Painlevé equation (4.5.31) from the case $n = 1$, while for $n = 2$ we obtain

$$f^{(4)} = 20ff'' + 10(f')^2 - 40f^3 + z,$$
